For the relief of these strictures there are two principal methods of treatment. One is called internal urethrotomy, or cutting of the stricture internally ; the other, external urethrotomy, or by going directly through the skin. The latter method is applicable in the deep cases which are almost impermeable to the urine, and impassable to an instrument. Internal urethrotomy is practically the same thing as divulsion, or forcible dilatation, with this exception, that in internal urethotomy the blade of the instrument makes a clean, sharp incision, and is more liable to be followed by hæmorrhage than it is with divulsion, which tears tissues apart, and by lacerating vessels prevents hæmorrhage that otherwise might follow. For that reason, I prefer a divulsing instrument for the membranous portion, and a sharp cutting instrument for the spongy portion. A properly made instrument should have a small eyelet for the whalebone guide. It is quite uncertain whether I can pass this instrument through the membranous stricture

or not, for the simple reason that its size prevents it. [Professor Hamilton at this juncture informed the class that Thompson's expander had been taken from the instrument case and could not be found, consequently he had an imperfect instrument to do his work.] I shall try to pass this instrument alongside the filiform guide. You notice I pass in one successively after the other. I do this in order to fill the lacunæ that form in these strictures. By passing the filiform bougies one after the other and twisting the instrument on its axis, it will enable us to pass one of them into the bladder. What is rather unusual, I have succeeded in passing this instrument alongside of the guide and it is now in the bladder. We have the pleasure of seeing the urine flow. It not infrequently happens after divulsion, that we have a flap of membrane torn, which slips down directly in front of the point of the instrument, on reintroduction, and we are simply pushing the point of the bougie against it. I have here succeeded in reaching the neck of the bladder by using an ordinary lithotomy staff which has an almost prostatic curve. I have now succeeded in passing the instrument into the bladder and the urine is escaping. I think perhaps a soft catheter would be a desirable thing for this patient to use for a few hours. I shall now endeavor to make this wound in the mucous membrane as aseptic as possible, by injecting through it an antiseptic solution, filling the catheter with an antiseptic fluid. I shall prevent any infection in the wounded membrane as it passes out. The water will pass out of the eye of the catheter. The anterior portion of the penis can be easily irrigated by this tube. The old-fashioned urethral chill, about which we used to hear so much, has almost disappeared since the adoption of irrigation of the urethra by antiseptic fluids.

GLEET AND BUBO.

Dr. A. Hewson, in the surgical out-patient department of the Jefferson Hospital, prescribed for the bubo the local application of the following ointment:

℞ Ichthyol.....ʒ iv.
Lanoline.....ʒ jss.
M.

For the gleet:

℞ Hydrarg. bichlorid.....gr. ½.
Zinci sulph. carbolat.....ʒ ss.
Acid. boric.....ʒ jss.
Liq. hydrogen peroxid.....f ʒ iiij.
Aquæ destillat.....ad f ʒ vj.
M. Use injection in the morning and evening.

ALOPECIA AREATA AND TRICHORRHEXIS.

By A. BLASCHKO, M. D.,
BERLIN, GERMANY.

Gentlemen: Until a few years ago, the principal diagnostic feature of alopecia areata, in distinction to other forms of disease resulting in a loss of the hair, was that there appeared to be no pathological change either of the scalp or of the hairs themselves which fell out, the latter seeming to be microscopically identical with hairs that fell out under natural conditions. There seemed to be no evidences of inflammation, no formation of scars, and no breaking of the hairs. A few authors, notably, Michelson, called attention to the fragility of these hairs and also to their splitting, but these peculiarities were found so seldom as to have but little weight. In recent years, however, Behrend and Besnier have noticed two peculiar characteristics, namely, the appearance of an air space in the root of the hairs, and the absence of the hair marrow. These appearances do not always occur in atrophic hairs, but nevertheless may be considered as pathogenic evidences of alopecia areata, or at least as a frequent accompanying symptom. These authors also draw attention to the frequency with which they observed a breaking off of the hair close to the scalp—a variation of the disease which Besnier designates *pelade à cheveux fragiles.* Bazin refers to the same as *fausse pelade,* and Lailler as *pedale pseudotondante.* The last two authors have mistakenly attributed the cause of this trouble to the trichophyton tonsurans. A similar, and perhaps the same disease, has been recently described by Nimier as folliculitis tonsurans (microbian), and who observed the disease epidemic among certain French troops. Vaillard and Vincent also have shown microscopically, as well as by breeding and inoculations, the parasitic character of the cases examined by them.

It was somewhat over a year ago that my attention was also called to this symptom of the breaking off of the hairs in alopecia areata, and since then I have found it present in at least seventy-five per cent. of the cases coming under my attention. It seems to be particularly frequent on the periphery of the affected parts, and occurs in a greater or less degree. Undoubtedly we may regard this as a characteristic symptom of the disease.

Three months ago the patient before you came to me for treatment, and I was surprised at the number of broken hairs; indeed, trichorrhexis was the most prominent

symptom of the disease. The entire scalp was covered with innumerable short stumps of hair which looked as though they had been cut close to the scalp with scissors. There were no symptoms of inflammation. The appearance of the case since two months ago has greatly changed. In place of the numerous bald spots, covered with a hairy stubble, you now see the parts covered with young hairs, and exhibiting the typical picture of convalescing alopecia areata. The new hairs can be seen in almost every stage of development—some tender, fine and almost without pigment, others coarser and pigmented, while the hair stumps have greatly diminished in number. I have, however, been able to definitely prove, by this case, that in alopecia areata the hairs break off before they fall out.

One of these hair stumps if epilated and examined will be found to have a normal root, an atrophic and unpigmented shaft, and just below the point of breakage a portion will be found to still contain pigment. The point of breakage is either blunt or else ragged and frayed. Some of the hairs—those which have been affected the longest, will be found to be quite loose, and can be easily lifted out of their sockets. Others not broken will be found nicked, and in some the point of breakage when the upper portion has not yet fallen off will appear as two brooms thrust one within the other, as intrichorrhexis nodosa.

The question now arises as to the cause of this peculiar symptom of the breaking of the hairs.

Behrend and Besnier have sought to explain this abnormal fragility by a drying of them, which, in its turn may be due to circulatory disturbances, or a stoppage of the supply of nourishment to the hairs. Our knowledge of the subject, however, teaches us that a simple drying of the hairs cannot have this effect. The hairs are very hygroscopic, and are able to replace any loss of moisture by the absorption of moisture from the air. This can be easily proven by a simple experiment. Hairs may be placed upon hot plates, or upon a lamp chimney, and allowed to dry, but still one will find it impossible to kink or break a healthy hair—providing of course, it has not been burned. If taken from the hot surface it will soon replenish itself with moisture. Therefore, in order to explain this symptom of breaking off of the hairs, another possibility must be taken into consideration, viz., that while nutritive disturbances may take place, they result in not only a loss of moisture of the hair, but in an entire change of its bio-chemical compositition. The substance of the hair undergoes a physical change. The amount of fats, albuminoids, etc., contained in it are altered.

Here we would call attention to a very remarkable fact, which may be frequently demonstrated upon these diseased hairs, viz., the presence of numerous micro-organisms, which may be found microscopically and by breeding, not only in the shaft of the hair, but in the root, root sheath, and bulb; but in the last named place only when the hairs are very loose in their sheaths. The most varied forms of micro-organisms are found—cocci, small bacilli, round and oval bacteria—and we are led to the thought of a subsequent inoculation, and not a causative condition. This idea is strengthened by the fact that cultures of the sound hairs will remain sterile, while those, the diseased or broken hairs will develope the above named micro-organisms among others—and again when the point of breakage of the hair is placed in the culture, medium colonies will be developed. Now the theory might be advanced, that if morbid processes leading to a total atrophy of the hairs were caused by micro-organisms, these might also lead to the subsequent breakage of the already atrophic hairs. The number of micro-organisms found at the point of fracture, might prove very misleading in tending to confirm this theory. Nevertheless the possibility cannot be entirely discredited, that a certain micro-organism is the cause of the breakage of the already atrophied hairs. On the other hand, the question arises whether or not breakage is primary, and the atrophy secondary. This is, however, not the case, and the course of the disease proves it, and even the hairs that are only kinked, will be frequently found to have lost pigment, and be atrophied.

After all that has been said, we may condense the results of our experiences as follows:

Trichorrhexis is a very frequent, although perhaps not invariable symptom in the beginning of alopecia areata; and there occur cases in which the symptom is remarkably pronounced. Besnier's idea of creating through this symptom a new variation of alopecia arecta, is entirely untenable and incorrect. To what cause the breakage of the hairs may be ascribed, has not been proven. The possibility of a secondary action of a micro-organism cannot be entirely set aside. The entire disease is neither parisitary nor contagious, and differs, therefore, from the *pseudo-pelade* described by Vaillard and Vincent.

COMMUNICATIONS.

A CASE OF MALIGNANT DISEASE OF THE STOMACH IN WHICH GASTRO-ENTEROSTOMY WAS CONSIDERED*

By JOHN B. ROBERTS, M. D.

I desire to briefly report the result of a case in which I was only deterred from making preparation for gastro-enterostomy by the debilitated condition of the patient, but in which the post-mortem findings showed the inutility of such an operation. The delay which prevented me from subjecting the patient to the expense and anxiety of so serious an abdominal operation is so justified by the pathological conditions that it has caused me to present the specimen for examination.

Upon being summoned to another State for surgical consultation, I found a man about fifty-two years of age suffering from great pain in the epigastrium. He was vomiting large amounts of fluid. The temperature was normal, but the muscular weakness was great, and sleeplessness pronounced. The abdomen was distended with gas, and there was a marked prominence in the neighborhood of the left hypogastrium. The patient had suffered for about four years with dyspeptic symptoms, during which time he had been under the care of many physicians. He had recently been treated by lavage, which relieved the pain temporarily, and he had suffered with such obstinate constipation as made the attending physician think that there was some obstruction in the alimentary tract. It was this as well as the excessive pain that induced him to call in surgical aid.

The character of the vomiting, the situation of the prominence in the left hypogastrium, and the general aspect of the case made it very evident to me that it was one of dilatation of the stomach. I gave an opinion that it was very possible that there was malignant disease in the neighborhood of the pylorus; but it was impossible to determine the question because of the distended abdomen, and the diagnosis was hence left undecided. The administration of food by the mouth was stopped entirely, and enemata of peptonized milk combined with whiskey were given every two hours night and day. Lavage was continued to empty the stomach and relieve pain. This line of treatment was continued for about three weeks. The patient's discomfort was relieved, the pain disappeared, the vomiting discontinued, and the consequent reduction of tympany rendered it possible to detect a hard mass below the liver in the median line. The bowels in the mean time had become regular by the occasional administration of cascara. This for two weeks, however, was not needed, because of spontaneous evacuation of the bowels, probably due to the enemata. Miscroscopic examination of the vomited matter showed me that blood was present in the ejecta, and I now made a diagnosis of malignant disease.

At the end of three weeks small amounts of nourishment were given by the stomach. We commenced with a drachm of peptonized milk with a few drops of whiskey every two hours, and daily diminished the amount of food administered by the rectum. Gradually the amount of food taken into the stomach was increased until it reached three ounces every two hours. The prolonged rest during the period above mentioned seemed to have been beneficial to the stomach, so that the small amounts of food given at frequent intervals were digested without pain; there was no vomiting, though the tympany became more or less prominent.

At the time he began to take food by the mouth I told the patient that he had malignant disease of the stomach, and that exploratory examination was proper, with a view of determining whether an artificial opening could be made between the stomach and the intestine, or the growth removed. This was deferred until the strength of the patient should be somewhat improved under gastric alimentation. The patient, however, continued to lose ground, and died about a month after my first visit. When the food given by the stomach reached three and a half ounces he began to have pain.

The autopsy showed, as the specimen makes clear, malignant disease, infiltrating about one-fourth of the long diameter of the stomach, with several nodular masses at the pylorus. The pylorus, however, is sufficiently patulous to admit readily the introduction of a finger-tip. There was, therefore, no marked obstruction. The cardia is much thinned, while the middle portion of the stomach presents the normal thickness and characteristics. An adhesion has taken place between the stomach and the liver at the point where the growth is most marked.

Gastric dilatation had occurred secondarily to malignant disease of the pylorus. The only time at which it seems to me gastro-enterostomy would have been wise was previous to his coming under the care of Dr. H. A.

*Read before the Philadelphia County Medical Society, February 10, 1892.

Stout, who called upon me for assistance; and it is very doubtful if at any time the operation would have been beneficial. The pylorus, as shown at the autopsy, must have had an opening as large as would probably have been made had the operation in question been performed; and the infiltration of the wall of the stomach for one-third of its length would have made the area for an opening between the stomach and the intestine limited. An opening would have had to be made between the thinned and dilated portion of the stomach at the cardiac extremity and the large area infiltrated with malignant growth toward the pyloric end. This, of course, could have been done, but prolongation of life would probably not have been gained.

The facts that the man was walking about and attending to business and that the tumor presented no external manifestations make it extremely probable that an operation would not have been suggested previously to the time he came under the care of the physician who consulted me, except by an enthusiast.

I present one case partly because of the interesting character of the specimen, and partly as a contribution to a branch of abdominal surgery which is assuming increased importance.

The recent series of cases reported by Dr. N. Senn have been read by me with great interest; but the conclusion has almost been forced upon me that many of them were cases that scarcely justified operative procedure. Perhaps I am too conservative; but may it not be that he is too enthusiastic?

AN INQUIRY INTO THE BLOOD AND URINE OF THE INSANE.

In the *Journal of Mental Sciences* for October, 1890, Dr. J. Smith notes the lessened proportion of hæmoglobine among the insane, this peculiarity being greatest in cases of secondary dementia. It is not particularly marked in melancholia, general paralysis, and epilepsy. In spite of diminution in hæmoglobine and red corpuscles the specific gravity of the blood is increased, indicating abnormal density of the plasma. The quantity of urine is great in general paralysis, reduced in a secondary dementa, about normal in other forms of insanity, and apparently lessened in melancholia. Urinary solids exist abundantly in general paralysis, and are much diminished in secondary dementia, the other forms of mental disease presenting nothing unusual in this particular. Uric acid is excessive in general paralysis, epilepsy and dementia. There appears to be a slight excess of phosphoric acid in epilepsy.

CHRONIC ENDOMETRITIS.*

By J. M. BALDY, M. D.,

Professor of Gynæcology in the Philadelphia Polyclinic; Surgeon to Gynæcean Hospital; Gynæcologist to St. Agnes Hospital.

Of late years it has become the habit of gynecologists to consider almost all endometrical disease as symptomatic, and not an independent lesion. It is certainly true that many pelvic diseases are accompanied by an unhealthy condition of the endometrium; especially in pelvic inflammatory disorders the lining membrane of the uterus is so frequently affected as to have given rise to the supposition that it is either caused by the pelvic disease, or rarely occurs independent of it. In fact, such assertions are frequently made in print and on the floors of our societies. The temptation is strong to accept this theory, which appears at first blush to be so plausible, but which is nevertheless most fallacious. My daily experience is teaching me that endometritis as an independent disease is quite a common disorder, and is at the bottom of many of the discomforts suffered by women. The causes giving rise to this disease are much the same as those which originate vaginitis, and particularly salpingitis—specific infection and post-puerperal sepsis being the most prolific, and giving rise to the bulk of the cases. Oftentimes the beginning of the trouble can easily be traced to a child-birth or to an abortion. The woman has had a slow get up, and will give the history of some fever, or she has regained her usual health very slowly, and possibly not at all; she will have complained of a vaginal discharge since her confinement, when previously she had been free from this annoyance. The history may be that of an attack of specific infection. Sometimes the history in such a case is clear—a sudden appearance of a yellowish vaginal discharge, with swelling of the labia and burning micturition. At other times the evidence of specific infection is not entirely satisfactory, but it is quite notorious that women often become contaminated without giving it any particular attention, or the discomfort has been so slight as to be soon forgotten. In any event, if the disease be neglected and spreads to the cavity of the uterus, it soon spends its force and settles down to a chronic condition. It may or may not extend into

*Read before the Philadelphia County Medical Society, February 10, 1892.

the Fallopian tubes and cause a salpingitis and peritonitis. Should it do so, as is often the case, the removal of the appendages will not necessarily bring about a cure of the patient. In fact, this is the secret of the failure of laparotomy in many of the cases which are going from one clinic to another for relief. Even if the disease is complicated by pelvic disorders of an inflammatory nature, especially if the two arise from the same cause, it is well to first turn our attention to the endometritis, in which case a laparotomy may at times be avoided. In other words, certain cases, embracing the two diseases, the symptoms from the endometritis may overshadow those from the salpingitis; this is especially true of many instances in which the intra-peritoneal damage has not been very serious. In those cases where the intra-peritoneal inflammation has subsided, and only its products remain, the treatment of the endometrial inflammation, which, under these circumstances, is usually chronic, can be carried out with impunity if ordinary care be taken.

Of course, in the event of there being an acute or even a subacute pelvic inflammatory condition present, great care must be taken not to interfere with the uterus in any way, else an already bad condition of affairs may be made much worse, and even serious. In many patients, in whom there exists post-puerperal septic endometritis or specific endometritis, the disease has stopped short of the tubes, and has not involved either them or the peritoneum. These cases are quite common, and are daily overlooked. The women wander from one doctor's office to another, and finally, when their money is all gone, into the public clinics, seeking relief in vain. It is often a matter of surprise to me that many of them have never even had an examination made, but have been treated for months and years with drugs, or have been advised to use an injection of hot water. The hot water injections as usually given are worse than useless. Just sufficient water at a moderate temperature is used to a cause a congestion of the uterus and pelvis, which congestion is not relieved by the secondary effect of the hot water, *viz.:* the contraction and consequent driving away of the blood from the parts. These women suffer from continual uterine discharge more or less profuse; there is, perchance, a feeling of weight and heaviness in the pelvis, accompanied by backache; sometimes they feel weak and worn-cut. The menstrual function is disordered, being generally irregular and profuse; pain may or may not attend this function. These symptoms exist either alone or in various combinations, the only constant and reliable one being the uterine discharge. A local examination discloses an enlarged and heavy uterus, from the cervical canal of which an unhealthy thickish discharge is oozing. Oftentimes the cervix is eroded, and the mucous membrane of the everted lips, if the lips be everted, bleeds on being touched with a piece of cotton or an instrument. This hæmorrhagic condition is more apt to be present when the disease is still acute or subacute; but, nevertheless, it is at times seen in the chronic cases. In some instances the uterine body is comparatively normal to the touch so far as its consistency is concerned; again, it may be either too soft, or, what is more common, extremely hard, and even almost fibrous in character. These changes indicate that the disease is not altogether confined to the endometrium, but has invaded the structures comprising the uterine wall. It is no uncommon thing to see an endometritis and a metritis coexisting; in fact, in chronic cases it is rather the rule than the exception. The disease is almost always primarily an endometritis, and treatment which will cure this affection will be followed by a cure of the metritis almost as a matter of course. So much is this the rule that I have gotten to look on these two diseases as very much one and the same.

Where this condition of affairs exists—a large and abnormally heavy uterus—there is very apt to be a retro-displacement of the womb sooner or later. Whether or not all displacements which give rise to trouble are originally caused by uterine inflammations, it is a curious fact that it is a very rare thing to find a troublesome retro-displacement without either uterine or pelvic inflammatory diseases complicating it.

For the treatment of uncomplicated endometritis and metritis there are a variety of remedies, some of them quite effective, while many of them are useless, and are applied in a haphazard way. My own preference is to adopt the shortest and surest course of procedure. The woman is put under ether, the cervix is dilated, and the uterus thoroughly curetted; the uterine cavity is then washed out, and an application of Churchill's iodine made to its surface. If there is pretty free bleeding in consequence of those manipulations, the uterus is packed full of iodoform gauze, which is removed in the course of a day or two, as circumstances demand. Ergot may or may not be given by the mouth, the indications for its use being hæmorrhage or an enlarged heavy uterus. Usually, I give

a half drachm of the fluid extract, three times a day for a short period, gradually reducing the quantity until it is dispensed with altogether within about a week.

As to the steps of the operation: The patient is placed in the dorsal position, the dilatation is made with the Goodell rapid dilator after careful antiseptic precautions. I dilate usually only sufficient to introduce and manipulate my instruments easily—from three-quarters of an inch to an inch. Great care is taken to make the curettement a thorough one. All débris can be washed away, and the cavity cleansed by the use of the rectal nozzle of a Davidson syringe. The application of iodine follows immediately, it being applied with a long-nozzled uterine syringe. The patient is now returned to bed, and nothing more is done for a week or two, excepting to give absolute rest, hot water injections, and keep the bowels soluble, together with the ergot as indicated. I have not found the occasion to place a hard rubber drain in the uterus, as Wyle does, nor to pack it with iodoform gauze for a prolonged period, as Polk proposes. I find, if my dilatation has been properly made, that the cervical canal remains sufficiently patulous for the necessary drainage. The uterus will resent in one way or another the presence of a foreign body, and these procedures can only result in just so much more irritation and consequent discharge.

Some patients are cured altogether by this treatment; but, for the most part, in order to secure a thoroughly satisfactory result, treatment must be kept up for some little time after the woman is allowed to get out of bed. It is my habit, in these cases, to make an intra-uterine application of iodine about twice a week for a few weeks, then once a week, and finally to withdraw the treatment altogether; the hot water injection should be kept up twice a day throughout the whole course of treatment. It is not uncommon, where the endometrium has undergone a fungoid change, for the disease to return, and the whole treatment has thus to be gone through with a second time.

Many patients will not submit to this treatment, in which event it becomes necessary to resort to other methods of management. A prolonged course of intra-uterine treatment will, in many cases eventually bring about the same result. I do not maintain that iodine is the only remedy to be used for this purpose, but I have come to use it routinely for the reason that I have found no other drug which would give better results. It is not always advisable to use it in full strength, in which case it may with advantage be diluted with glycerine in the required proportions. Icthyol and all similar substitutes have only proven disappointing.

So much for the uncomplicated cases of endometritis. Where the disease is accompanied by a pelvic inflammatory condition the first question to settle is whether or not an abdominal section is to be performed for the removal of the appendages. If they are not sufficiently affected to call for the operation, and if the uterine symptoms predominate, and are very annoying, I have no hesitation in treating the uterine cavity. A long-nozzled uterine syringe may with safety be passed into the uterus, even in the presence of considerable pelvic disease, and a local application thus made. In these cases the strength of the material injected should be regulated by the amount of inflammation, as a strongly irritating fluid will be much more likely to cause trouble than the mere passage of the instrument itself. When the pelvic disease has been an old one and quiescent I have not hesitated in gently dilating the cervix and curetting the cavity of the uterus, nor have I ever had any trouble follow such procedure. In this class of patients there is an opportunity for the nicest kind of judgment, and if one be skilful and careful in selecting the proper cases the treatment may be followed by the greatest benefit. I am perfectly well aware that this is contrary to the teachings of many gynæcologists of the present day, but my own experience in these matters has opened my eyes to the fallacy of such ideas. If the gentlemen opposing the practice of intra uterine treatment would try it on some of their cases who continue to have enlarged uteri and a vaginal discharge after the removal of the appendages they would soon become convinced of its practical value, even in these cases.

The treatment of endometritis by electricity I have not touched upon, not that I do not approve of it, but because Dr. Massey follows me with a paper on that subject. It is especially valuable in those cases which refuse the above line of treatment.—(*For discussion, see Society Reports.*)

GONORRHEA.

METRITIS AS AN INITIAL LESION IN PELVIC DISEASE; ITS COMPLICATIONS AND TREATMENT BY ELECTRICITY.*

By G. BETTON MASSEY, M. D.

The attractive field recently opened to surgical gynæcologists by the discovery that the ovaries and tubes may be amputated without invariably resulting in the death of the patient, has caused an enormous preponderance of current medical literature to be directed toward diseases of these organs. So great has become the furor that little else is heard at our special societies but discussions on the wet specimens thus procured, which are brought in regularly in buckets by certain operators. This singular abundance of pathological material supplied by two organs out of an important group is calculated to make an onlooker who is, fortunately, free from what might be called the operative infection inquire carefully into its reasons. Granting the peculiarly peccant nature of these organs as a justification, it may be asked why resort should invariably be had to amputation rather than to a more conservative operation. It may be that there is such a thing as a wartime in this work, when, as in military surgery in the field, parts of Nature's handiwork are hastily removed that a more thoughtful conservatism would have restored to health.

But it is not my purpose to discuss at present the debatable question of the proper management of inflammatory conditions of the ovaries and tubes; they are merely alluded to at this time because it is my conviction that many ovaries and tubes have recently been removed when the real seat of trouble was within the uterus.[1] In examining for tender spots by the bimanual manipulation, it is exceedingly difficult to differentiate between a sensitive ovary and a tender uterus, and if one's mind is so constituted that the uterus is entirely ignored, and endometritis or metritis unthought of, a mistake is readily made. One operator declared some two years ago that he did not believe there was such a thing as endometritis. Dragging upon the tender uterus, as he did daily, in his endeavor to find salpingitis, he mistook the purport of the pain excited.

In contrast to this position it may be affirmed that inflammatory conditions of the uterus are the most frequent of all the local diseases of parous women and not infrequently found in virgins. More significant still, it may be said to be either the precedent condition or the nidus of many of the most formidable diseases in this locality, such as certain displacements, catarrhal salpingitis, pho-salpingitis, ovaritis, cancer of the cervix, fibrosis, and many other lesser troubles. How great, then, is the necessity for its early recognition and prompt treatment!

The classical studies of this disease found in the books are most instructive, although the pathological conditions described in the several varieties of endometritis are of but little clinical use to us, since we do not often study these cases in the dead-house, and as yet but few specimens have been presented at the societies. Whether the case is one of interstitial, follicular, or polypoid endometrites, it is, moreover, of secondary importance in face of the present apparently well-founded belief that they are all examples of that protean disease of mucous cavities—microbic invasion. The several forms of cervicitis, endocervicitis, endometritis, and interstitial metritis are clinically distinct and largely separable, it is true, but the fact should not be lost sight of that they are all alike microbic in origin, even subinvolution being septic or trauma-septic, and hence are all mere local variations of the same disease.

The recent developments of bacteriology teach us plainly, then, that simple endometritis—a bacterial colonization of the endometral gland—is the primal step in these progressive conditions. Whether the morbific germ is one of common staphylococci of pus or some other organism, it seems clear that to its conquest of the local phagocytes is due the hyperæmia, hypersecretion, and hyperplasia of the glandular substance of the endometrium, which, later, extends to other situations by either direct continuity of structure or by lymphatic absorption. The reason for the peculiar susceptibility of the uterine cavity to such invasions is easily conceived when we remember that the intrauterine mucosa is distinctly glandular—that the endometrium is, in fact, a gland rather than a mucous membrane.

The method by which the uterine cavity becomes the culture-medium of these infections deserves some consideration. On reviewing the conditions present, particularly

*Read before the Philadelphia County Medical Society, February 10, 1892.

[1] The grounds for this conviction are derived primarily from a number of cases of post-operative pain seen in private practice and at the Dispensary for Women at Fourth and Spruce streets. Many of these cases had enlarged and tender wombs when seen by me, and had either been made worse by the operation or left in an unchanged condition.

the ubiquity of pus-germs in the centres of population, one is disposed to ask why an infection of this region is not universal instead of the exception. The natural, healthy mucus and the temperature would seem to be an ever-present invitation. Why, then, are germs normally absent above the internal os, though so abundant below that point? The answer has never yet been given; but it can be none other than that of a body of sentinel phagocytic cells stationed in the cervical cavity to war upon morbific germs. Remove these sentinel cells, or lower their vitality, and the resistance they present is overcome by the outer hordes.

The ineffectiveness of these vital sentinels in puerperal infection is manifest. By a flank movement or brutal charge the seeds of destruction are planted well beyond the lines. An endometritis results, which is the cause rather than the effect of the subinvolution of the muscular fibres. In the nulliparous, and particularly in virgins, the method of invasion is not so clear, though we do not have to look far to find it. The prevalence of early stages of metritis—in other words, of endometritis— in perfectly pure virgins is a daily result of my inquiries. At sixteen, seventeen, and particularly between seventeen and twenty-three, in this climate, a uterine leucorrhœa is by no means uncommon in weak and delicate girls; and we do not have to adopt the harsh and generally untrue statement of Schroeder as quoted in the most recent work on this subject, Pozzi's *Gynœcology*, that the germs are introduced by masturbation. The condition of the general health of these patients is the real causal factor. The germs are always in the cervix normally unless the hymen be imperforate, and they are enabled to penetrate within the uterine cavity by reason of weakness on the part of the sentinel cells. A girl whose blood is impoverished by inherited weakness, to which is added the many imperfections in our methods of fashionable education, is in but a poor condition to marshal sentinels and defenses against any morbific attack. The logic of this view is sustained by the methods of many rational physicians in dealing with this condition in such cases. Let the blood-making organs once be restored to health, and the invaders, *if not too deeply intrenched*, will be driven out.

At its inception this affection is usually subacute, if we except the more virulent forms of puerperal metritis, and runs its course without material disturbances of temperature, like the analogous affections of the nasal cavity. Even after the disease has extended so far as the Fallopian tubes, with the production of muco-purulent accumulations, the temperature may still be normal. In my experience, an acute stage is lacking, the onward march of the affection being as insidious as it is gradual. Beginning as an endometritis or endocervicitis, the patient is only conscious at first of a leucorrhœa which becomes more abundant and irritating to the vagina and vulva, and should be the sign for active and intelligent interference on the part of her physician, though of late a do-nothing policy has been advocated by some. It has been said by an eminent authority that the womb has its natural secretions, like the nose. That is, of course, true, but it should be remembered that the nasal secretion is not normally muco-purulent; as soon as pus-corpuscles habitually occur in either secretion, the existence of a diseased condition is manifestly proven.

The subsequent stages and the effects of this catarrhal endometritis are natural consequences. Accompanying the hypertrophy of the endometrium into fungoid and cryptose conditions we have a direct stimulation of the connective-tissue cells of the parenchyma. Trophic changes in this situation and general fibrosis of the body of the uterus result. Coincidently, or at a later period, an extension upward along the mucous tract occurs, and salpingitis, ovaritis, or both, add their burdens to the suffering woman. I shall not recount the local symptoms of this conglomerate affection beyond the statement that at various periods in its course we find changes in the quantity and quality of the secretions, erosion of the os from irritating discharges, hypertrophy and tenderness of the cervix and corpus, combined with a reasonable movability of the uterus as a whole. With these facts you are all familiar. On the reflex symptoms some doubt has been thrown of late, but the best proof that pains down the limbs, in the abdomen, and in the back, with or without nervous prostration, are caused by this "irritable" uterus is given by the disappearance of such symptoms as a result of local treatment. The reason for the doubt lies in the lack of neurological training in many gynæcologists, who have mistakenly treated such diseases as hysteria, neuralgia, lateral sclerosis, and locomotor ataxia as mere nervous manifestations of pelvic disease. I have elsewhere reported an instance of removal of the ovaries for pains that were due to an aggravated spastic condition; and the physicians that follow my service at the Spruce Street dispensary recently saw an even more ludicrous error of a well-known

colleague: A woman applied for the relief of a pain in the side in the region of the floating ribs, making the statement that she had been under treatment for it at a neighboring dispensary for several years. The treatment had been directed entirely to the pelvic organs, and much pressure had been unsuccessfully brought to bear on her to consent to a removal of the ovaries. In spite of this treatment her pain was somewhat worse. In glancing at her back I was led to request that the corsets be removed, which revealed a most marked case of scoliosis, with corkscrew twist of the vertebræ. A properly fitting brace gave her a complete relief from pain. Even a slight acquaintance with orthopædics would not hurt gynæcologists; an elementary training in neurology is certainly essential to correct diagnoses in this specialty.

Besides errors of diagnosis it is possible that the present tendency to minimize the effect of uterine disease in causing backache and other neuroses is due to the failure to cure such conditions by removing scar-tissue from the cervix. Failing to cure these cases by cutting out this harmless reparative effort of nature and by removal of the appendages, the remainder of the woman is kept in bed for long periods of time under the theory that the rest-cure was the proper thing after all and that rest was the most essential part of the rest-cure.

Clinical proof of the dissipation of these baneful symptoms by the use of means that combat the initial microbic affection and its nutritional and hypertrophic consequences is the best proof of their correlation.

A recent case will, I think, present this proof in a strong light. A healthy young lady fell a short distance from a hammock, striking the end of the spine. She suffered immediate pain, and two weeks later applied to an intelligent gynæcologist, who treated her for retroversion, and later for inflammation of the ovaries, so far as could be ascertained from the patient. After some early relief the condition became stationary. At this time the case was seen in consultation by Dr. Baer, of this city, with a view to removal of the appendages, which was, however, not done for some reason. Sixteen months after the beginning of the disease the patient entered my private sanitarium in the following condition. Subjective symptoms: continuous, deep-seated scratching pain about an inch and a half above each ovary; a tender pain in the sacrum, and an inability to walk more than two squares without an intensification of these symptoms and great prostration. Objective symptoms: external evidences of perfect health, marred only by coldness of the extremities. Internal examination showed considerable leucorrhœa; uterus apparently small and in normal position, but when elevated on the finger in the posterior cul-de-sac extremely painful. Thinking the case one of posterior parametritis or ovaritis, she was treated by the vaginal galvanic method, in conjunction with general electricity and massage for the incipient nervous protration that was becoming manifest. Considerable improvement resulted, but no headway was made with the peculiar pain in the ovarian regions until it was recalled that nothing had been done directly for the endometritis. The sound, now passed for the first time, showed that the apparently small uterus had a cavity exceeding three inches. An intra-uterine positive application was therefore made, of a strength of twenty milliamperes, and this had the happy effect of checking the so-called ovarian pain permanently. Four subsequent applications of the same kind were made for the control of discharge, and the patient was restored to health and has remained well, now for some time.

This patient had been kept for three months on a lounge by her previous attendant under the theory that this supposed essential of what is called the rest-cure would be of service. Shorn of its institutional control and electricity this fashionable mode of treatment is a two-edged sword that is responsible for more than one case of chronic invalidism. Used with such essentials, including direct electrical applications to the uterus in the class under consideration, these cases in the borderland between the domains of gynæcology and neurology may be permanently restored to health, though he who essays but one part of the treatment will meet with frequent failure and disappointment.

For therapeutic purposes, cases of chronic metritis are divisible into two classes that resemble the divisions made by the late George M. Beard in cases of sexual neurasthenia in the male. In the one class the affection occurs as a purely local disease, the nervous organization of the individual being so robust that it fails to become affected by the local disturbance; in the other class a far less degree of local trouble may be found associated with profound depression and disorder of the nervous system— a disorder that seems greatly disproportioned to the local disease.

The treatment of the first class of cases is naturally entirely local, and may generally

be carried out in the office, when the disease has not yet ascended to the tubes and ovaries. Various modes of treatment have been efficaciously employed, though many are now abandoned as either ineffective or dangerous. I shall limit my remarks to the local use of electricity, first prominently brought forward by Apostoli, whose conclusions have been more than confirmed by my own experience. As in other subacute microbic affections of the glandular membranes, the galvanic current presents a typical alterative action which may be brought to bear directly upon the diseased surface, and by means of applicators that are in themselves innocuous because elastic, easily inserted, and lacking the dangerous piston action of the cotton swab. The contrast with acids or other cauterants that must be inserted by force is very great; no hooking or pulling on the cervix or other harsh methods are necessary, and the local action is, moreover, strictly measurable and controllable. By reason of its greater antiseptic effect the positive pole is usually preferable, though in the later stages of the disease, when the endometritis has eventuated in a hyperplasia, the galvanic alternative method is better than the use of a single active pole. In subinvolution, particularly, the alternative galvanic method within the uterus is quickly curative, accompanied at each treatment by a primary faradic application.

Judging from results, the local electrical treatment seems to act in a threefold manner, each special element of the method varying in usefulness in different cases. One part of the action is a local alterative effect on the endometrium; another results in a quickened absorption of hyperplastic tissue, and still another in stimulation of the muscular fibres to immediate contraction and increased tone. The first action is most important in fungous and hæmorrhagic cases; hence, the positive pole should be used alone, with a duration of some minutes at each application. As the possibility of causing an immediate increase of muscular tone in the uterus increases, the alternative method becomes more valuable; and in recent subinvolution the faradic current alone is usually sufficient.

If at the initial examination of a case, a reasonable doubt is present as to the preponderance at that time of the original metritic trouble, or of a secondary extension into the tubes and ovaries, the intra-uterine method should be proceeded by a more or less prolonged vagino-abdominal galvanic treatment; and in these cases, as well as in the second class here described in which the nervous system is affected, the value of institutional treatment is enormous. By a combination of internal and external electrical treatment, massage, diet, and partial rest, these cases can be almost invariably restored to health, unless pus-cavities are formed—an event that is rarer than some would have us believe. It may take weeks to accomplish these results, it is true; but it is also true that it takes years for the patient to recover health after the performance of a castrating operation.—*For discussion, see Society Reports.*

SUCCESSFUL TREATMENT OF MEMBRANOUS CROUP WITHOUT EITHER TRACHEOTOMY OR INTUBATION.*

By JOHN B. TURNER, M. D.

The class of cases to which I refer are of laryngitis with fibrinous exudation and not complicated by diphtheria. My experience before February, 1891, covering a period of nine years, was to have treated medicinally eight cases, six of which died, showing a mortality of 75 per cent.

The results of tracheotomy in the practice of my medical friends having been so unpromising (all the patients dying), I did not at any time see fit to have the same tried in my practice. As to intubation, my experience is small—two cases, both dying. I condemn tracheotomy and intubation in true croup, as the same objections obtain in both, viz., that the accumulation of muco-pus in the lower part of the trachea and in the bronchi is lost sight of. Paralysis of the posterior crico-arytenoid muscles, preventing dilation of the glottis in inspiration, is a symptom no doubt relieved by tracheotomy and intubation, but the other paramount elements of danger in the case, as pneumonia, capillary bronchitis, accumulation of muco-pus, feeble expiratory efforts preventing expectoration, due to general debility and exhaustion, are *unremedied.*

The treatment I have used since February, 1891, is based upon the allaying of inflammation about the site of the membrane, effecting the separation of the membrane, lessening the formation of new membrane, effectually controlling laryngeal spasm and sustaining the strength. I use asafœtida by suppositories to allay spasm and to give needed intervals of quiet, restful sleep, and consider it a valuable and much overlooked remedy in membranous croup.

For the other conditions or symptoms I used ammonium chloride given in syrupy

*Read before the Philadelphia County Medical Society, February 10, 1892.

mixture without water, as the addition of water makes it unpalatable to children.

In Wood's *Reference Handbook*, in an article written by Dr. Nickles, of Cincinnati, "Wibmer found a very decided increase of the bronchial mucus after hourly doses of eight to fifteen grains of ammonium chloride and other careful observers noticed the same effect. Experiments of Rossbach seem to show a different mode of action. Under the influence of the salt, the tracheal mucous membrane became anæmic and the secretion of mucus gradually ceased. The utility of ammonium chloride in catarrh of the air-passages may therefore depend upon a favorable modification of the vascularity of the mucous membrane, not merely upon a change of the quantity of the secretion." I am of the opinion that Rossbach's view is the more probable one regarding the action of ammonium chloride, and will better explain its beneficial action upon the catarrh accompanying croup.

I will now give the details of the treatment pursued in my last four cases, and advocate it as one simple, humane, and easily applied.

Case 1. On February 16, 1891, I was called to see Sallie B——, aged eleven months, who was suffering from a severe attack of membranous croup. The mother had lost two children on former occasions by the same disease, one in twenty-four and the other in thirty-six hours. Why croup has a predilection for certain families, I am at a loss to know.

I had the child taken to the Children's Hospital, and Dr. Samuel Ashhurst confirmed the diagnosis and recommended tracheotomy, which was refused by the mother. When the child was brought from the hospital to her home I gave the following treatment:

℞ Ammonii chlorid.....3j
Syr. tolutan .....f℥ij M
S. Half a teaspoonful every two hours.

℞ Asafœtidæ pulv.....gr. xvi
Quininæ sulph.....gr. iv
Codeinæ.....gr. ½
Olei theobromæ .....gr. cxxx M
Fiat suppos. no. viii
S. One every four hours.

The child did well (the attack lasting eleven days) and recovered. The patient received whiskey and milk at regular intervals, and was kept in a well-ventilated room. By this treatment the appetite remained fairly good, and the strength was sustained. The same child had another attack on December 18, 1891, and by the same treatment was restored to health. I call this second attack Case 2.

Case 3. John D——, aged eighteen months; attacked on August 26th. Same treatment, and child recovered on the eighth day. The mother poulticed this boy on chest and over trachea, of which action I approved.

Case 4. Harry J——, aged two and a half years; attacked March 6th. Disease lasted one week. Recovered by means of same treatment. This case received larger doses of the ammonium chloride mixture because of his being older than the other children.

There was no atomization used on these cases. *For discussion, see Society Reports.*

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Society Meeting, Feb. 10th, 1892.

Dr. John B. Roberts read a paper on "A Case of Malignant Disease of the Stomach in which Gastro-enterostomy was considered." (p. 405.)

Dr. J. M. Baldy read a communication on "Chronic Endometritis." (p. 406.)

DISCUSSION.

Dr. John C. DaCosta: I think that cases of pure acute endometritis are rarely seen. The cases that I generally meet with are chronic cases in which there is metritis in combination with endometritis and hyperplasia of the uterus. The treatment of acute endometritis should be as different from that of the chronic cases as that between an acute inflammation of the eye or legs and a chronic inflammation of them. In the acute as well as the chronic form injections are of much value. The reason that injections often do not benefit is that they are not properly given; they should not be given with the woman in the incumbent position, in such a way that the water will reach the neck of the womb and distend the vagina, opening out the folds in the anterior walls and washing away the poisonous discharge. In order to do this the patient should be instructed to keep the vulva closed with the fingers of the left hand until the vagina is filled and distended, and then allow the water to escape. This process can be repeated as often as necessary. In chronic cases nothing will do more good than a good free bleeding. Three

to five ounces of blood should be taken, and the woman will often get up off the table with all the pain gone. Another good plan of treatment is by the thermo-cautery burning a hole one-quarter of an inch deep into the cervix. Ten days after such an application the uterus should look entirely different. Dr. Baldy's method of treatment by dilatation and curetting in these chronic cases is one I have used for years, and is of value; for these uteri often have diseased membrane and fungus granulations, keeping up a continual irritation, which the scraping will relieve by removing a cause of irritation and setting up an acute inflammation instead of the chronic one. I should rather hesitate to follow Dr. Baldy's plan of injecting tincture of iodine in the uterus. I think a safer way is to take piece of cotton in the dressing forceps and swab the whole surface with the preparation of iodine. If your use such a preparation as I do, twice as strong as Churchill's tincture of iodine, you will find that there is very little hæmorrhage. The preparation which I use is one part iodine, two parts iodide of potassium, and four parts of gylcerine. This will cause a decided contraction of the uterus; if it does not, give ergot in doses of teaspoonful every hour until the bleeding stops. I do not like the idea of tamponing the uterus. I do not think that is necessary; it is better to stop the bleeding before the patient is left.

Dr. Charles P. Noble: Dr. Baldy's paper discusses a very important subject, and one upon which every practitioner of experience has decided views. Concerning numer special statements in the paper, there is a general concurrence among gynæcologists; but in my judgment the general teaching of the paper is not sound, and if allowed to go to the general practitioner for his guidance, I feel certain that evil results will follow.

It seems to me that Dr. Baldy has gone back ten years to the point where gynæcology was when I was a student; and not only are we led backward, but are given no reason therefor. A word with reference to pathology: A mere discharge from the uterus does not indicate endometritis. We are indebted to Dr. Emmet and others for disapproving the idea that every uterine discharge indicated endometritis. This may come from various constitutional derangements, such as a feeble heart, general debility, phthisis, constipation, or a sluggish portal circulation, and if these are remedied the discharge will disappear. This class of cases must be eliminated strictly when discussing endometritis. Some even go so far as to deny that there is such a disease as endometritis. I have not studied the endometrium microscopically; but, clinically, I believe that there is endometritis. Another important point in the study of endometritis from the therapeutic standpoint is whether the disease is or is not complicated. Treatment which is beneficial in uncomplicated endometritis may be and is dangerous where complications exist. Endometritis is often the forerunner of salpingitis, which is the forerunner of peritonitis. Old chronic peritonitis cases generally have endometritis. We also know that cases of uterine fibroid often have endometritis. It is apparent that the treatment of such cases should be essentially different from the treatment of uncomplicated endometritis. When the endometritis is uncomplicated, I think that treatment directed to the uterus is moderately safe, although even here we may produce complications from intra-uterine applications, and especially from intra-uterine injections. The experience of our predecessors has proved this, and has shown that most cases of endometritis can be cured without treating the endometrium directly. I have supposed that we had heard the last of intra-uterine injections. In the hands of our teachers the practice was found dangerous and was given up. When the cervix is dilated widely, as after curetting, the danger is probably slight; but when done in the office without such dilatation it is distinctly dangerous—how much so any old book on gynæcology will prove.

I regret that the limited time allowed for debate will not permit me to discuss the subject further; but it seems to me that the points presented are very vital ones, and that they have been neglected by Dr. Baldy.

Dr. M. Price: I thank God that I am not a woman, if a woman is to be treated in this way. The question has often been asked, Why is it that we have so much pelvic trouble? I say that the paper to-night answers that question. Every sort of acid and application has been forced into the uterus. It has been burned by the hot iron. It is no wonder that we have endometritis. Why should we not have endometritis with complications extending to the other organs and to the pelvis, requiring removal of the diseased tissues? The same men that advocate this treatment admit that they have had to remove the appendages a few weeks after dilatation.

Dr. Baldy: The treatment which is so vigorously denounced referred simply to uncomplicated endometritis, not to endometritis associated with fibroid tumor or pus tubes, or

any other serious pelvic or abdominal disease. I should treat these troubles as the occasion called for. Where endometritis is uncomplicated, it can be dealt with without the slightest possible bad effect. My cases are put to bed, and kept there until safe from all inflammatory trouble. Intra-uterine injections can be made in one's office with impunity if done carefully. The cervical canal in some of these cases is so patulous that it would admit a tube twice the diameter of the nozzle of the syringe. I use the syringe almost daily, and have not seen the slightest trouble from it.

Dr. DaCosta spoke of scarifying and curetting to produce bleeding. The curette in my hands generally produces that effect. If the bleeding is moderate I do not use ergot. When I use ergot, I give it in fair doses to produce contraction of the uterus. I select the cases which I subject to the treatment described, and I care not if I have gone back ten or twenty years if the treatment brings about the desired results safely. I am continually receiving patients on whom abdominal section has been done, in whom the uterus is large and heavy, and all the old symptoms remain. I scrape the uterus and remove a large quantity of *débris* from some, and in many this gives relief.

Dr. John B. Turner then read a paper on the "Successful Treatment of Membranous Croup without either Tracheotomy or Intubation." (p. 412.)

Dr. Edwin Roenthal: It seems to me extremely strange that such a disease as membranous croup should be so easily remedied by muriate of ammonium and asafœtida suppositories. In a series of some four hundred and twenty odd cases which I have followed and studied, in my own practice and in the practice of my friends, which were not treated by intubation or tracheotomy, and in which the diagnosis is undoubted, but three recovered. In sixty-four cases that I have intubated, fully one-half died. Many of these cases had been previously treated by muriate of ammonium and also by chloral, which I consider a better antispasmodic than asafœtida. Chloride of ammonia has been long used in this disease. It was recommended by Dr. Condie—one of our earliest members—for membranous laryngitis, and in *Watson's Practice of Physic*, edited by Condie, was described the method of its action, which, if I remember correctly, was to defibrinate the blood, prevent the pseudo-membrane from forming, and facilitate the absorption of tissues already formed. If Dr. Turner considers membranous croup one disease and diphtheria of the larynx another disease, he falls into error regarding treatment. If he means to say pneumonia, capillary bronchitis and œdema of the lungs, which are so often complications of croup, succumb so easily to the treatment by muriate of ammonia, or that they will not occur when cases are treated in this way, I think this places him also in error. I have seen so many fatal cases of croup that I cannot believe that true membranous laryngitis can be successfully treated in the manner he describes. I have practiced intubation over one hundred times, and have had fairly good success. But I have not relied upon remedial measures such as have been mentioned.

Dr. M. O'Hara: The easy cure of cases supposed to need tracheotomy can bear a a very different explanation. It may well be in view of the many cases of recovery after the apparent judicial condemnation of the doctor, not depending sufficiently upon the powers of Nature.

Some years ago I reported a case and published it in the *Proceedings* of the County Medical Society, which can be referred to for details (vol. i. p. 21), entitled "Remarks on a Case in which the Necessity for Tracheotomy was Averted by the Systematic Action of Intense Cold exciting Forcible Inspiration." This was a case in which a most eminent throat specialist considered the time gone by for success by tracheotomy, in a case of nasal diphtheria after measles, and considered it would be closed by death in eight hours, and yet recovery under use of ice, and he frankly told the mother afterward that he probably would have finished the case with the knife. Here there was an error of judgment; though all thought there was membranous deposit, there could not have been any. I have known similar cases, and sending for a consultant surgeon in several cases, waiting brought the patient around. The late Dr. Henry A. Smith related at one of our meetings many cases of this kind in a discussion on the topic, and I hope those of us present familiar with the point will relate such cases for instruction. I rise to have this point specially ventilated.

Dr. H. R. Wharton: I agree with Dr. Turner that many cases of croup get well with the simple medicinal treatment, but I disagree with him in regard to the large number of unsuccessful results from tracheotomy and intubation. My experience with tracheotomy is that even in the most urgent cases, many recover. Last year, at the Children's Hospital, 43 per cent. of the tracheotomies recovered. I have used

chloride of ammonia to some extent in the treatment of croup, but in the last few years I have put more confidence in the carbonate of ammonia, and follow the plan of treatment suggested by Mr. Parker, an English surgeon. I combine the carbonate of ammonia with syrup of senega. My routine treatment in ordinary cases of croup, in which the symptoms are not sufficiently urgent to call for intubation or tracheotomy, is to place the patient on carbonate of ammonia with senega and to see that he is thoroughly stimulated. At the same time I believe that local treatment by inhalation of some medicated vapor is of service. I have recently employed the ordinary steam atomizer, in which I use an alkaline solution such as carbonate of soda and glycerine. The atomized solution is used as frequently as every half-hour or hour, according to the urgency of the symptoms. This solution is also useful after intubation or tracheotomy. I believe that many cases of croup do get well if carefully treated and do not come to the point where operation is necessary I think that the use of strychnine and digitalis in the early stages of the disease often prevents trouble later on from cardiac failure. While at times these very urgent cases will get better without operation, yet in my experience this is the exception. Within a year and a half, death has occurred in five cases of croup in which I was summoned to do intubation or tracheotomy, before I could reach the patient. I think it unwise to say that in these urgent cases operation should be postponed, for many cases of croup die suddenly.

Dr. B. Trautman: We should not lose sight of the distinction between catarrhal croup and membranous croup. Most cases of catarrhal croup will get well without much treatment. By keeping the patient warm and giving an emetic, the cure will be effected. In membranous croup the tendency is to postpone operation too long, till cyanosis sets in, and then the patient generally succumbs. The course of treatment which I pursue in membranous croup is the administration in one mixture of bichloride of mercury, tincture of iron, and chlorate of potassium. As an emetic I give sulphate of copper, one grain for each year of the child's age. That will often bring away the whole membrane. If it does not bring it away, tracheotomy or intubation should be done at once.

Dr. Nutt, of Williamsport: This subject has interested me very much. For the last eight or ten years I have done intubation frequently—I think in seventeen consecutive cases—and out of that number there have been only four deaths. I am therefore a strong believer in intubation, and I had hoped that there would have been a more general discussion on this point. I fully agree as to the necessity for intubating early. When I first began the use of this measure, I usually put it off until the last moment, as a last resort. When the lungs are all filled up and the child cyanotic, I do not believe anything will save the child. I cannot see that intubation has any bad effect, and if used early in the disease we can reduce the rate of mortality very greatly.

Dr. John B. Roberts: It seems to me that this is the old story, that the man who never operates is sometimes wrong, and the man who always operates is sometimes wrong. The discussion seems to be a little uncertain because some speakers use the word croup and others the word diphtheria. Whether or not they mean the same thing, I do not know. If I am called in surgical consultation to a child with difficult respiration due to some inflammatory disease of the throat, it makes little difference to me whether some pathologists call it croup and some diphtheria. I call them all diphtheria, and advise the attending physician to report the case as diphtheria to the Board of Health. Eight or ten years ago I made up my mind that in all cases of diphtheria where there was dangerous difficulty in respiration, my duty was advise tracheotomy, and to do it. That was before the time of intubation. I did tracheotomy over and over again, and though I never saved a patient, the relief of the patient was so great that I never regretted the operation. I believed that in all such cases, where there was dangerous cyanosis, my duty was to open the trachea. Since intubation has been revived by Dr. O'Dwyer, I have adopted that as the primary operation and reserve tracheotomy for a later procedure. To see a child suffocating to death and withhold your hand, is almost as bad as saying that you will not use the stomach-pump even though you know that the person has poison in the stomach. Of course, I do not advocate intubation or tracheotomy in cases where the child is dying from the diphtheritic poison and not from obstruction in the larynx. A few weeks ago I was called in consultation to see a child. The case had previously been seen in consultation by another gentleman, who said that nothing could be done. I was called and introduced an intubation-tube, and in a few minutes the child was breathing comfortably. The tube was vomited out, however, but the relief which he had experi-

enced was so great that the child permitted me to apply the tube again without struggling. He subsequently wore the tube about two days, and is now well. We must select our cases for tracheotomy or any other operation.

Dr. John C. DaCosta: It is not strange that such brilliant surgeons as the last speaker advocate tracheotomy. But what is the mortality? Some ten or more years ago I collected and analyzed twenty-four or twenty-five hundred cases of tracheotomy, and the result showed that only about 24 per cent. recovered. But one reference has been made to-night to the old-fashioned method of using emetics. Nothing will dislodge the membrane quicker in croup than an emetic. You may use ipecac or sulphate of copper, but one of the best is the yellow sulphate of mercury, which latter, I think, has more than a simple mechanical effect. In true croup there is nothing equal to the internal administration of mercury, which may be given in the form of the mild chloride, or of the bichloride or the old-fashioned blue pill. Another point is the enforcement of sustaining treatment. If quinine is used in suppositories, it should be in the form of the bimuriate or bisulphate, or the sulphate mixed with tartaric acid, so as to insure its being dissolved. Anodynes may be needed to quiet spasm.

Dr. John B. Deaver: As has already been said, each case has to be treated on its own merits. There is much to be accomplished both by tracheotomy and by intubation in cases of true croup. My experience, however, has been that in many cases the introduction of an intubation-tube occludes the larynx still further and increases the child's suffering; in those cases I do tracheotomy. I think that these operations are better applicable to cases of croup proper, and I am not in favor of doing them where there is much depression, as occurs in true diphtheria. I cannot agree that all cases of croup die an easy death even when the tube is employed. I have seen them strangle as much after intubation or tracheotomy as before. The operation usually does give relief, but the inflammatory process may extend further down, and the symptoms of obstruction may renewed. I believe strongly in the use of mercury in these cases in order to get its constitutional effect. The bichloride acts quicker, but it is more apt to irritate the gastro-intestinal tract. I believe that there is a difference between croup and diphtheria. I do not believe that they are one and the same disease. The one is local and the other is constitutional. This subject is a very interesting one, but I do not see how we are to instill into the minds of any of the cases which should be intubated and those in which tracheotomy should be done. This question must be judged by the experience of the operator.

Dr. W. S. Stewart: The Doctor did not make a distinction between the true membranous croup and what is known as spasmodic. The latter can be relieved by emetics and counter-irritants, but in true membranous croup we need something more than emetics. I agree in regard to the use of the remedies to which reference has been made. I believe in calomel, or mercury in other forms. I have been to many operations for tracheotomy, and have seen some cases when the operation was performed, where I believe I should have still hoped for recovery without an operation. It is hardly fair to record such cases of recovery as a result of the tracheotomy. On one occasion I went three times to one case to assist in performing tracheotomy, and every time we were refused the privilege. Death was confidently prophesied by the attending physician, but the child recovered.

On another occasion I was attending a child where I feared death was going to result, and I advised the family to call in consultation a gentleman who intubated. During the interval of sending for a doctor and his arrival the child improved; still, I asked the doctor if it was a good case. He said he regarded it as a good case for intubation. I told him to put in the tube, and turned the case over to him. On the second day the child was dead. I do not say that we should never operate or never use a tube, but I do say that those who are enthusiastic in regard to operations are often careless in their zeal to press the proper treatment. They do not pursue the medical treatment as perseveringly as they should.

Muriate of ammonia by itself is very hard on the stomachs of children, but a good combination is chloride of ammonium with chlorate of potassium and syrup of senega. I often combine with this, syrup of squills, ipecac, and tolu; I also administer quinine by the mouth in the form of the tannate. This method often has a very good effect in arresting the development of ordinary membranous croup, when given in large and frequent doses, and the expectorant has the effect of absorbing the membrane already formed.

Dr. G. Betton Massey: There is a therapeutic item to which I have often wanted to direct the attention of general practitioners. During the ten years that I

spent in general practice, I invariably prescribed insufflation of powdered sulphite of sodium in those cases of diphtheritic sore-throat with general systemic disturbance that seemed to be the first stage of diphtheria. In all these cases the membrane disappeared in from twelve to twenty-four hours, and it was a curious fact that in these ten years I did not see a bad case of diphtheria. Whether these membranous sore-throats were of that nature, and were arrested, I am of course uncertain. The powder was insufflated through a paper roll every half-hour, the paper being burnt after each insufflation to prevent the wrong end being subsequently used and infecting the nurse.

Dr. Daniel Longaker: The theory which best fits the facts in these cases is that most of these cases are diphtheria, and that we have either a primary laryngeal diphtheria or a secondary laryngeal diphtheria. It often happens that a child is taken with membranous laryngitis and two or three days later the membrane will appear in the fauces. Diphtheria is primarily a local disease, with, later, general manifestations. It seems to me that the local disease in the fauces is the point of invasion, and a poison is developed and absorbed with such serious effects. I do not think that any one method of treatment of croup can be maintained. Every case must be treated on its own merits. I have found the peroxide of hydrogen very efficient when used as a swab or as an atomized solution. I have used it in a number of cases in the past three or four months with satisfactory results. I do not advocate exclusive medicinal treatment, or exclusive treatment by intubation, or exclusive treatment by tracheotomy. Each method has its own field of application.

Dr. Rosenthal: I have used the peroxide of hydrogen for over a year. Of the kinds obtained in the markets—manufactured by Charles Marchand, Rosengarten & Sons, and Merk—I find that of Merk is the best. At first I used it diluted, but gradually increased my strength of solution until now I use it absolutely pure. I apply it in membranous laryngitis in the form of a spray by means of an atomizer quite copiously, and when the membranes are visible the applications are made direct with probangs of cotton; my applications are made hourly. My remedial treatment is essentially antiseptic, mercury being used fearlessly. I also use stimulation freely—as, for instance, in a child of four years I gave as much as a gill of brandy during twenty-four hours. I firmly believe that my success in the treatment of diphtheria, whether it be of the larynx or fauces of the nose, is based on this antiseptic treatment; and in peroxide of hydrogen I think we have a most potent means of applying it. I attribute my success to it, for I believe, while diphtheria is a constitutional disease, the presence of the membrane hastens the absorption of the poisons and produces septicæmia and toxæmia; and in the peroxide of hydrogen we have a cleansing agent which quickly modifies, removes, or alters these conditions of things. In the last epidemic I have treated all forms except of the larynx, with but one death, and that one was in a rhachitic child. There is one point that I wish to place myself on record as against, and that is the indiscriminate use of emetics in membranous laryngitis; I believe it is wrong in theory, wrong in practice, death is hastened by their use, and I have yet to see one case benefited by their use. I believe that diphtheria and croup are clinically the same whether the disease begins primarily in the larynx and extends upward, or in the pharynx and progresses downward. The youngest case intubated by me was four months and twenty-seven days, the oldest five years and six months; in all my cases peroxide of hydrogen being freely used,

Dr. DaCosta: I understood that the discussion was on croup, and not on diphtheria. The mode of onset, the symptoms, and the results of the two diseases are entirely different. Take a few points of differential diagnosis.

In croup the attack is more sudden, and the patient recovers more rapidly. In diphtheria the patient does not recover fully for weeks, and the attack is apt to be followed by paralysis, which we do not find in croup.

Diphtheria is contagious; croup is not. Croup is found in isolated cases; diphtheria attacks whole families.

Dr. DeForest Willard: While there are such wide differences of opinion in regard to the pathology of these diseases, it is not strange that there should be these marked differences as to the methods of treatment. Some of the speakers, perhaps, refer to one disease, while others refer to another. We all recognize that mild cases get well without much treatment, but there is another grade of cases which will die, whether treated medically, or by intubation, or by tracheotomy. Reliable inferences cannot be drawn from a small number of cases, and even in a larger numbers we may all know that we may have a hundred successive case of recovery in a certain disease, while all of the

next ten may die. This is especially true in membranous croup and diphtheria. I am confident that I have saved a good many lives by tracheotomy, but I have also lost many. Yet the comfort secured to the patient has amply repaid me, even though death has subsequently taken place.

DR. TURNER: I was led to write this paper from the fact that I knew that certain cases of spasmodic laryngitis were intubated and reported as cases of recovery from croup. The treatment which I have mentioned will decide the question whether the case is one of spasmodic croup or not. I also employ calomel, and use quinine in the form of the bisulphate in suppositories. It takes the membrane three or four days to be separated. It cannot always be removed by an emetic, but if you get rid of the spasm you give a great deal of relief. Asafœtida has not been used before in croup. I do not say that intubation and tracheotomy are of no use, but where the membrane is below the trachea and in the bronchial tubes, the case cannot be relieved by these measures. The treatment which I advocate gives the child sleep, rest, and nourishment. Take a healthy child and treat it with emetics and other things which have been mentioned, rousing it up every hour to spray its throat, it would take a good constitution to stand that. Croup is not a very common disease. And in my paper I have referred not to diphtheritic croup, but to membranous croup.

In regard to the employment of calomel, I will state that I employ a purgative dose in the beginning of the treatment, if constipation exists, to arouse secretions, and do not use it for its supposed action to dissolve the membrane.

TREATMENT OF CATARRHAL FEVER.

Dr. V. Lockhart writes in the *Atlanta Med. Surg. Jour.* that this disease embraces two stages, the dry and the moist, and the indications for treatment are somewhat different in each.

To relieve the fever and coryza of the first stage antifebrin is a good remedy. It may be combined with quinine,

℞ Antifebrin.....gr. viij—x
Quinine.....gr. v.

M. This will generally insure rest and a moist skin.

A purgative,

℞ Hydrarg. chlor. mitis.....gr. v.
Ipecac.....gr. j.
Rhei. pulv.....gr. viij.

M. One dose, to be followed by a dose of Epsom salts or castor oil if needed.

Order a bowl of hot water, add a few drops oil of turpentine; let the patient inhale the vapor, a shawl or blanket thrown over the head to confine the steam. This often affords much relief. If the throat be sore, apply turpentine to the fauces with a swab.

After the purgative has acted give,

℞ Tinct. aconiti rad.....5j.
Vini antimonii.....5ijss.
Spt. ether. nitros.....5vj.
Liquor ammon. acetatis.....q. s. ad. 5jv.

One-half teaspoon- to teaspoonful every two to four hours as indicated. Children four to five years of age twenty drops. Opiates are not good for this stage, but if there is much restlessness, a dose of Dover's powder may be given. Antikamnia is better. Mustard should be used as a counter-irritant. One part of ground mustard to two of flour. It should be applied frequently during the disease, and when the mustard is not on, a poultice of wheat bran or cloths wrung out of warm water, and over it a layer of oiled silk. Quinine in moderate doses three times a day. The temperature of the room should be kept pleasant. Under this treatment the cough will become loose, fever will subside, and dyspnœa and soreness of the chest cease in a day or two. Then give,

℞ Syrup scillæ,
Syrup senagæ,
Syrup tolut.
Tinct. opii. camphorat.....aa 5j.
Ammonii chloride.....5ij.

M. Sig.—Teaspoonful every three or four hours. Digitalis comes in well, and it may be added to the syrup as indicated.

In small children prompt and efficient measures are often needed to relieve the dyspnœa and other threatening symptoms. Give fluid extract ipecac in doses sufficient to insure free emesis. This may be necessary at intervals for several days, but it must not be given so as to keep the child nauseated, as this interferes with the measures of support, which are important, especially if the child has pertussis. In this disease we must support the strength by using stimulants and rich, nourishing food, and they are indicated early. Besides the usual treatment indicated above, the following is a good prescription for *whooping-cough:*

℞ Ext. cannabis indicæ.....gr. xv.
Ext. belladonnæ.....gr. viij.
Alcohol
Glycerine.....ad 5jss.

M. Sig.—Four or five drops to a child one year old; one of two years old, five to eight drops three or four times a day.

SELECTED FORMULÆ.

PASTE FOR PRURIGINOUS SQUAMOUS ECZEMA.

In the treatment of this affection, C. C. Vanderbeck has obtained excellent results from the local use of the following paste:

℞ Oxide of zinc.....grammes 9.60.
Gelatine,
Glycerine.....āā " 15.00.
Water..... " 25.00.
M. Sig. Apply and cover with thin linen.

—Journal de Médecine de Paris, January 31, 1892.

SOLUTION OF ERGOTINE FOR HYPODERMIC INJECTION.

The following solution, according to Biedert, is an excellent one, as it lacks irritant properties and is not easily decomposed:

℞ Ergotine.....gramme 1.
Distilled water.....grammes 5.
Crystallized phenic acid..... " 0.01.
M. Sig. For hypodermatic injections.

—Journal de Médecine de Paris, January 31, 1892.

TREATMENT OF PITYRIASIS VERSICOLOR.

In the treatment of this disease, Besnier recommends a medicament that will first produce desquamation and afterwards a cutaneous irritation. He advises: (1) Frictions, morning and night, with black soap, or better, with pumice soap; (2) the substitution of these measures by the application of the following ointment:

℞ Precipitated sulphur.....grammes 10.
Vaseline..... " 90.

—Le Bulletin Médical, January 31, 1892.

OINTMENT FOR MARGINAL EXFOLIATIVE GLOSSITIS.

Besnier recommends the following:

℞ Chlorhydrate of cocaine.....gramme 0·05.
Balsam of Peru,
Boracic acid.....āā " 1.00.
Vaseline.....grammes 40.00.
M. Sig. For local application twice a day.

—Le Bulletin Médical, January 31, 1892.

ANTIASTHMATIC SOLUTION.

The following prescription is recommended by Huchard in the treatment of asthma:

℞ Iodide of potassium,
Tincture of lobelia,
Tincture of polygala,.....āā grammes 10.
Extract of opium..... " 0.10.
Water..... " 900.
M. Sig. A teaspoonful, night and morning, in a little water. The addition of opium increases the tolerance for the iodide. The potassium salt can be replaced by the sodium iodide.

—Le Bulletin Médical, January 31, 1892.

CARDIAC DILATATION.

For cardiac dilatation, with slight congestion of the lungs, due to rheumatism, in a man, 37 years, Prof. Da Costa gave the following treatment (*Col. and Clin. Rec.*):

℞ Tinct. digitalis.....gtt. x.
Tinct. capsici.....gtt. j.
Tinct. cardamom.....ʒ j.
M. Sig. Three times a day.

And two or three times a week give calomel, gr. j. in the evening, followed by a saline cathartic in the morning. The diet is to be chiefly of meat, with the use of a moderate amount of alcoholic liquors.

PRURITIS VULVÆ.

The wash described below has been useful to many of Dr. Bullock's patients, who have suffered from pruritus vulvæ:

℞ Aluminii nitras.....gr. xxiv.
Aquæ.....ʒ iv.
M. Sig. Wash the parts once or twice a day and use as a vaginal injection in the same way.

—N. E. Med. Monthly.

ACUTE TONSILLITIS.

Dr. M. A. Martin (*Lo Sperimentale*, No. 21, 1891) speaks highly of the following:

℞ Acid carbolic, } .....āā gramme 1.
Camphoræ, }
Glycerin, } .....āā grammes 50.
Aq. destillat., }
Three or four applications a day.

ABORTIVE TREATMENT OF CORYZA.

For the aborting of an acute coryza in the early stages, Capitan recommends the insufflation of the following powder into each nostril:

℞ Salol.....gr. xv.
Acid. salicylic.....gr. iii.
Acid. tannic.....gr. ii.
Acid. boric. (pulv.).....ʒ i.

The treatment should not be continued for more than half a day, as the carbolic acid set free from the salol will injure the nose. After this powder is employed one composed of powdered talc and boric acid may be employed, or the following may be used in place of any of those given, and is equally satisfactory and more safe:

℞ Pulv. talc.....gr. lxxv.
Antipyrin.....gr. xv.
Acid. boric. (pulv.).....gr. xxx.
Acid. salicylic.....gr. iv.

A pinch of this may be frequently used without the disagreeable symptoms caused by the first prescription given.—*La Médecine Moderne, November 12, 1891.*

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO. (Incorporated)
PROPRIETOR AND PUBLISHER.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.)

CHARLES K. MOUNT, Advertising Manager.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates),..... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts,.....$1.50 each.
Bovine Points or Quills,..... 1.00 a doz.
Humanized Crusts,..... 1.00 small.
Humanized Crusts,..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

☞Please accompany orders with the money, and address all communications to

LEADING ARTICLE.

SHALL THE UTERINE ADNEXA BE REMOVED TO PREVENT PREGNANCY? A QUESTION OF ETHICS.

In the progress of abdominal surgery the operation for the removal of the uterine appendages has been so perfected that in the hands of a competent surgeon it is practically without danger, unless these organs contain pus or other septic fluid. This fact is now generally known by the laity. It is also known that women who have had their Fallopian tubes and ovaries removed do not bear children, notwithstanding that in a vast majority of instances the sexual appetite remains unimpaired. Hence, the question has arisen as to whether the removal of the uterine appendages shall be practised for the sole purpose of preventing pregnancy.

There can be no question that pregnancy is not desired by many women, that this feeling is becoming more general with the progress of civilization, and that measures for the prevention of conception will become more eagerly sought. The grave risks to health and life that women run to avoid having children, by procuring abortion, whether this be merely to avoid the trouble and expense of rearing their offspring, or to prevent disgrace, is sufficient evidence of the drift of this matter at the present time.

These facts have led thinking men to wonder how long it will be until it will become prevalent for gynæcologists to be asked by women to remove their ovaries for the sole purpose of making pregnancy impossible. In the REPORTER for November 14th, 1891, Dr. Todd states that a woman consulted him for that purpose; similar examples are not only known to us, but also where the operation has been performed, and we have reason to believe that more of this kind of work is done than is commonly thought.

It is time that the profession considered this matter and made known the ethics governing it, so that no one should err through supposed ignorance. There is certainly a

nice point to determine how far an individual shall have the liberty of wilful mutilation—whether women shall not be prevented by law from such an act as suggested. Certainly, in so far as the profession is concerned, the operation for the sole purpose of preventing conception is malpractice, just as certainly as is the operation of abortion.

No operation in surgery has done or is doing more good for suffering humanity than that of the removal of the uterine adnexa for disease. This makes it only the more important for the welfare of sick women, and for the good name of the profession, that the operation shall not be brought into disrepute by employing it for unworthy and unjustifiable purposes. This matter cannot too soon receive serious attention. The fact that oöphorectomy is attended with so little danger to life, that the possibility of conception is permanently removed, and that the sexual appetite and full enjoyment of the congress remains in most cases, seem to render it inevitable that the women who now would seek abortion would not be long in deciding, on the one hand, between the immediate removal of the annexa and, on the other, the anticipated operation or operations of abortion. Moreover, that many who now resort to the comparatively harmless, conventional, though frequently inefficient means to prevent maternity, would prefer the permanent and absolute preventive is beyond question.

THE TREATMENT OF BASEDOW'S DISEASE.

The therapy of Basedow's disease is one of the most difficult and thankless problems which the practising physician of to.day is called upon to solve. While, fortunately, it is an ailment comparatively rarely met with, it is seen with sufficient frequency to cause the practitioner vexation and trouble, so that a glance at the most rational methods of treatment now advanced will at least place in the hands of our readers one more weapon, which they may have the occasion to use against this malady.

It is well known that that the so-called "nervines," as well as those remedies influencing the vaso-motor system, are entirely without avail in this disease. Veratrine, which has been praised so loudly, when given in fractional doses only causes passing lessening of the excitability of the medulla oblongata. Equally inefficacious, as regards permanent effect, is antipyrine. Digitalis, since it increases the blood-pressure, is entirely contra-indicated. More confidence seems to be placed, both at the start and at the height of the disease, in hydrotherapy, especially when associated with electrotherapy. This, at least, gives the most satisfactory results, and seems based on rational grounds, especially when accompanied by an internal treatment with arsenic and the bromides.

The therapy of Basedow's disease, based upon these lines, is described by Dr. Jaccond in the *Revue de clin. et de thérap.*, and has since been laid down in a similar way in a recent issue of the *Lyon Médicale*, and the *Deutsche Med. Wochenschrift*, and from these sources we sum up the treatment as follows:

1. *External therapy.* In cases of normal, as well as increased arterial tension, and, indeed, in most instances, even when a condition of asystolia exists, hydrotherapy is well borne. In sensitive patients, this should begin with tepid shower-baths of short duration, which should be gradually increased in duration and decreased in temperature. In such cases where douches are not well borne, they should be substituted by sponging. In anæmic cases, this treatment should at once be instituted, care being taken, however, that the cervical region is not included in the douche.

Hydrotherapy lessens the nervous excitability and also the quickened action of the heart.

When menstrual disturbances exist, Beni-Barde recommends cold hip-baths, warm or cold foot-baths, and uterine douches. During the course of the hydrotherapy there should be daily applications of the constant current in the course of the vagi nerves and at both sides of the neck. These electrical applications should be of short duration and of gradually increasing strength. Vigouroux

has suggested that the galvanic and faradic current be used alternately, and his method has certainly been crowned with considerable success. In faradization, the positive pole should be placed on the back of the neck, and the negative pole over the region of the carotid artery, the current be continued for ten minutes, then for five minutes longer, the negative pole may be placed over the thyroid gland. In galvanism, the positive pole should be placed over the præcardial region, and the negative pole at the back of the neck.

Hydrotherapy, as well as electro-therapy, must be continued for a period of five or six months at least.

2. *Internal therapy.* According to Jaccond's theory, arsenic and the bromides should be given alternately. Arsenious acid should be given in gradually increasing doses, beginning with, perhaps, 0.002 gramme, and increasing this to 4, 6, or 8 mg. during the course of a week. The following week this treatment is abandoned, and bromide of potassium in 2 to 4 gramme doses is administered, morning and evening, in some alkaline mineral water. The subsequent week arsenic is substituted, and so forth. If asystolia occurs in consequence of a cardio-vascular asthenia, then digitalis is indicated, whether the asystolia be only temporary (acute dilatation of the heart), or permanent (valvular disease, myocardiac schlerosis); of mineral waters, those containing iron generally give the best results.

3. *Hygienic therapy.* This is of great importance, and should never be overlooked. Coffee, tea, and alcohol should be strictly forbidden, as well as the use of tobacco in any form. An avoidance of any severe muscular exertion or nervous shock or strain, and, finally, an almost exclusive diet of milk (one to two quarts a day), except in cases where there is an idiosyncrasy to this diet.

The chronic course of the disease necessitates a long and persistent treatment, the ultimate success of which greatly depends upon the patient's rigid obedience to the physician's orders.

Andrology is a paying specialty.

BOOK REVIEWS.

A MANUAL OF OPERATIVE SURGERY. By Frederick Treves, F. R. C. S., Surgeon to and Lecturer on Anatomy at the London Hospital; Member of the Board of Examiners of the Royal College of Surgeons. 2 vols., 1550 pp. Lea Brothers & Co., Philadelphia.

In the preparation of a work upon Operative Surgery, the writer is embarrassed by the extensive literature upon this subject, and it is only by the exercise of the greatest judgment in the proper selection of operative procedures that a work of practical value can be produced.

Mr. Treves being a practical surgeon, has exercised this power of selection in a wonderful degree, and has produced a work which could only have come from the pen of a surgeon of large operative experience; and for this reason it is certain to hold a high place among works upon this subject. The description of the various operations is concise and clear, and the author often quotes the words of the inventor of the special operations in its description, so that accuracy is insured, and in many cases adds his personal experience in the use of the procedure.

The sections of the work treating of the General Principles of Operative Surgery and of the after-treatment of operative cases, contain so much that is valuable, that it is worthy of the most careful study, and shows that the author is a careful clinical observer who believes that no painstaking care should be spared in the selection of the operation and the preparation of the patient to bring the case to a successful issue.

We are not a little surprised at the author's unqualified condemnation of the use of the *director* in surgical operations, for we have always considered it, when properly used, a most valuable surgical instrument, and we think he might as well condemn the scalpel, for evil has been done by its careless and injudicious use.

The chapters upon excision of scrofulous glands of the neck and plastic surgery contain much of practical value to guide the operator, and are worthy of careful reading. We are glad to see that Mr. Treves does not approve of the use of the Esmarch's elastic bandage in the excision of joints, although we cannot agree with him as to the evil results following its employment in the operation of osteotomy.

Mr. Treves does not think well of the wiring of the fragments in cases of fracture of the patella, but employs a more conservative method of treatment.

It is a satisfaction to see that so high an authority as the author does not consider it necessary to make a free dissection of the axilla in every case of carcinoma of the breast, if the presence of enlarged axillary glands cannot be demonstrated.

We notice that no mention is made of the operative treatment of varicose veins, and operative procedures employed in the treatment of necrosis and caries of bone.

The book as a whole contains so much valuable information of a practical character that we strongly recommend it to those who wish to consult a modern, practical and reliable work upon Operative Surgery.

THE JOHNS HOPKINS HOSPITAL REPORTS. REPORT IN PATHOLOGY I AMŒBIC DYSENTERY. By William T. Councilman, M. D., and Henri A. Laflem, M. D. The Johns Hopkins Press, Baltimore, Md., 1891.

To everyone interested in progressive medicine, and particularly in the advance of pathological light upon the many dark questions which still surround the acute diseases of the intestines and liver, this fresh contribution from Johns Hopkins will be welcome reading. The subject of this communication is one of exceeding interest not only as regards the disease which it considers, but more broadly because of the bearing it has upon the pathological rôle of the amœba.

The subject has been dealt with in a most scholarly manner, and all the literature of the subject has been amply quoted in support of the observations recorded by the authors, so that in this work one may find practically all that is worth reading in connection with amœbic dysentery. The lesions observed have been recorded in a number of very interesting plates, and these add value to the work.

It is impossible to give in a few words the results of the authors' work. Their observations go to prove that there is a distinct form of dysentery dependent upon the presence of amœbæ as the causative pathological factor, characterized by definite lesions differing in kind from those of ordinary dysentery, and differing also from lesions produced by any of the micro-organisms with which we are familiar, and thus the disease is frequently connected with hepatic and pulmonary abscesses.

To all interested in this subject we recommend this scholarly treatise, which contains the best of all our published facts regarding amœbic dysentery, as well as the records of the careful studies performed by the author at the Johns Hopkins University Hospital.

LITERARY NOTES.

SLEEP.

Like the passionate palm that breathes all the odors of day
To the soul of the night,
Like a river that runs and frets on its turbulent way
To the quiet deep,
Like the swallow, weary of cold, that southward gleams
To her land of delight,
So the heart overfull of its sorrow flows over in dreams
Of compassionate sleep.

Ruth Johnston, in March Lippincott's.

—The *Physician and Surgeon* was enlarged and improved, beginning with the January issue.

—If Herodotus may be called the father of history, Lucian, that versatile and somewhat erratic Greek writer of a later day, may, with equal good reason, be called the father of that form of fiction which has been developed into the modern short story. The volume of *Selections from Lucian*, which Harper & Brothers announce as nearly ready for publication, will certainly be heartily welcomed not only by those who love to read good stories, but by all who care to study the art of fiction as practised by its acknowledged masters. The translation of these *Selections* is by Emily James Smith, and the volume will be in every sense an attractive one.

—An Admirable volume entitled "*The Dog in Health and in Disease*," by Dr. Wesley Mills, discusses in detail the history of all the varieties of dogs, their breeding, education, and general management in health, and treatment in disease. The book is adapted for both the veterinarian, to whom the medical care of dogs is usually confided, and the general reader, whose interest may be limited to that involved in the ownership of a single animal. The writer is Professor of Physiology in the Faculty of Veterinary Science of McGill University, Montreal, the author of *Comparative Physiology* and other standard works on allied topics; and is further qualified for his task by the fact that he has, as he states in his preface, "for the greater part of his life studied this noble animal with pleasure and profit to his own nature." The volume contains a large number of illustrations related to the text, and is further embellished by portraits of various dogs of note of many breeds. Published by D. Appleton & Co.

PERISCOPE.

THERAPEUTICS.

A NEW REMEDY FOR RHEUMATISM.

According to the *Lyon Médical*, October 25, 1891, Dr. Betchine, of St. Petersburg, has made special studies in reference to *ephedra vulgaris*, a plant much esteemed by Russian peasants for its anti-rheumatic qualities. The bark and the root the observer found efficacious in acute articular rheumatism with high fever. In chronic rheumatism its most favorable action was merely a slight temporary amelioration. Unless fever is present the drug is not especially useful.

COLCHICINE FOR THE EYE.

Colchicine is recommended by Dr. Darier in certain eye affections, and is administered in pill form, each pill containing $\frac{1}{64}$ grain of the drug, of which from one to two or four, or even six pills, can be taken daily. Care must be taken to instruct patients to reduce the dose as soon as intestinal derangements manifest themselves. Some patients have taken as many as 200 pills without complaining of unfavorable symptoms.—*Medical News.*

ABRIN AND RICIN IN EYE AND OTHER AFFECTIONS.

The numerous points of resemblance in respect of the physiological action between abrin, the poisonous albumose to which the inflammatory action of preparations of jequirity seeds upon the eye is attributed, and ricin, the albumose of castor oil seeds, has, we learn on the authority of our contemporary the *Pharmaceutical Journal*, suggested the probability of their being identical. Both possess the property of coagulating the blood in a peculiar manner, giving rise to numerous thromboses, especially in the intestinal vessels; they also affect very similarly the mucous membrane of the eye, and they are both converted into non-poisonous substances by digestive ferments. Ehrlich's experiments, however, show that they are perfectly distinct alkaloids. One peculiar action of abrin is to cause the loss of hair speading round the point of injection. In its toxic properties ricin is found to be nearly twice as powerful as abrin, but when applied to the eye their action is reversed. Moreover, it is possible by special treatment to render an animal immune against both. The practical inference to be drawn from the results obtained by Ehrlich is that by the use at first of dilute solutions of either abrin and ricin, and then carefully and slowly increasing the strength, all danger to the eye in using these solutions may be avoided, without at all diminishing their therapeutic effect.

STRONTIUM IN BRIGHT'S DISEASE.

C. Paul (*Sem. Méd.*, November 18th, 1891) has made a number of observations on the action of strontium salts both in man and in animals. He first employed the lactate (prepared by neutralizing a 10 per cent. lactic acid solution with strontium hydrate), but has latterly employed only the bromide and nitrate. As a test of their purity these salts should give no precipitate with chromate of potash. He corroborates Laborde as to the innocuity of these salts. Guinea-pigs will bear from 15 to 20 centigrammes given hypodermically, and much larger doses by the mouth. The salt can then be found in the liver, bones, urine, and fæces. From observation in a very large number of cases he concludes that strontium is indicated, and gives very good results, in certain varieties of nephritis—parenchymatous, rheumatic, strumous, and gouty; it is also useful in the nephritis of puerperal or pregnant women, etc. Up to the present it has appeared ineffective in interstitial nephritis and in the renal lesions of tuberculosis or syphilis. Lastly, when the renal affection has arrived at the period of insufficiency or uræmia strontium is utterly useless.—*Brit. Med. Jour.*

METHYL VIOLET IN AFFECTIONS OF THE AIR PASSAGES.

Lincoln (*N. Y. Med. Jour.*, October 31st, 1891) says that methyl violet is very efficacious in checking chronic suppuration due to diseased bone after removal of the latter, as well as in ulceration of mucous membrane, particularly aphthous affections of the mouth. In acute follicular inflammation it is also useful, and especially so in chronic follicular affections of the tonsils and soft palate associated with the growth of micro-organisms (leptothrix). He used it in two cases of diphtheria, which recovered without sequelæ. One of these was a severe case of nasal diphtheria, in which the membrane went on spreading in spite of the application of sprays of corrosive sublimate, iodine, and carbolic acid, but yielded to the remedy. He has also had very satisfactory results with it in ozæna, both syphilitic and non-syphilitic. The drug has a drawback of staining the skin.

BENZONAPHTHOL A NEW REMEDY IN URÆMIA.

In the *Répetoire de Pharmacie* MM. Yoon and Berlios give an account of this new naphthol compound hitherto mentioned by us. Benzonaphthol is a benzoate of beta-naphthol prepared by the interaction of beta-naphthol with benzoyl-chloride, the effect of which is that the benzoyl group (C_7H_5O) takes the place of a hydrogen atom in the beta-naphthol. Its constitution is therefore, $C_{10}H_7C_7H_5O.O$. The resulting product, purified by crystallization from alcohol, is obtained in white, microscopic crystals, but may also be got in prismatic needles, if desired. It is without color, and is practically insoluble in water, soluble in rectified spirit to the extent of 2 or 3 grains in an ounce, and soluble 1 in 3 of chloroform. Benzo-naphthol is proposed as an intestinal antiseptic, preferable to beta-naphthol. In the system benzo-naphthol is split up into beta-naphthol and benzoic acid, the latter being eliminated by the urine as benzoic and hippuric acid. The therapeutic trials made with it show that it is as efficacious as betol and beta-naphthol, diminishing the toxicity of the urine considerably. It may be given to the extent of 5 gm. per day to adults, each dose of 50 cg. being enclosed in a cachet or suspended in a suitable mixture.

ACUTE AND CHRONIC DYSENTERY.

Dr. P. B. Green, of Wytheville, thinks that for the most part dysentery should be treated as a septic disease by antiseptics, such as iodoform, salicylic acid, creasote, naphthalin, etc. Sodium salicylate was perhaps the one to be generally preferred. Another good formula was—

℞ Carbon bisulphide.....ʒ vj.
Water.....ʒ xvj.
Spirit of peppermint.....gtt. xxx.
M. Shake well and let settle. Sig. Eight to ten drops in milk or water several times a day.

If no improvement in a week, then he used an injection, such as—

℞ Laudanum.....ʒ iij to iv.;
Oil of turpentine.....ʒ iijss.;
Powder gum arabic..... } āā ʒ ss.;
White sugar..... }
Camphor water.....ʒ iij.
M. Sig. Teaspoonful every four or six hours.

If hæmorrhage took place, he used ergotol hypodermically. Treatment by rectal injections of antiseptics had invariably proved successful in adults, and in most cases in children except infants. He preferred warm solutions of mercuric bichloride (from 1 to 10,000 to 1 to 3,000) every six to twelve hours. Listerine, salol, fluid extract of hydrastis, and the salicylates were other good antiseptics.

Dr. Bedford Brown, of Alexandria, suggests the following: Begin treatment with calomel as a cathartic, and follow this by a cleansing dose of Epsom salts. Then begin with antiseptic injections—about two drachms of carbolic acid to two or more pints of water. By the mouth, give a tablespoonful every three hours of—

℞ Aromatic sulphuric acid.....ʒ ij.;
Sulphate of magnesium.....ʒ ss.;
Deodorized tincture of opium.....ʒ ij.;
Syrup of orange-peel.....ʒ j.;
Peppermint water.....ʒ iij.;
Water.....ʒ ij.
M.

Occasionally full doses of Epsom salts were often needed to relieve congestions, correct secretions, etc. In severer cases, use more decided antiseptics, such as naphthalin, salol, and phenacetin, five grains of each every three hours, and irrigate the bowels twice daily with creolin. If adynamia occurred, marked by intensely fœtid discharges of blood mixed with mucus, pus, sloughs, etc., use injections of an ounce or two of hydrogen peroxide in a pint of water. Ichthyol dissolved in mucilage was also good. In threatened collapse, besides caffeine hypodermically, give one-hundredth grain each of atropine, strychnine, and nitroglycerine. In malignant hæmorrhagic forms, give half an ounce of turpentine in a pint of emulsion, and repeat the following every two or three hours:

℞ Opium.....gr. ss.;
Tannin.....gr. ii.;
Strychnine sulphate.....gr. $\frac{1}{50}$
Iodoform.....gr. j.;
Creasote.....gtt. j.
M.

In chronic dysentery, the septic fæcal matter, by constantly passing over the raw or wounded surfaces, kept up the septic condition. Tepid-water irrigations, followed by half-gallon injections twice a day of solutions of hydrogen peroxide, creolin, or ichthyol, would do good. It was best to administer these irrigations through a soft-rubber tube, about fifteen inches long, passed well up into the colon.

SALICYLATE OF SODA IN PLEURISY WITH EFFUSION.

Having used salicylate of soda in many cases of pleurisy with effusion with success, S. Déri (*Pest. Med.-Chir. Pr.*, No. 26, 1891) formulates his conclusions as follows:—

1. The salicylate-of-soda treatment will absorb pleuritic effusions even after being present for a long time.

2. In addition to its well-known diapho-

retic action, salicylate of soda appears to exert a specific action upon pleuritic effusions (as it does in polyarticular rheumatism.)

3, Inasmuch as cases treated by the salicylate of soda do not suffer relapse, the author believes that surgical intervention in pleurisy with serious effusion is seldom necessary, and may be considered even of secondary importance.—*Zeitschrift für Therapie*, No. 15, 1891, p. 117.

INCESSANT HICCOUGH RELIEVED BY LAVAGE OF THE STOMACH.

Dr. Everett J. Brown, writes in the *Medical Record* as follows:—

Reading in the daily press lately several accounts of a most persistent case of hiccough which had lasted many days and which was baffling the skill of the local medical fraternity, recalls to my mind a case of the same trouble which came under my care while a resident physician in Cook County Hospital, Chicago, of which case I find I have complete notes:

S. S——, a Russian peddler, aged twenty-seven, admitted to hospital April 30, 1888. Had always been in good health; on admission complained only of a persistent and incessant hiccough, which continued night and day; it had already lasted one week; he was thoroughly exhausted from loss of sleep and the pain and soreness produced by the constant contractions of the diaphragm; the usual remedies for these cases, such as morphine, bromide and chloral, ether, cannabis indica, bismuth, soda, and atropine, were each tried, but with little or no effect; morphine in large doses would relieve for one or two hours and allow the patient some sleep; electricity applied to the epigastrium and to the phrenic nerve was of no avail.

On examination over the region of the stomach that organ was found to be considerably dilated and to contain a large quantity of fluid; there were no external signs of a tumor or other pyloric obstruction; thinking that the dilatation of the stomach and the retention of fermenting food might be a cause of the hiccough I introduced a siphon-tube into the stomach and thoroughly washed out that organ; at least two quarts more of fluid were removed than had been introduced through the tube, and that which was removed was in a high state of fermentation. After this operation the hiccough entirely ceased and the patient had his first good night's sleep in sixteen days. He was discharged two days later with no return of the trouble.

THE LACTIC ACID TREATMENT OF DIARRHŒA.

In a number of cases of diarrhœa due to various causes, including phthisis, typhoid fever, erysipelas, and intestinal catarrh, which Dr. Shchegoleff, according to a paper he has published in the *Meditsinskoe Obozrênie*, treated by means of lactic acid, a successful result was obtained in two days in fifteen, in three days in five, and in four days in three. In twelve cases of exanthematous typhus the treatment failed to have effect, but in thirteen others it was successful. The preparation used was an aqueous solution sweetened with syrup. In this form the drug was well tolerated, and no unpleasant symptoms were produced.

The quantity of lactic acid given per diem averaged about 115 grains, or little more than half that given by M. Hayem, who first recommended this treatment, and this may perhaps account for some of the failures of the Russian practitioner. Acting on the advice of the latter, Dr. Chernisheff, who has also published an account of his cases, prescribed lactic acid in three cases of acute intestinal catarrh, in six of chronic gastro-intestinal catarrh, also in eight of diarrhœa due to phthisis, and in three of diarrhœa complicating Bright's disease. In all these cases good, sometimes striking, results were obtained. Thus several cases of simple catarrhal diarrhœa were relieved in from two to five days. In six cases of non-specific diarrhœa in phthisical persons the diarrhœa ceased the day after the commencement of the treatment. In one case of chronic gastro-intestinal catarrh the diarrhœa ceased on the third day from the commencement of the lactic acid treatment, but reappeared when it was stopped. Two days more of the treatment served to effect a more permanent cure. Notwithstanding the observations of MM. Hayem and Lesage on the value of lactic acid in the diarrhœa with green stools of young children (see THE LANCET, vol. i. 1887, p. 1149, and vol. ii. 1887, p. 1020), according to whom lactic acid destroys the bacillus on which the condition depends, this medicament is rarely used, and indeed, is not generally known to have any effect on infantile or other diarrhœa.—*Lancet.*

A charming bit of natural history, by Ernest Ingersoll, describing the habits and characteristics of "Our Gray Squirrels," with illustrations by J. Carter Beard, was one of the attractive features of *Harper's Magazine* for March.

MEDICINE.

RETURN OF SENSIBILITY AFTER FOURTEEN YEARS' LOSS.

Dr. Walton relates an interesting case in the autumn number of the *Journal of Nervous and Mental Diseases.* The patient was a man of twenty-nine, who had had anæsthesia of the left hand, more especially in the index finger, where it had persisted for fourteen years as the result of an injury to the finger. The scar of the old injury to this finger was a linear one extending diagonally across the palmar side of the index finger, and it was very sensitive to deep, and less so to superficial, pressure. The patient was neurotic, run down with hard and incessant work, and had formerly suffered from extensive anæsthesia of the left arm, and from patches of anæsthesia in other parts. He was first treated with galvanism and ordinary tonic remedies, but as there was no improvement, after a few weeks an operation was resolved upon. An incision an inch in length was made over the digital branch to the left index finger, and on this nerve a small neuroma was found and, together with half an inch of the nerve, removed. The improvement in the case was slow at first, but more rapid afterwards, and a year after the operation recovery was complete, the sensibility being restored where it had been lost, and the once painful part now quite painless. The patient's general condition had also improved, and from being thin and neurasthenic he had come to look stout and well. The restoration of the function of a sensory nerve which had been in abeyance for fourteen years is very interesting, and should be encouraging with regard to the operative treatment of peripheral nerves, even in cases apparently hopeless.

LEUKÆMIA ACUTISSIMA.

Guttmann (*Berlin. klin. Woch.*, November 9th, 1891) relates a case of severe leukæmia, which proved fatal four days and a half after the onset of the first symptoms. The patient, a spare boy, aged 10, after complaining for some time of debility, was suddenly seized with hæmaturia, numerous ecchymoses appearing in different regions of the body; the next day some bleeding also took place from the nose and mouth. Two days later complete unconciousness set in, together with paralysis of the right side, some twitching of the muscles, and priapism. Microscopical examination of the blood showed that the proportion of white to red corpuscles had enormously increased, being as 1 to 1.4. These symptoms continued for two days, when death took place, four days and a half after seizure. *Post mortem* numerous ecchymoses were found on the skin and on the surface of the heart. The thymus was greatly enlarged, measuring nearly as much as the heart. The spleen amounted to three times its usual size; the pelvis of the right kidney contained blood. The left lateral ventricle of the brain was occupied by a large blood clot, which had destroyed a considerable portion of the corpus striatum, optic thalamus, and neighboring brain tissue. A small clot was also found in the right parietal lobe. No marked enlargement of the lymphatic glands was present. This case, says Guttmann, exhibits an unusually rapid development of acute leukæmia, death being caused by the cerebral hæmorrhage. The other unusual symptoms were the swelling of the thymus and the priapism, the latter being possibly due to hæmorrhage into the corpora cavernosa. No cause for the illness could be discovered. Bacteriological examination of the blood gave a negative result.—*Brit. Med. Jour.*

PODOPHYLLOTOXINE.

Dr. Kürsten, in investigation the rhizome of podophyllin, taking up the study where Podwyssotski left off, has found that the substance called podophyllotoxine by the latter author is in reality a most complex material. Precipitating a chloroform solution of it by means of the addition of petroleum ether, Kürsten obtained a crystalline body of exceeding activity. This body he subsequently obtained directly from the root by exhausting the latter in chloroform, and subsequent precipitation of the chloroform solution with petroleum benzine. It exists in the root in the quantity of 2 parts to 1,000. The formula, established by Kürsten, is $C_{23}H_{24}O_9$, with 2 molecules of water of crystallization. Kürsten proposes the name podophyllotoxine for this definite product.

THE ORIGIN OF CITRIC ACID IN MILK.

With ordinary fodder citric acid occurs in goat's milk, as in cow's milk, to the extent of 1 to 1.5 gm. per litre; but the amount is liable to considerable fluctuations, being sometimes twice as great as at others (calculating it upon the total solids). It does not appear to be derived from the citric acid present ready formed in the fodder, as it also occurs, though in smaller quantity, in human milk. Moreover, citric acid added to the fodder does not increase the amount found in the milk, and feeding exclusively upon materials free

from citric acid has no effect upon the quantity excreted. Milk secreted in a state of hunger contains the normal amount of citric acid. Citric acid in milk is apparently not derived from the cellulose undergoing digestion in the intestines of herbivora, as excretion goes on when food is withheld or meal substituted for ordinary fodder; this is consistent with the fact that in the human subject (where no digestion of cellulose takes place) 0.54 to 0.57 gm. of citric acid per litre of milk is formed.

GASTRIC HEADACHE.

Dr. Westphalen has found that toxic substances in the stomach under certain conditions are capable of producing, through absorption, disturbances of circulation in the central nervous system and its associated parts which result in headache. A complete absence of hydrochloric acid in the stomach contents was found, and when this acid was prescribed complete recovery followed. The theory advanced for the beneficial action of this drug is that ptomaïnes or toxines of micro-organisms exert an injurious influence only when there is a deficiency in the quantity of free mineral acid in the stomach. Headache may also be prevented in such cases by administering the acid directly after the patient has eaten articles which have previously always been followed by headache. The nature of the noxious substance is at times obscure, as in instances where indigestion, headache, and urticaria follow the use of chocolate or strawberries, but in such cases also hydrochloric acid acts well.—*Berliner Klinische Wochenschrift,* No. 37, 1891.

A GASTROLITH IN MAN.

Dr. Kooyker has reported in the *Zeitschrift für Klinische Medicin* another case of gastric calculus—a condition which, though common enough in animals, is so rare in man that so far only seven cases have been reported. Dr. Kooyker's case was that of a man fifty-two years old, in whose lifetime it had been impossible to make a positive diagnosis, though some neoplasm of the stomach was suspected. The patient died from exhaustion. At the post-mortem examination a concretion was found in the stomach, almost entirely filling its cavity, which weighed 885 grammes, and was eighteen centimetres in length. The microscopic examination resulted in finding starch, vegetable cells, chlorophyll, and vascular tufts, while hair and other animal elements were entirely absent.—*Lancet.*

OBSERVATIONS ON THE SECRETION OF BILE IN A CASE OF BILIARY FISTULA.

In this paper, A. W. Mayo Robson (*Proceedings of the Royal Society,* vol. xlviii) gives an account of the observations made upon the biliary secretion in a patient with obstruction of the common bile duct, and in whom an artificial biliary fistula between the gall bladder and external surface had been produced, through which the whole of the bile was discharged for fifteen months. During this time the digestion was unimpaired, bowels regular, without the use of aperients, and the odor of the fæces did not differ from that of a healthy motion. Menstruation ceased while the fistula was patent, but became regular and normal as soon as the bile was again turned into the intestine by operative interference.

The following are the principal conclusions which Mr. Mayo Robson draws from his observations:

1. The bile is probably chiefly excrementitious, and, like the urine, is constantly being formed and cast out.

2. Though the bile probably assists in the absorption of fat, its presence in the intestine is not necessary for the digestion of such an amount of fat as is capable of supporting life and keeping up nutrition. Much fatty matter in the patient's food did, however, produce a marked effect—a sickly feeling, loss of appetite, and more fat than normal in the fæces.

3. Increase in body weight and good health are quite compatible with the entire absence of bile from the intestines.

4. The antiseptic properties of bile are unimportant; this was tested only by the character of the fæces, which neither by odor nor aspect indicated any irregular fermentative process for the fifteen months during which no bile passed into the intestine.

5. Whatever little antiseptic quality bile may have is probably derived from its admixture with the gall bladder fluid.

6. The supposed stimulating effect of the bile on the intestinal walls is not necessary for a regular action of the bowels.

7. The quantity of bile excreted in the twenty-four hours during health in a person of average weight may vary between 39 oz. 4 dr. and 25 oz. 6 dr., with an average of 30 oz; 2½ ox. of this is due to the fluid secreted by the gall bladder, as determined in a case of the author's, in which an operation for the relief of a gall bladder distended by gall stones, with stricture and occlusion of the cystic duct, was followed by a fistula of the gall bladder, from which a clear and somewhat viscid fluid issued, containing no bile

constituents. This was held to be the normal secretion of the gall bladder.

8. More bile is excreted during the day than at night, the excess varying between 5 oz. and 3 dr.

9. The excretion of bile seems to go on constantly and with great regularity.

10. The excretion is apparently not materially influenced by diet.

11. The pigment of fresh human bile is biliverdin, the color of the fresh bile was always green.

12. The supposed cholagogues investigated seem to rather diminish than increase the amount of bile excreted. These drugs were—

(*a.*) *Calomel*, 5 grs. at 7 P. M. caused a slight aperient effect the next morning, but the amount of bile excreted within ten hours after the administration was less than the amount for the ten hours before the drug was given, by over 2 ounces.

(*b.*) *Euonymin*, 4 gr., less bile was excreted in the ensuing four hours than in the four hours before administration.

(*c.*) *Rhubarb*, ½ oz. and 1 oz. of the tincture could not be said to cause any increased flow.

(*d.*) *Podophyllum* was given on one occasion, and no cholagogue effect was noticed.

(*e.*) *Carbonate of soda*, in the form of aërated soda water, was given, and produced in two hours a maintained increased flow, not succeeded by a marked diminution.

(*f.*) *Iridin*, 4 gr. apparently increased the flow temporarily (though a greater flow was observed at the same time of the day on other occasions when no drug had been given), but without augmenting the total quantity in twenty-four hours.

(*g.*) *Turpentine*, 15 min. given in capsules every four hours. Although an increase was apparent on the second day, yet the daily amount of bile discharged in the twenty-four hours was not so much as on many days when no turpentine was being given. The odor of turpentine was perceived in the bile soon after its administration.

(*h.*) *Benzoate of soda* caused no positive increase in the flow of bile, contrary to the results obtained on dogs by MM. Prévost and Binet.—*Medical Chronicle.*

SPASMS OF THE GLOTTIS.

The following formula (*Lo Sperimentale*, No. 21, 1891) is praised:

℞

Chloroform	gtts. 5–10.
Aq. destillat.	gms. 25.
Glycerine	gms. 5.

A teaspoonful every half hour.

SURGERY.

THE RADICAL CURE OF HYDROCELE BY EXCISION OF THE SAC.

In the *Lancet* of Sept. 10, 1887, and Oct. 26th, 1889, Dr. Southam recorded seven cases of hydrocele treated by excision of the sac, and also directed attention to the favorable results which follow this method of radical cure. The three cases mentioned below (*Lancet*, July 25, 1891), which have recently been under his care, are good illustrations of some of the conditions in which this treatment is especially valuable. In Case 1 the hydrocele was of the variety known as "multilocular," being composed of a number of separate cysts, and therefore not likely to have been cured by injection. Cases 2 and 3 would also have been unsuitable for treatment by injection, for in each the sac-wall was so thick and rigid that it was incapable of collapsing after the evacuation of its contents by tapping, consequently a large thick-walled sac remained, which was best excised, for if treated by the alternative method of radical cure—viz, by "incision"—its obliteration by a process of granulation would have been a tedious and uncertain mode of healing. In all three cases excision of the sac, which for reasons given in the papers above referred to, he believed to be far preferable to "incision," was followed by the most satisfactory results.

Case 1. *Multilocular hydrocele; excision of sac; recovery.*—F. E——, aged forty-three, sent by Dr. Blayney of Middleton, was admitted on Feb. 18, 1891, suffering from a hydrocele of the tunica vaginalis, which had been present for several years, and had been tapped twice; on the first occasion about eight ounces of clear fluid had been evacuated, but on the second only a few drops came away, and there was no diminution in the size of the swelling. As he was anxious to have a radical cure performed, and did not wish to run the risk of an unsuccessful injection, it was resolved to excise the sac. The operation was performed on Feb. 20th. On laying open the sac of the hydrocele the cavity of the tunica vaginalis was found to be divided by delicate septa into a number of compartments, some quite distinct, others communicating with one another. The tunica vaginalis having been separated from its connections with the scrotal tissues, the whole of the parietal layer was removed by dividing it close to its reflection on the testicle and cord. All bleeding having been carefully arrested, the wound was closed, no drainage being employed. Repair took place without any sup-

puration; the patient was up on the twelfth, and left the hospital on the nineteenth day after the operation, the wound being firmly healed.

Case 2. *Hæmatocele after tapping a hydrocele; previous unsuccessful injection with iodine; excision of sac; recovery.*—W. R——, aged twenty-three was admitted on April 27th, 1891, with a history of a hydrocele of the tunica vaginalis, which had been present for about ten years. It had been previously tapped twice, and once injected with iodine, The last tapping had been performed three days previously to admission, when six ounces of clear straw-colored fluid were drawn off; in the course of twenty-four hours the swelling reappeared, and the integuments covering it became dark and discolored. As it was evident that the case was one of hæmatocele, following the operation of tapping a hydrocele, it was resolved to lay open the sac, evacuate the blood, and at the same time perform a radical cure by excising the tunica vaginalis. The operation was performed on May 2d. A free incision was made into the cavity of the tunica vaginalis, which was found full of sanious fluid and portions of blood-clot, and the sac-wall, which was extremely thick and of dense fibrous consistence, was dissected out and removed up to its reflection on the testicle. The wound was then closed, a drainage-tube being brought out at its upper and lower margins. Healing quickly took place, and the patient left the hospital on the twenty-first day after the operation.

Case 3. *Suppuration in tunica vaginalis after tapping a hydrocele; excision of sac; recovery.*—E. S——, aged sixty-two years, was sent on Feb. 16th, 1891, by Dr. Fletcher of Bury, suffering from a large hydrocele of twenty years' duration, for which no treatment had previously been adopted. On tapping the tumor, which was quite opaque, about a pint of thick brownish fluid was drawn off. After the evacuation of the fluid the sac-wall could be felt through the scrotal tissues to be extremely thick and of such rigid consistence that it was incapable of collapsing. On March 27th the hydrocele was tapped again, about the same quantity of fluid of a similar nature being removed. It gradually refilled and subsequently became extremely painful and tender. On April 25th he was admitted into the infirmary. The integuments of the front of the scrotum were in a gangrenous condition, and the adjacent parts were much inflamed. The same day a free incision was made into the cavity of the tunica vaginalis, which was full of pus; the tunica itself which was thickened and calcified, was dissected out, and as the testis, though healthy, was greatly atrophied, it was also removed; a considerable portion of the gangrenous scrotal integument was also taken away. (The patient was the subject of an irreducible inguinal omental hernia on the same side. As the sac of the hernia was intimately adherent to that of the hydrocele, a radical cure was also performed on the hernia at the same time. A ligature was placed round the neck of the hernial sac as high up as possible, and the sac and omentum were then removed on the distal side of the ligature.) The margins of the upper part of the wound were then brought together by a few sutures, the lower part being left open on account of the inflamed condition of the scrotal tissues. Healing was somewhat slow, as there was some sloughing of the margins of the lower portion of the wound; it was, however, sufficiently advanced to allow the patient to leave the hospital exactly a month after the operation, a small granulating surface still being present.

TREATMENT OF CAUSES OF LIMPING.

Simon states (*Arch. f. Kimlich.*, xii., 5 and 6) that one of the commonest and most important causes of lameness in children is coxitis. It calls for attention at the beginning, while it is still an arthritis and before there is tumor albus, abscess, or luxation of the head of the femur. Treatment should be general and local, the former having special reference to general disease like scrofula, and consisting in the use of tonics and stimulants, cod-liver oil during the winter, and phosphate of lime. The local treatment consists primarily in immobilization, and whatever form of apparatus is used this must be a primary consideration. The author approves of the extension apparatus of Guersant, which is provided with weights for overcoming muscular contraction. It is sometimes necessary to use chloroform anæsthesia as an assistant to the apparatus in overcoming this contraction. The Guersant apparatus allows one to make the necessary inspection of the diseased joint and to use the necessary local means. If the leg has no defective position it is well to use that form of the Guersant apparatus which fixes the pelvis and trochanter completely. Verneuil's and Bonnet's apparatuses are also recommended, though the expense of the latter may be considered an objection to it. If the disease has lasted a long time, and the leg is in a vicious position, with or without ankylosis, re-dressment under chloroform

anæsthesia is indicated, and then immobilization if inflammatory conditions have disappeared. Abscesses should be opened and treated with iodoform-ether. If healing has advanced so far that a relapse into a bad position is not to be feared, the immovable apparatus may be replaced by a movable one. After one to three years, healing will usually be so far advanced that the patient can go about on crutches. Since relapses are to be feared, one must not begin to lay aside supporting apparatus until ankylosis of the joint in a good position has occurred. Coxitis is one of the most deceptive of diseases, and almost always ends with shortening of the leg to a greater or less extent. Another cause of lameness consists in congenital luxation of the hip-joint. This is usually incomplete and increases by degrees. By using suitable apparatus the destructive process in the head of the femur may be retarded. Arthritis of the knee- and ankle-joints may be treated at first with revulsives, vesicants, and immobilization. Internally one may give salicylate of soda in the acute stage, and in chronic cases tincture of colchicum in five- to ten-drop doses, suspending its use for a time after eight or ten days. Tonics must also be employed, also massage and weak currents of electricity. Passive movements of the joint should also be practised to prevent stiffness. If there is periostitis or a small abscess, one may inject iodoform-ether; if there are large abscesses, curetting under the most careful antisepsis is advisable. If there is inflammation of the trochanter, immobilization is of first importance, and then one may use revulsives or actual cautery, burning even to the bone. To relieve the pain one may give belladonna and hyoscyamus, the limb being enveloped in cotton.

Another cause of lameness is infantile paralysis. Should it begin with fever, the treatment should first consist in derivatives, such as flying blisters and the actual cautery, then hot-air baths to cause profuse sweating. At night one may give chloral, and during the day aconite and nux vomica in doses of ten drops or less. When the febrile period is over the galvanic current may be used every three days for ten minutes at a time. Carefully regulated gymnastic exercises will also be of service, also sulphur-baths, salt-baths, and tonics—especially nux vomica.

In paralysis from brain lesion electricity is not indicated. One must lessen rather than increase the excitement of the nervous system. If the brain lesion is of syphilitic origin, iodide of potash should be used. If there is sclerosis of the brain, bromide of potash and iodine may be given in combination. All excitement must be avoided, and the treatment be directed to that lesion which is the fundamental cause of the lameness.—*Amer. Jour. Med. Sci.*

VARICOSE ULCERS OF THE LEGS.

Dr. David Fejér publishes in the *Orvosi Hetilap* an account of his treatment of ulcerated varicose legs, which has the advantage of not requiring any long confinement of the patient in the recumbent posture. He first cauterizes dirty-looking ulcers, if they are covered merely by a thin layer of pus, with nitrate of silver, those which are covered by a thick diphtheritic layer being treated with chloride of zinc, while fetid and gangrenous ulcers are destroyed by the actual cautery. According to the applications, the dressing is changed in three, five, or ten days, during which time the patient has his legs elevated. Before the dressing is applied the ulcers and the surrounding skin are washed with water or a sublimate solution of the strength of 1 to 2000. A thin layer of iodoform is then dusted over the ulcers, which are ultimately covered with a mercurial plaster spread, after softening to the thickness of two millimetres on thin calico cut somewhat larger than the circumference of the ulcers. This is followed by a cotton-wool tampon. The leg is then covered with a thin layer of Brun's cotton-wool, after the skin has been dusted with some innocuous powder. It is convenient to steady the dressing with a gauze bandage, so that the fine flannel bandage which completes the dressing may be easier of application. In some cases the plaster may be followed by an elastic bandage, which is especially appropriate in elephantiasis of the foot and in indurated ulcers, and may be combined with massage of the leg. The best powder for dusting the skin as a prophylactic against eczema is oxide of zinc or bismuth. Massage may even be practised on the bandaged leg, provided the ulcers have assumed a clean appearance. Under this treatment the patient may walk about in from four to ten days, and may after a few days more attend to his business. He must, however, when resting, always lie down, and even when he is sitting his legs must be in a horizontal position. Another advantage accruing from this treatment is that the dressing does not require changing until after three or four, and later on only at intervals of eight or ten, days; and that indurated ulcers of long standing are made to heal by this process, provided no destruction of tissue has taken place which cannot anatomically be

replaced, and provided also that the patient does not suffer from any serious constitutional affection. Dr. Fejér does not recommend skin-grafting, but prefers to loosen the skin surrounding the ulcer with the knife for a distance of ten centimetres or more, and then to approximate the loosened portions. This must, of course, only be done after the ulcer has been cleansed, and after the skin and the connective tissue underneath have become soft, as gangrene would otherwise occur. Some treatment should be continued after the varicose ulcers have healed. Dr. Fejér thinks it sufficient in slight cases for the patient to assume the recumbent posture twice or three times a day for five or ten minutes each time, and to move the leg about while elevated. Persons who cannot spare the time for the above dressing may substitute an elastic stocking, which, however, must be examined every morning *in situ*, and altered to the decreased size of the leg, as the latter frequently swells during the day while the patient is walking about.—*Lancet.*

LIGATION OF ARTERIES.

In an excellent lecture by Prof. Ashhurst, reported in *Gaillard's Medical Journal*, the following practical conclusions are formulated:

1. The best material for ligatures, as far as my experience enables me to judge, is catgut, prepared with alcohol and oil of juniper for ordinary operations, but with chromic acid for ligations of vessels in their continuity. For the lateral closure of veins I am disposed to recommend fine carbolized silk.

2. In dealing with arteries, the ligature should be tightly tied so as to divide the inner and middle coats of the vessel. In cases of hæmorrhage in continuity, double ligatures should be used, and the artery may properly be divided between them. In cases of aneurism, a single ligature applied through a very small opening in the sheath is safer. In dealing with the trunk veins of the extremities, the dangers attending complete occlusion are so grave that it is worthy of consideration whether, in cases of punctured or longitudinal wound, lateral closure in some form might not be advantageously substituted for the ordinary double ligature.

3. In the treatment of hæmorrhage in the continuity of an artery, the vessel should be tied where it bleeds, and on both sides of the bleeding orifice. In the treatment of aneurism, on the other hand, the ligature is best applied at a distance, as in the Hunterian method.

4. In cases in which the great veins are wounded, the vein only should be tied. Simultaneous ligation of the artery increases the risk of gangrene by cutting off the *vis a tergo*, which is needed to maintain the circulation.

5. In the surgical treatment of aneurism, digital compression on the cardiac side of the tumor may be considered the "ideal" method. When it it not applicable, or if it has failed, the Hunterian mode of ligation is the best substitute, and Anel's method, the "old operation," and the various plans of distal ligature, should be reserved for cases to which Hunter's method is not applicable. For aneurisms of the innominate or thoracic aorta, simultaneous ligation of the carotid and subclavian of the affected side is preferable to the ligation of either artery separately. For subclavian aneurism, shoulder-joint amputation is to be recommended as a modified distal operation.

OBSTETRICS.

ONE BREAST OR TWO.

In a recent number of the *Lyon Medical*, Sabaite referred to some observations he had made upon the mortality of infants nursed by women who for some reason used only one breast. He found that the death-rate is much higher in these cases than in those where both breasts were employed. In thirty-two of the former, among hospital patients, the infantile mortality was forty-eight per cent.; in the same number of the latter, under similar circumstances, the mortality was but twenty-eight per cent.—*Medical Press.*

TEMPORARY BLINDNESS DURING LACTATION.

Nettleship (*Ophth. Hosp. Rep.* xiii, 2. December 1891), reports several cases of temporary failure of sight in women during lactation. These cases are distinguished from those of retinal disease due to the albuminuria of pregnancy, and also from those in which blindness results from severe *post-partum* hæmorrhage. He has not seen any of the cases he describes during the time of blindness, but the ophthalmoscopic appearances present at various periods after the attack, point with more or less certainty to a previous optic neuritis. He believes that these cases will probably be found to belong to the same group as the optic neuritis now and then met with in chronic anæmia.—*Brit. Med. Jour.*

EARLY DETECTION OF PREGNANCY.

Dr. R. L. Dickinson claims (*Brooklyn Med. Jour.*) that he can determine pregnancy at a very early period. According to him the most distinctive changes in early pregnancy are bulging and elasticity of the upper part of the uterus. When the bulging is posterior, it is usually very distinct, resembling a ledge. Of his cases, the changes were demonstrated, and the cases diagnosed as pregnancies, one on the sixteenth day after a single coitus, one case on the nineteenth day, one on the twenty-first day, several between the twenty-second and twenty-fifth. He knows perfectly well that the spermatozoa may lie some days waiting for the ovum, and that the ovum may remain some days before it may meet with the spermatozoa, also that impregnation usually occurs in the tube, and then that the ovum must slowly travel into the uterus and find lodging, and therefore we would have to subtract ordinarily some days from his statement. For instance, a case of pregnancy nineteen days after coitus we might have to report as only twelve days pregnant, but he takes it in such a case, where the uterus distinctly enlarges as early as the nineteenth day after a single coitus, that impregnation of the ovum must have occurred in the uterus, in order to permit the enlargement to have occurred so rapidly.

The main point which he wishes to emphasize is, that the elasticity, resiliency and bulging of the body of the uterus are far more valuable as signs of pregnancy than the compressibility at the junction of the body and cervix (Hegar's).

MISAPPLICATION OF THE OBSTETRIC FORCEPS.

M. McLean (*N. Y. Jour. of Gyn. and Obstet.*, November 1891) says that in every case requiring forceps there is a proper time for operation. Every minute's delay after that time may be harmful. Too early application is yet more serious. The fretfulness of the patient in the first stage is not necessarily a warrant to interfere. The moulding of the head, the softening and dilating of soft parts of the parturient canal, the proper adaptation of the head to the canal, should be remembered as essentials in a normal case. The hand should always be used to determine the precise position of the head before introducing the blades. The head should be grasped so as to ensure the proper diameters opposed to the walls of the canal. In making traction, not only should the pelvic curve be respected, but the spiral action of the head should be encouraged by allowing the forceps handles to turn in the direction indicated by the non-resisting forces. The blades should be removed as soon as the face of the child can be manipulated through the recto-coccygeal tissues and the rest of the delivery completed by the hand. The forceps are too often applied in cases where the position of the child, the disproportion between the head and the obstetric canal, and other circumstances make it advantageous to select version instead of the instrumental operation. To apply the forceps in these cases indiscriminately and as a matter of routine, and then, after failing, to resort to version, is an almost reckless disregard of cardinal rules of obstetrics. Too many operators look upon version as the more serious operation, because in nine-tenths of the cases where version has been attempted it has, unfortunately, been undertaken in a case already damaged by misapplied forceps.—*Brit. Med. Jour.*

GYNÆCOLOGY.

LIPOMA OF THE TUBE.

Parona (*Annal. di Ostet e Gin.*, 1891, No. 2) relates a case of removal of the appendages for myoma. On the right side a fatty tumor was discovered. It occupied half the broad ligament, and the ovary, quite healthy, hung from it. The tube was embedded in the tumor, and only the fimbriated extremity was visible. The origin of the tumor was ascribed to a tubal fimbria.

THE TREATMENT OF ENDOMETRITIS.

Kaltenbach (*Centralblatt für Gynäkologie*, 1891, No. 44) disapproves of the application of caustics, which may cause atresia of the cervical canal. Forcible dilatation often repeated is also reprehensible, since lesions of the mucosa are thus produced, infection of which may readily give rise to parametritis through the medium of the lymphatics. Even if infection is avoided, repeated dilatation, irrigation, or applications to the interior of the uterus keep the patient in a constant state of nervous irritability, detrimental to her health, aside from the danger of causing toxic symptoms. Many cases of catarrh fail to improve because proper precautions are not taken to avoid fresh infection. The vulva and vagina should be thoroughly disinfected before any application is made to the endometrium. After this has been done, the uterine cavity should first be cleansed with sterilized gauze, followed by an application of strong tincture of iodine. In cases of long

standing the thorough use of the curette should precede these applications, this treatment to be repeated only at long intervals.

Mackenrodt (*Ibid.*) does not hesitate to adopt the same treatment (injection of tincture of iodine after curetting), even when the adnexa are secondarily affected, provided that the presence of suppuration is positively excluded. It is, of course, not begun until the acute stage has passed. Forty-five cases are reported, in none of which were any bad symptoms noted. Seventeen patients were cured and twenty-two were improved.

DISINFECTION OF THE HANDS.

Dr. H. A. Kelly, (*American Journal of Obstetrics*, December, 1891), after giving the details of a large number of experiments made by himself and his associates, gives the following conclusions as to the best method of disinfecting the hands:

Scrubbing the hands with especial attention to the nails,—not more than one millimetre in length,—for ten minutes in water, frequently changed, at about 104° F. Immersion of the hands in a solution of permanganate of potassium, made by adding an excess of the salt to boiling distilled water, until every part of the hands and lower forearms is stained a deep mahogany red or almost black color. They are then transferred at once to a saturated solution of oxalic acid until completely decolorized and of a healthy pink color. Washing off the oxalic acid in warm sterilized water.

By this simple process the hands are rendered more nearly absolutely aseptic than by any other known means.

The author has found that it is impossible to get rid of staphylococci by scrubbing the hands and nails from ten to twenty-five minutes with a sterilized brush, soap and water, temperature 104° F. The bichloride of mercury solutions as used, up to 1: 500, are not germicidal, as supposed. Previous erroneous conclusions as to the efficiency of the bichloride are shown to be due to an inhibiting action which may persist at least twenty-four hours after the last use of the drug. Hydrogen peroxide and lysol (four per cent.) were tested and found wanting.

In the present state of our bacteriological knowledge as to the causes of inflammation and suppuration, we are bound to use every means in our power to avoid sowing any unnecessary germs in our wounds. Soap and water are, Dr. Kelly believes, the best disinfectants, if we use but one, for they remove all germs which will come away easily. The bichloride of mercury, although dangerous on wounds on accounte of its property of coagulating and causing necrosis of albuminous tissues, has the valuable property of inhibiting those germs with which it comes into contact. Permaganate of potassium and oxalic acid are harmless to the hands and are germicidal. Soap and water plus the permaganate of potassium and oxalic acid are the only true germicides, and therefore the best disinfectants we possess to-day.

HELENIN IN THE TREATMENT OF LEUCORRHŒA.

In the *Archives de tocologie et de gynécologie* for December M. Hamonic relates his experience with helenin as a remedy. He has found it worse than useless in gonorrhœa, but capable of curing cervical leucorrhœa, even without topical treatment. He prescribes the following formula: Crude helenin, inulin, each, 15 grains; sugar of milk, q. s. Mix, divide into 100 pills. From two to four to be taken daily. The inulin is said to have no remedial power, and to be replaceable by powdered licorice or conserve of roses. Used as an injection, inulin simply irritates the vagina.

BENZO-NAPHTHOL.

A report of this new compound, by MM. Yvon and Berlioz, appears in the *Répertoire de Pharmacie*. It is a benzoate of beta-naphthol prepared by the interaction of beta-naphthol with benzoyl chloride, the effect of which is that the benzoyl group (C_7H_5O) takes the place of a hydrogen atom in the beta-naphthol. Its constitution is, therefore, $C_{10}H_7C_7H_5O.O$. The resulting product, purified by crystallization from alcohol, is obtained in white, microscopic crystals, but may also be got in prismatic needles if desired. It is without odor, and is practically insoluble in water, soluble in rectified spirit to the extent of 2 or 3 grains in an ounce, and soluble 1 in 3 of chloroform. Benzo-naphthol is proposed as an intestinal antiseptic preferable to beta-naphthol. In the system benzo-naphthol is split up into beta-naphthol and benzoic acid, the latter being eliminated by the urine as benzoic and hippuric acids. The therapeutic trials made with it show that it is as efficacious as betol and beta-naphthol, diminishing the toxicity of the urine considerably. It may be given to the extent of 5 gm. per day to adults, each dose of 50 cgm. being enclosed in a cachet or suspended in a suitable mixture.—*Chem. and Drug.*

PÆDIATRICS.

LOCAL TREATMENT OF THE THROAT IN DIPHTHERIA.

The cruel and useless practice of swabbing out the throat with caustic applications in diphtheria of the fauces has, I think, died out, but this method of applying astringents, such as perchloride of iron, or antiseptics and solvents, still survives. The diphtheria wards in the Hospital for Sick Children afford exceptional opportunities for observing the effects of various methods of local treatment; and, from long observation, I have no hesitation in condemning as injurious the system of brushing out. And this for several reasons. In the first place, on account of the distress it causes to the patient. In the case of a young child it involves a severe struggle; sometimes the help of two or three persons is required to overcome the fierce resistance, and to open the mouth and reach the fauces. It causes terror, excitement, heart strain and physical exhaustion—conditions most inimical in a disease tending to death by asthenia—and the distressing process has to be repeated frequently if it is to be effectual. Moreover, apart from this matter of the wear and tear involved, the rough treatment of the fauces probably does harm by causing abrasions of the surface, and thus favoring absorption of the local poison. We know how readily fresh raw surfaces of all kinds take up poisons which come in contact with them. Witness, for example, the communication of scarlet fever in surgical operations, the absorption of morphine from a blistered surface. If the diphtherial poison is rendered more available for circulation by the application of solvents, the infective absorption is liable to be still greater. The most rapidly fatal case of diphtheria from profound general systematic poisoning I ever have seen was one in which the throat was cleared of membrane by brushing out with papain.

I am sure that not only are the patients saved great distress, and doctors and nurses much trouble and anxiety, by the abandonment of the brushing-out process, but the results generally have been more satisfactory. Insufflation with iodoform or sulphur, or spraying with boric acid or corrosive sublimate solutions, are far more easy of application and more effectual in antiseptic action.

There are other errors in treatment of which I should like to say something, such as oppressive poulticing of the chest in pneumonia, obstructive to respiratory movement, and tending to increase the body heat; the administration of emetics in diphtheritic croup, which is utterly ineffectual except to depress and exhaust the patient; their frequent repetition in bronchitis and whooping cough when there is no extreme mucous obstruction of the air passage to justify it; the too free purging of rickety children suffering from laryngismus and convulsions under the belief that irritant matter in the alimentary canal is the sole cause of evil. But time forbids me to do more than allude to these things. I will merely add this word of advice. In treatment, consider as carefully what not to do as what to do. To avoid doing harm is as important as to effect positive good.—*Dr. W. B. Cheadle, in the Practitioner.*

SALICYLIC ACID FOR THE PREVENTION OF SCARLET FEVER.

Sticker reports the observations of G. De Rosa, who administered salicylic acid in doses of one to five grains, to sixty-six children exposed to infection during an epidemic of scarlet fever. Twenty-seven cases of the disease existed in the building when administration of the drug was commenced. Only three of sixty-six contracted the disease, the failure in these being ascribed to a longer exposure to infection.—*Centralblatt für klin. Med.*

INTUBATION OF THE LARYNX.

Ranke reported to the Congress at Halle (*Rev. des Mal. de l' Enf.*, December, 1891) the statistics of another year's experience of intubation of the larynx. These are more favorable than those of previous years collected last year; the improvement he attributes to (1) having a thead attached to the tube so that the nurse can withdraw it if necessary, (2) improved instruments, (3) greater skill and experience in the operators.

	First Series.		Second Series.	
	Cases.	Recoveries.	Cases.	Recoveries.
Intubation	413 ...	34 p. c.	348 ...	41 p. c.
Tracheotomy.....	866 ...	38 p. c.	237 ...	34 p. c.

Tracheotomy was subsequently performed 83 times in 348 cases intubated during the last year with six recoveries (7 per cent). The 348 cases were collected from the practice of various operators. Bokai, who had treated 109 cases by intubation, thought tracheotomy ought to be abandoned in hospitals. In his cases the tube had been retained for periods varying from 10 to 184 hours. The tubes were changed every two days.—*Brit. Med. Jour.*

HYGIENE.

EXPLANATION OF THE DANGER OF HIGH TEMPERATURES.

At the meeting of the French Association for the Advancement of Science, held at Marseilles, September 18, 1891, M. Maurel, of Toulouse, read a paper on the above subject. "We know," says M. Maurel, "in the first place, that an animal does not survive its leucocytes, and, again, that in man the axillary temperature is lower by 1° or 1½° C. (1.8° to 2.7° F.) than the temperature of the interior of the body. Now, it has been established, experimentally, that a temperature of 44° to 45° C. (111⅕° to 113° F.) kills our leucocytes in a few minutes; that in a temperature of 43° to 44° C. (109⅖° to 111⅕° F.) our leucocytes do not live an hour; finally, that in a temperature of 42° to 43° C. (107⅗° to 109⅖° F.) they may live for three hours, retaining all their activity, and that if this activity becomes lessened they may still, by lowering the temperature, be made to live for twelve hours. These experimental facts explain, to my mind, the danger of axillary temperatures above 41.5° C. (106.1° F.), since this temperature corresponds to 42.5° or 43.° C. (108½° to 109⅖° F.), which will kill our leucocytes, and consequently, also, the human body; it is for the reason that we never see a patient survive a temperature of 42° C. (107⅗° F.). It also explains the beneficial effect of lowering, by 1° or 2° C. (1⅘° or 3⅗° F.) a febrile temperature, since, instead of being in a temperature rapidly mortal, our leucocytes are exposed to a temperature in which they possess their maximum activity.—*La Semaine Médicale*, September 23, 1891, p. 385.

DISINFECTION OF ROOMS.

Dr. Vilandt (*Gazzetta degli Ospetali*, No. 82, 1891) disinfects rooms by means of a mixture of carbolic acid and ethereal essence of turpentine. One or two teaspoonfuls are poured into a tin dish full of hot water, which causes it to rapidly evaporate. This is kept in the patient's room during the whole time of the disease. (A Danish writer records a case of death where a similar evaporating apparatus, with a solution of carbolic acid, was kept boiling in an adult patient's room. The patient was suffering from diphtheria. He presented the symptoms of carbolic acid poisoning—carboluria, acute nephritis and uræmia.—Dr. H. B. Barfod, *Ugeskrift for Læger*, No. 24, 1891).

SYPHILITIC INFECTION THROUGH SHAVING.

In the *Berliner Dermatologischen Vereinigung*, Herr Oestreicher describes the case of a patient who contracted syphilis through a scratch he received in shaving. On the patient, a man about thirty years of age, a papulo-squamous rash was found, which, in addition to very pronounced polyadenitis, mucous patches on the soft palate, falling off of hair, led to the diagnosis of syphilis. The patient did not remember even having had a sore on the genitals. In agreement with this, no scar could be found as the remains of a primary sore. After prolonged search, the author found on the left cheek, at the edge of the beard, a solitary scar-like thickening, which looked like a healed hard chancre; on this side of the head also the submaxillary glands were found much swollen. The patient remembered having been cut by the barber shaving him some weeks before, but could give no account of the further course of the disease.—*Medicinische Chirurgische Rundschau.* May 15, 1891.

MEDICAL CHEMISTRY.

DETECTION OF PEANUT OIL IN OLIVE OIL.

Holde, after a careful trial of the various processes for detecting the above adulteration, gives the preference to Renard's, which he describes as follows: Ten grams of the suspected oil, after being saponified, and the fatty acid separated by hydrochloric acid, are dissolved in 90 per cent. of alcohol and precipitated by sugar of lead. The oleate of lead is separated by ether, and the residuum, consisting of palmitic and arachic acids, is decomposed by hydrochloric acid. The fatty acids are dissolved, with the aid of heat, in 50 c. c. of 90 per cent. alcohol. The arachic acid which separates after cooling is filtered out and washed, first with 90 per cent. and afterward with 70 per cent. alcohol. It is then dissolved in hot alcohol and the solution evaporated in a weighed saucer. The weight of the residuum, after taking into account the acid dissolved in the alcohol, equals the whole amount of arachic acid contained in the oil; the melting point of this residuum should be 70° to 71° C. With this process the author has always been successful; but when the olive oil contains not more than 5 to 10 per cent. of peanut oil, it is necessary to make the test with 40 grams of the former, otherwise the melting point of the arachic acid cannot be estimated. Fur-

thermore, the acids which are separated from the lead salt by hydrochloric acid must be recrystallized repeatedly with 90 per cent. alcohol until the melting point ceases to rise, in case the latter is not found to exceed 70° C. at the first estimation. When peanut oil is present, the melting will always be above 70°.—*Chem. Zeit.*

THYMACETIN.

This name is given by Hoffman, of Leipzig, to a derivative of thymol bearing the same relation to the latter which phenacetin does to phenol. Its chemical composition is represented by the following formula, $C_{16}H_{21}NO_2$—that is:

$$C_6H_2.CH_3.C_3H_7\begin{cases} OC_2H_5 \\ NH(C_2H_3O) \end{cases}$$

It is a white, crystalline powder difficultly soluble in alcohol.

Thymacetin has been found to be a prompt remedy in nervous headache, and is also capable of serving as a hypnotic, though it cannot take the place of morphine. The dose for adults is from 4 to 16 gr. Further reports are promised.

EAST INDIAN COCA.

The coca plant has been cultivated for many years in several parts of the Madras Presidency. It grows like a weed, and the yield of cocaine from the leaves is said to be fully equal to that obtained from the American shrub. Should there be, therefore, at any time a larger demand for this alkaloid, it is said that in Southern India there would be no difficulty in obtaining a very large amount of the leaves. The Government botanist, who reports on the matter, is however, doubtful whether it would pay planters to cultivate the plant in any large quantities at present.—*Chem. and Drug.*

IODINE WATER AND ARISTOL AS SURGICAL ANTISEPTICS.

In the *Bonitchnaia Gazeta Botkina*, Nos. 17 and 17, 1891, p. 407, Dr. Tikhon v. Popoff speaks highly of the antiseptic effects of irrigations with iodine water (1 to 10,000) and consecutive powdering with aristol (pure or in the form of a 20 per cent. mixture with boracic acid) in cases of tuberculosis of joints (fungating arthritis, etc.), and bones, callous syphilitic ulcers, simple chronic ulcers, angina Ludovici, phlegmon, furunculosis, wounds of every description, etc. The iodine lotion also gives excellent results in inveterate ozæna. In addition to its powerful antiseptic properties it has a decided astringent and hæmostatic action. Under its use luxuriant and profusely bleeding granulations rapidly assume a normal appearance, cease to bleed, etc. The iodine water likewise speedily checks parenchymatous hæmorrhage from any recent wounds.—*Brit. Med. Jour.*

TO EXTRACT PTOMAINES FROM URINE.

In a note to the Academy of Science, Paris, Mr. A. B. Griffiths presents the following method of extracting ptomaines from urine in certain infectious maladies: "A considerable quantity of urine is alkalinized by the addition of a little carbonate of soda, and mixed afterward with half its volume of ether. After deposit and filtration, the ether is shaken with a solution of tartaric acid, which fixes on the ptomaines to form soluble tartrates. After evaporation of the dissolved ether, the acid tartaric solution is again alkalinized by carbonate of soda and shaken with half its volume of ether. The ether solution is allowed to evaporate spontaneously. The ptomaines remain as residue.

"*a. Scarlet Fever:* The ptomaine thus extracted from urine in case of scarlet fever is a white crystalline substance soluble in water, slightly alkaline. It forms a crystallized chlorhydrate and a chloraurate. Phosphomolybdique acid produces a white yellowish precipitate; phosphotungstic acid gives a white precipitate; picric acid, a yellow precipitate. It is also precipitated by Nessler's solution. The chemical formula of this ptomaine is as follows: $C^5H^{12}AzO^4$.

"Pure cultures of micrococcus scarlatina, gave the same ptomaine by Gauthier's method.

"*b. Diphtheria:* The urine of diphtheritic cases is also a white crystalline substance. It gives a chlorhydrate and a chloraurate. Tannic acid precipitates it yellow; phosphomolybdic, white; picric acid, yellow; and Nessler's solution, brown. Formula: $C^{14}H^{17}Az^2O^6$. The bacillus diphtheria No. 2, Klebs and Lœffler, gives the same ptomaine in pure cultures.

"*c.* In a case of congestion of the kidneys, the parotid glands and the sub-maxillary glands, a ptomaine, crystallizing in prismatic white needles, was formed. Formula: $C^6H^{13}Az^3O^2$. It is very poisonous.

"These ptomaines do not exist in normal urine, and are truly formed in the economy under the influence of the maladies mentioned."

NEWS AND MISCELLANY.

AN INTERNATIONAL CONGRESS ON SYPHILIS AND PROSTITUTION.

The newest suggestion in the way of congresses is that which emanates from Paris. It is proposed to hold in the French Metropolis in 1893 an International Congress composed of medical men, juryists, hygienists, economists, and sociologists, for the study of questions relating to prostitution and the propagation of syphilis. With such a medley of contributors the proceedings ought to prove interesting.—*Med. Press.*

WHAT CONSTITUTES A MAN.

Dr. Lancaster, a London physician and surgeon, recently analyzed a man and gave the results to his class in chemistry. The body operated upon weighed 154.4 pounds. The lecturer exhibited upon the platform 23.1 pounds of carbon, 2.2 pounds of lime, 22.3 ounces of phosphorus, and about one ounce each of sodium, iron, potassium, magnesium, and silicon. Besides this solid residue, Dr. Lancaster estimated that there were 5,595 cubic feet of oxygen, weighing 12.1 pounds; 105,900 cubic feet of nitrogen in the man's body.—*Journal of Balneology.*

"THE DOCTOR WOULD NOT COME."

Many jurymen seem to be under the impression that medical men are paid officers of the State, and bound to go at everybody's or anybody's call. Mr. Braxton Hicks recently very properly explained to such a juryman at an inquest on the body of a child that doctors were not bound to come when called. And he added when people knew this they would be "more likely to send for a medical man when he could do a person good," instead of waiting till death was threatened. The coroner is quite right. This is not a time for medical men to stand upon their rights or to discuss abstract questions. No profession is more ready than ours with its help and its pity by night or day. But there is a limit even to medical kindness, to say nothing of the physical limits of strength and time. A little more consideration for medical men and medical service will be amply recognized by the profession. This will be shown in two ways, as the coroner suggested—in calling them in early to save life, and not merely to certify the cause of death, and in paying them promptly and with some regard for their calling.—*Lancet.*

INTERLEAVED ADVERTISEMENTS.

Doctors are proverbially good natured and long suffering and bear with equanimity impositions that would move any other class of men to rebellion. This is exemplified in the fact that they continue to subscribe for and read medical journals which insult them with interleaved advertisements. Publishers find interleaving profitable and will continue the habit till the subscribers to their publications express their disapprobation in no uncertain manner.

Cannot the reform idea be extended so as to include this improvement in journals? Readers want the advertisements, and the best men read them carefully and find in them many and valuable hints as to new medicaments and instruments, but no man, when reading of an interesting obstetrical operation, wants to be interrupted by a flame-colored leaf telling him of the advantage to be derived from a kidney cure or rheumatic specific. The publishers must live or journals will not exist. It is desirable that they should live and make money, but they can attain both ends without marring the beauty of their productions by the interleaved advertisement.—*West. Med. Rep.*

TEA AS IN CHINA AND JAPAN.

A death this week of a boy, aged 7 years ("shock produced by hot tea without milk") forcibly and sadly emphasizes the particular vice of the ordinary English method of drinking tea. The tea had been left for some time "in the oven to warm," that is to say, it was a strong decoction of tea leaves to which time had been given to extract all the tannin, and which had then been rewarmed. It was then drunk without milk, that is to say, the tannin was not converted into a relatively harmless albuminous tannate by the addition of milk. It is precisely because our English method of "making tea" from such infusion of tannin as well as of theine that tea is so injurious to the digestion, and as in this case, when taken in unusual strength, on an empty stomach, and without milk, becomes an irritant poison. No people who know how to make tea use milk with it—neither the Chinese nor the Japanese; but then the hot water (not boiling!) is poured on to and off the leaves at the table, as soon as the liquor becomes of a pale straw color. The pot is always a small china one, and the hot water kettle is brought alongside it on to table. Half a minute suffices for the first infusion. It is a very grateful and refreshing beverage this "honorable tea" which one sips at fre-

quent intervals in the far East; but of course it would be, and is, insipid and not worth drinking if its flavor be drowned by sugar and milk. No people in the world drink so much tea or so often as the Japanese, and Europeans in Japan easily fall into the same habit. No word is ever heard of its being injurious or a source of indigestion, but that is because they take care not to extract the tannin from the tea leaves, and we take great care to do so. That is why we say persons who live on tea and bread-and-butter have weak digestions, and why this poor boy was poisoned.—*Brit. Med. Jour.*

CREMATION, BURIAL AND EXHUMATION.

In *The Lancet* of January 2, page 42, in an annotation on burial reform and its legal regulations, it was observed that "no other method can ever so fully satisfy the possible needs of a criminal investigation as that which allows the exhumation of the body." While fully maintaining the soundness of this position, it is at the same time most important that this should not be made any excuse for haste, carelessness, or an undue desire to oblige in the giving of a certificate of death on the part of medical practitioners, in registering a death on the part of registrars, or in burying without a burial order on the part of cemetery or churchyard officials. For although the body may remain in the ground and be available for exhumation, post-mortem examination, and chemical analysis, all these may be in vain, and a medical certificate given with an imperfect knowledge of all the circumstances surrounding the last illness, followed by a hasty burial, may defeat justice as completely as if the body had been cremated. This must be rendered more probable if burial reform grows in favor as it is hoped it will. For although much valuable information may be obtained by an examination of bodies even in an advanced state of decomposition, and though toxicological science may detect poison after months and even years of burial, still pathological and chemical research both have their limits, and some poisons could be named which would defy detection even within a short period after death. In every or any case of death from poison or other unfair means, it is much better to detect this before rather than after the body has been committed to the grave. The two following cases will prove the truth of the preceding remarks. For obvious reasons the names of persons and localities are suppressed. Some years ago a man went to his work in his usual health, at his usual hour one morning. He returned to his dinner, after eating which he was seized with convulsions and died. A surgeon examined the body and gave a certificate, and the body was buried. Some weeks after suspicious circumstances came to the knowledge of another surgeon, who succeeded in causing the exhumation of the body, its examination, and the despatch of the viscera to an eminent analytical chemist. Strychnine was indicated by the symptoms as the poison which had caused death, but it could not be detected even by the most refined processes adopted by the analyst first employed, nor by a second one to whom the viscera were also sent. The bodies of two children whose deaths occurred previously were also exhumed, but the chemical inspection of the viscera was also negative. A person was put upon trial for murder, but although the case was a most suspicious one, the non-detection of poison was fatal to a conviction, and the prisoner was acquitted. In the second case a child died under circumstances which aroused the suspicions of one of the two medical attendants, who were respectively a retiring and a remaining partner. The former was dissatisfied with the mother's manner, and puzzled with the symptoms, which were not those of any natural form of disease incidental to childhood. A second child died very soon after. and a certificate was given and the body buried. Later on the husband and father was taken seriously ill with similar symptoms but fortunately was saved by copious vomiting and violent walking exercise. Lastly the wife and mother was also suddenly seized with similar symptoms, and arrested on a charge of attempted suicide. Then followed a full inquiry, with examination of the two bodies and the detection of morphia. The prosecution had to contend with the difficulties which will always arise where a charge of murder is preferred some time after the death of the victim, and when the circumstances are not fresh in the memories of the various witnesses, and the woman was acquitted. Still greater is the difficulty when a medical witness has to avow having given a certificate of the cause of death which was palpably incorrect, when those who make the necropsy have to deal with a decomposed corpse, and when the analyst endeavors to detect a vegetable alkaloid under circumstances very unfavorable to its discovery.—*Lancet.*

Telephonic—"Is this 257? Oh! doctor, my husband wants to go down to business, but I told him this weather is only fit for beasts! Won't *you* come over and persuade him to stay indoors?"—*Yale Record.*

SEDATIVE. ANODYNE.

EFFERVESCENT
BROMO
(WARNER & CO.)
SODA.

Caffein 1 Grain, Bromide Soda 30 Grains in each heaping teaspoonful.

USEFUL IN

Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness, and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromide Soda 30 grains, and Caffein 1 grain, in half a glass of water, to be repeated once after an interval of 30 minutes, if necessary.

ANTI-RHEUMATIC. SEDATIVE.

EFFERVESCENT.
BROMO
(WARNER & CO.)
LITHIA.

EACH DESSERTSPOONFUL CONTAINS:
℞ Salicylate Lith a 10 grains, and Bromide Soda 10 grains.

A REMEDY IN THE TREATMENT OF
RHEUMATISM, GOUTY DIATHESIS, ETC.

Dr. A. Garrod, the well-known English authority on Gout, who was the first physician to introduce the Lithia Salts in the treatment of Gouty Diathesis, states that their action is materially increased by being administered in a *freely diluted form.*

This effervescing salt of Lithia furnishes an easy and elegant way of applying Dr. Garrod's methods.

INGLUVIN

A SPECIFIC FOR VOMITING IN PREGNANCY.
A POWDER:—PRESCRIBED IN THE SAME MANNER, DOSES & COMBINATION AS PEPSIN
In Doses of from 10 to 20 Grains,
AND A POTENT AND RELIABLE REMEDY FOR THE CURE OF
Marasmus, Cholera Infantum, Indigestion, Dyspepsia and Sick Stomach,
caused from debility of that organ. It is superior to the Pepsin preparations, since it acts with more certainty, and effects cures where they fail.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

ESTABLISHED 1830.

CLINICAL LECTURE.

THE TREATMENT OF SEVERE PHLEGMONS.*

By PROFESSOR HELFERICH,
OF GREIFSWALD, GERMANY.

Gentlemen: As far as we are compelled to resort to surgical interference, it is always a chief aim to avoid any possible infection of the wound. Further, in all cases of infectious or septic inflammation, it is our one endeavor to bring the infectious process to an end as speedily as possible.

Without question our knowledge of these subjects has been broadened of late years, and this assertion is amply proven by the single fact that the number of infectious phlegmons, or septic traumatic infections is infinitely less than what it was not many years since. Nevertheless, the number of these cases which, either from neglect or ignorance, have been allowed to run on, and are brought to the attention of the practitioner is still very large. A glance at recent medical literature, especially as set forth in medical journals, will show that in spite of the many recent advances in modern surgery, the therapy of this subject has been but little studied and has not received the attention it has merited. For this reason I feel justified in devoting this lecture to a consideration of so all-important a subject, trusting only that the experiences here set forth may be a guide and a help to you, and perhaps ultimately stimulate you to individual researches.

My own experiences with the subject have been very extended. It has been a peculiarity of my experiences in Greifswald that an unusual number of cases of seven phlegmonous processes, as well as eight cases of acute purulent infiltration, have come under my care—far more than I ever saw while either as assistant at the Leipzig Hospital, or occurring among the large amount of material that came under my care in the Polyclinic of Munich. It may be that the impoverished condition of the people is a factor in this peculiarity, but apart from this it is undoubtedly a fact that these as well as analogous infectious processes — such as acute purulent osteomyelitis — occur with much greater frequency here than in the other places mentioned. Under these circumstances the treatment of cases of severer phlegmonous inflammations, although different in individual cases, must still be regarded as more or less typical, since certain rules have not only always been adhered to, but have as well been always indicated.

In the closer consideration of this subject, we will take, for instance, cases of phlegmonous inflammation of the hand and forearm, which have been caused, we will say, by an insignificant puncture wound of the little finger, and which has rapidly spread. Immediately after the admission of such a case, its only place is the operating table.

If we are right in following the old rule, viz., that an incarcerated hernia demands immediate treatment, and a release of the incarcerated bowel, then such an action as immediate surgical interference in acute phlegmonous processes is most assuredly indicated, There is absolutely no need of putting such a patient to bed upon admission to the hospital, even though his arm be well bandaged and supported. A spreading of the infectious process, together with the continuance of the absorption of the poisonous, fever-producing products of the septic inflammation would only be the result, not only injuring the general condition of the patient and jeopardizing the life of the tissues, but also increasing the risk of a subsequent, and very possible lethal termination of the disease. An immediate operation is, therefore, the only rational indication in such cases, and as soon as the case has been satisfactorily diagnosed, preparations for the operation should be at once commenced.

*Translated from the *Berliner Klinische Wochenschrift.*

The patient should be first bathed, if possible, and then placed upon the operating table in a convenient position. It will be of value, also, to see that the arm is accessible both from the dorsal and the inner side. For my part I make it a practice to place the entire arm upon a small table placed at the side of the one upon which the patient lies. This arrangement I have found to be most convenient, and greatly facilitating the operation. After the patient has been thoroughly anæsthetized, the skin of the arm and fingers is carefully washed and scrubbed with hot soap and water, and shaved, and finally rendered antiseptic by the use of disinfectants. The arm is then elevated until it is perpendicular, and without any further manipulation, or stroking, an Esmarch's rubber is placed around the arm below the shoulder, and the limb thus rendered bloodless.

There is, perhaps, no other operation, in my opinion, in which I consider a bloodless condition of the limb of such importance. If this condition of bloodlessness is considered indispensable in the operation of sequestrotomy in order to be able to trace the course of small fistulæ, I would also declare it indispensable in this operation where an exact knowledge of the extent of the spread of the suppurative elements, as well as the tracing of small isolated foci of suppuration, is of the greatest possible importance. Even œdematous swellings of the upper half of the arm, do not restrain me from the applications of the Esmarch's tube or bandage. I have never observed any harm to follow its use. If the phlegmonous process has reached as far as the shoulder, we have, in the majority of cases, a condition in which the conservative surgeon can generally be of no value, and in which the question is either one of exarticulation or amputation.

We now may proceed to make our initial incision, which should be done after making the arm tense. As as illustration we will presume, as I have previously stated, that the initial point of infection is upon the fifth finger. The incision should begin at the point of infection, and should be continued in the direction of the length of the finger, rather to one side of the flexor tendons. An assistant should then pull the edges of the wound apart with small hooks, as otherwise the field of the operation can not be seen sufficiently clearly. If the pus channel within or close to the sheath of the tendon, it will be well to insert a sound or grooved director, and to increase the incision by cautiously cutting down on this with the knife or scissors. In this way the incision is gradually enlarged until it reaches the palmar surface of the hand, through which it is continued, care being taken to avoid any injury to the tendons, nerves, and larger vessels. The *ligamentum carpi volare* is then reached and cut through. In phlegmonous processes originating in the little finger, the suppurative process will be found to be located on the ulnar side of the common flexors, and the incision should be continued in this direction; which, if we are dealing with an infectious process originating on or near the thumb, we will find that the suppuration will be confined nearer to the radical side of the forearm, and our incision should be enlarged in this direction.

Often we will find incapsulated foci of suppuration between the muscles, and perhaps even under the deep common flexor of the fingers so that the interosseal fascia will have to be opened. In all cases the incision should be extended up the arm until both ocular examination and palpation convince us that healthy tissue has been reached.

The entire operation should be performed with great nicety, care being taken not to injure the edges of the wound, and also not in any way to injure or tear the infected tissues, and doing so to increase the liability to a continuance of the septic process. When necessary other incisions should be added to the main incision, and these may be located either on the palmar or dorsal surface of the hand, as the case indicates.

The goal we are striving for in the performance of this operation is complete eradication of the phlegmonous process by the single operation, so that no subsequent surgical procedure may be necessary. For years past, in discussing these subjects before my students, I have made use of the following expression: "Our honor as physicians demands that we should cause a stoppage of the infectious process by a single operation." In fact, our honor is in the maintenance of our patients' best good, and to this end it is by no means immaterial whether they be kept under the influence of such a poisonous process for a long or short time. On the contrary the local as well as general condition of the patient is endangered more and more every hour the infectious process continues.

If the operation as described by me is successful—and it fortunately usually is—the patient will be free from fever and convalescent within a very few days, or at the most three days.

I am a strong opponent to any other treatment of these septic processes. I have never seen good results from a simple puncture of

the infected parts, and small incisions with drainage accomplished but little more. Regarding drainage, it is in many cases absolutely prejudicial, since the rubber drainage through erosion, may lead to arterial hæmorrhages, the opening of tendon sheaths, and, indeed, to a serious impairment of the joints of the hand. The only place I think the use of the drainage tube is at all admissible is from the highest point of the incision if on the flexor side of the fore-arm and extending nearly to the elbow, and protruding some distance further down.

The operation having been completed, we now come to a consideration of the traumatism thus produced. For some time past *I have omitted all disinfection of the wound.* I was first awakened to the possible value of this omission on purely theoretical grounds, and have since had ample opportunity to demonstrate the correctness of this theory by numerous practical tests. Why should we wish to injure or even perhaps cauterize the tissues, when upon the recovery of their strength and health rests the entire success of our operation? Why should we seek to further injure the already severely poisoned organism by causing the absorption of disinfectants? So, after the operation I limit myself to a gentle douching and careful washing of the parts with a six per cent. sterilized solution of salt and water; and this only in order to completely remove all blood and matter from the wound. By the adoption of this precaution the probabilities for the ultimate success of the operation are greatly enhanced. Further grounds for this method of treatment tending to show the inutility of the antiseptic treatment of the wounds resulting from the operation for phlegmonous processes, I do not think are either necessary or called for. Yet we know from the writings of many eminent surgeons and investigators that the action of disinfectants upon the kidneys can be a most unfavorable one and maintenance of a healthy and active condition of the kidneys is of greatest importance in cases of septic infection. The local action of disinfecting douches in insufficient operations is entirely illusionary; in thorough and extended operations it is entirely unnecessary.

Now comes the bandage, which should be applied if possible while the patient is under the influence of the anæsthetic, and after all the visible vessels have been tied. This consists, primarily of the introduction of one large or several smaller pieces of iodoform gauze in the wound, so that all crevices and cavities are covered by a layer of the gauze. This application of the iodoform gauze should be executed with great care and nicety. A large quantity of the gauze is not required—one layer over the tissues being amply sufficient. By this the superficial healing of the wound is guarded against, and free exit of secretions from the deeper portions is assured. Sterilized gauze would answer the same purpose if it would keep in place and unchanged, but in these very particulars iodoform gauze is vastly superior, since it will keep in place, while the superficial dressing and bandage can be daily changed. In about a week this gauze will become loosened and as a rule under it will be found normal granulating surfaces.

The subsequent indications for treatment are but simple. Over the superficial wound, and surrounding the limb, should be applied a moist warm dressing, the dressing being preferably moistened with Thiersch's solution of salicylic and boric acid (1.0 to 15.0—500.0 grammes). This dressing will prevent the decomposition of the secretions it absorbs.

Over this should come "protective" or gutta-percha paper, and then the limb carefully placed in a well padded arm rest or splint in a natural and comfortable position.

The constricting Esmarch's bandage having now been removed, the arm is held in an almost vertical position in order to avoid possible hæmorrhage,and to favor the recovery of the tissues. After three or four hours the arm is lowered to a moderately elevated position upon a pillow. The dressings should be removed the next day, but the iodoform gauze not disturbed.

If such a treatment is strictly followed, healing will result more rapidly than when treated by any other method. The wound will develop normal granulations, and the necrotic parts will be thrown off.

It is of the greatest importance to the definite result of the healing that this condition of the wound shall be brought about as speedily as possible. As soon as the entire wound is evenly covered with granulations, or the small necrotic portions can be removed by excisions, it can be regarded as an aseptic wound. Nothing stands in the way of its secondary healing, on the contrary it offers the best possible promises for an ultimate complete restoration of all the functions of the hand and arm.

Concerning the importance of and the method of making the suture of the secondary wound in these cases, I have already spoken in the *Münchener Med. Wochenschrift,* some time since. Its successful performance in healing wounds following phlegmonous infections is a point of great importance, and one upon

which the final result of operation greatly depends.

It will be self-evident from examination, as to what degree a freshening of the edges of the superficial wound will be necessary in order to insure a good union. The granulations should be removed to a great extent with the handle of the scalpel, in order to insure a healing of the wound without an intervening cicatricial tissue. The more thorough the preparation of the edges of the skin, and of the wound itself, the better. This not alone for the sake of rapid healing, but because every cicatrix, apart from its tendency to contract, forms a vulnerable point which might very probably lead later to an erosion with subsequent reinfection. A quick healing might also be obtainable by transplantation, but unless absolutely necessary this should not be done, as the results offered by it relative to the ultimate motility and use of the limb are not nearly as good as those held forth by a healing by first intention.

The edges of the wound are now cautiously brought together by sutures, and small drains may be placed in the deepest portions. Tension should be avoided as much as possible, as the stitches easily cut through the skin. It is well, if necessary, to reinforce the stitches with strips of adhesive plaster,

The rapid healing of this wound is now of great importance, so that a mobilization of the hand and fingers may be commenced early. For this latter purpose all the modern aids of value can be applied, including passive movements, bathing, active movements in the water bath, massage, electricity, compresses and fixation in different positions at night. A very valuable addition to our armamentarium in this respect, is the apparatus designed by Dr. Krukenberg, which consists in the application of a pendulum to stimulate and restore the motility of the hands and fingers. Caps or rings are placed upon the fingers, to which a pendulum is attached, and the latter set in motion. Apart from the direct utility of the apparatus, which I most heartily recommend, it will prove a most agreeable occupation to the patient, who can thus be busied in restoring the motion of the joints of hand and fingers. I know of no other procedure so effective and valuable, and I use the apparatus constantly in various modified forms in my polyclinic.

I would have been pleased to show you today one of my most recent cases of phlegmonous infection, but, unfortunately, the patient, who is a man, is compelled to be at work, and so I must content myself in calling your attention to these photographs of his hand. (Demonstration.)

Apart from a slight contraction of the little finger, the flexor tendons of which were necrotic, the hands and fingers are perfectly normal, both in appearance and motility. The patient, a working man, 32 years old, was admitted to this clinic on the sixth of March, and operated upon at once. The phlegmon had appeared after a slight injury to the little finger of the right hand, which had occurred on Feb. 27th. On admittance the hand and fore-arm up to the upper third, were greatly swollen and tense; the axillary glands were as large as hazel-nuts, the temperature 39.10 C. The patient was immediately anæsthetized and the arm rendered bloodless. The skin was freely divided from the seat of the injury to some distance beyond the volar carpal ligament, the latter being cut through. The incision was made on the ulnar side of the hand and arm, and care was taken not to injure the ulnar nerve. The flexor tendon of the little finger was found to be necrotic. Pus pockets were found between the muscles, and on the inter-osseous ligament, as far up as the upper half of the fore-arm. After complete division of the skin over the infected parts, they were washed with the sterilized salt and water solution (6 per cent.); then a dressing as previously described was applied. On March 7, the day after the operation, the temperature had fallen to 37.3° C. in the morning, and 39.5° C. at night. March 8, temperature 37.6° in the morning, and 38.8° at night. After March 9, there was no fever.

On March 18, the granulations were scraped off and the wound entirely closed, except at one point on the little finger. Healing occurred quickly and good movement was obtained. The patient was discharged on May 4.

The patient was again seen on August 24, and both the appearance of the hand and fingers, and the motion and strength found to be entirely normal. There were no erosions. It will now be very evident to you why I, in the treatment of these cases, have laid such stress upon the quickest possible production of an aseptic wound, as the key to ultimate success, functionally and otherwise.

Various questions now arise. Is it possible to obtain absolute asepsis at a single sitting, and at once to proceed to close the wound? This, without doubt would be the ideal procedure which *a priori* we are striving after, but in practice can the desired end be thus accomplished? I would acknowledge the possibility of this being true in cer-

tain cases, but believe that in the majority the results would be most disastrous, not only locally but generally, and, therefore, I cannot look upon such a method as either rational or justifiable. The *non nocere* is more important in this instance, in the majority of cases, than the dazzling promises of uncertain results in a few.

All that has been said in this lecture can be applied to the treatment of analogous phlegmonous processes in other parts of the body. On the subject of operations for acute purulent infiltration, I would like to add a few words. In these cases only the most energetic treatment can save, and the question is not one of saving an extremity, but of saving life. I have been able to save some cases in which the septic process was already very far advanced.

A clearer idea may perhaps be obtained by the recital of a case of a boy, which was, as far as the local condition was concerned, the most severe I have ever met, and I take pleasure in showing you photographs of the same. This infiltration extended from the calf of the leg to the pelvis. A portion of thigh seemed almost gangrenous. I made several longitudinal incisions, about an inch and a half apart from each other, and thus forming strips of skin which subsequently contracted, and removed a large amount of pus and cellular tissue infiltrated with pus. The boy made a good recovery, although transplantation was necessary in order to effect a complete closure of the wounds. The boy, now 16 years of age, is entirely well and strong.

I might quote you many similar cases which resulted favorably—others again in which there was a lethal ending in spite of our most energetic treatment.

The prognosis of severe local septic process does not depend solely upon the age or strength of the patient. It is far more unfavorable if we are dealing with heavy drinkers, or if the kidneys are in any way diseased.

Nevertheless, the surgical treatment in all cases of phlegmon constitutes our most valuable treatment of this disease, and I shall be pleased and satisfied if this lecture will tend to stimulate you to study in this direction, or aid you in the successful treatment of such septic processes.

The number of micro-organisms in a fluid, milk for instance, may be greatly diminished by subjecting the same to centrifugal action. Some germs are more readily removed than others.

CLINICAL FEATURES OF THE PRESENT EPIDEMIC OF INFLUENZA.

By JAS. M. ANDERS, M.D.,
PROFESSOR OF MEDICINE, MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA.

Gentlemen: I desire to call your attention this morning to some cases illustrating different forms of influenza. The cases will also show some of the complications of this disease.

Case I. Male, 35 years of age; born in Ireland, occupation fireman, was admitted on the 29th of December last. Family history is as follows: Father died of paralysis; mother living and healthy, brothers and sister living and healthy. He had all the diseases of childhood; fair health previous to last illness; has been a hard drinker. Six weeks ago the onset of the present attack occurred, when he thought he had taken a heavy cold. He began to cough and sneeze a great deal; shortly after his knees became painful and swollen, the right ankle was also somewhat painful and slightly swollen. He had pains at the same time in the head, back, and left side around the heart. His cough became frequent, dry, and he expectorated very little.

Now, gentlemen, from the history of this patient there is no doubt that the man had an attack of influenza, which has developed very interesting complications. The first of the latter to which I would like to call your attention is the condition of the joints. He had, as you will recall, pains and slight swelling of knees and one of the ankle-joint. This you will see is a picture resembling closely cases of rheumatism. But, gentlemen, in cases of influenza we encounter conditions exactly similar to the one we have met with here. In these instances you will find very little, if any, disposition of the trouble to change from one joint to another, and, as a rule, no cardiac complications, which occur so frequently in articular rheumatism. We must bear in mind, however, that we do meet with cases, and not a few, in which there may or may not be joint symptoms, and yet, we may have cardiac murmurs present. This is not due to valvalitis, but due to an altered condition of the blood. The next interesting complication in this case, and one which I have very frequently met with during the present epidemic, is acute pharyngitis. In some cases, both tonsils and the palatine arches are affected, and are the seat of follicular ulcers.

The temperature it is interesting to note, notwithstanding these two complications of

considerably severity, has not been much elevated. That is one of the peculiarities of the prevailing epidemic, viz., a low temperature. In young persons who were previously in good condition, the temperature did become elevated, but very often not to any great extent, in spite of several forms of complications.

Case II. The next patient is a female, born in Germany, occupation, domestic. Her father and mother died during her childhood; one brother died of phthisis and one of dropsy. She has had the diseases of childhood. Seventeen years ago the patient had the same condition as at present, she thinks. She is married, has two children, and has had no miscarriages; menstruates regularly. One week before admission she had pain in head, back, and limbs; stools yellow in color. Temperature on date of admission 102⅘°, afterward 103⅘°, subject, as you notice on this chart, to marked irregularity. The pulse was rapid, respirations were rapid and decidedly panting in character; eyes bright; pupils dilated; tongue coated with a heavy white fur; tenderness over abdomen, but no distension; cough, dry, hacking; expression, cyanotic; consolidation at both bases. Second day after admission; sputum rusty, pain and tenderness in abdomen still, some distension; consolidation at base of lungs; urine showed hyaline casts with considerable albumen; the bowels were moved several times within the twenty-four hours, stools thin, ochre in color, offensive odor.

In order to go as briefly as possible over the history of this case, we may mention, at once, that it presents three features of decided interest.

In the first place nearly all her local symptoms were referable to the abdomen. She very soon, however, developed a severe complication of the lungs, namely, lobar pneumonia. Then she also had renal symptoms, which are of decided interest. Now, from the history of this case, and from an examination of her urine, we may justly conclude that this patient was suffering, before the date of the onset of her influenza, from a latent form of Bright's disease; for, while we do find albumen, epithelial and hyaline casts in influenza, we do not find granular casts, as a rule. But the point to be borne in mind is that when a subject of this sort is attacked with influenza, all the former minor symptoms become very much intensified, and you are apt to have very severe complication attending the attack of "grip."

We did not think this patient would progress anything like as well as she has. Indeed, the prognosis of all cases of this sort, in which you have associated latent Bright's disease and lobar pneumonia as a complication, more especially when the latter is double, is highly unfavorable. Now, we are not quite sure whether this woman had Bright's disease previous to the onset of this trouble; I have given you my reasons for thinking so. There are cases in which there had been no previous trouble with the kidneys, and yet well marked renal symptoms, as in this case, have developed during the attack. In such cases the urine becomes normal as soon as the patients have fully convalesced.

I wish to refer to one other point; from the history you will notice that she had many symptoms of typhoid fever. Oft-times at the commencement of influenza, you may be puzzled to decide whether you have a case of typhoid fever or influenza to deal with. In all cases where you have symptoms that excite suspicion of typhoid, as we have here, you should be on the look-out for the more characteristic symptoms of typhoid fever. As long, however, as you do not have swelling of spleen or the characteristic eruption you will not be justified in making a diagnosis of typhoid fever, however closely the symptoms simulate those of the latter disease.

This woman still has a great deal of tenderness over the abdomen, and this reminds me that I should speak of another interesting feature in connection with her case. You may touch her almost anywhere and she gives signs of pain. Now, what does this mean? Hyperthesia of the skin, another interesting complication of the influenza. You do not meet with it very frequently, but when you do you have a very valuable diagnostic symptom.

Case III. The next patient that I wish to bring to your notice is one that also illustrates that grave lung complication, namely, lobar pneumonia, but there are other features of great interest not presented by Case II.

The patient's initials are J. C., born in England; no occupation; weight 135. Mother died of phthisis, father of paralysis. Had diseases of childhood, and four years ago had rheumatism.

Three weeks ago had sick stomach, pain in back, stitch in left side, legs swollen; was not confined to bed. On admission had consolidation of most of left lung; cough troublesome, breathing labored, somewhat panting, temperature 101°; heart's action frequent, weak and irregular, and presence of mitral systolic murmur. Now, the history of this case up to January

1st was similar to the one which has just been taken out. We had here the back-ache, fever, and note especially what we have had in all the cases, pain in left side around the heart. In almost every case that I have met with during the present epidemic, this symptom, namely, the stitching, burning pain has been more marked on the left side than on the right. You will also notice that this patient developed lobar pneumonia at the end of one week. And here let me lay stress on the fact that lobar pneumonia is a complication which is very apt to come on late in the disease, most frequently during convalescence.

Now in connection with this case of lobar pneumonia, I wish to call your attention more especially to the condition of the heart. Remember, from the man's history, we learned that he had acute rheumatism four years ago; he also gives a syphilitic history. Under these circumstances we would be likely to find chronic valvular disease existing. Doubtless, this was true of this young man before he developed influenza, because we have here on palpation a decided thrill, and on auscultation, a murmur which is systolic in rhythm and harsh. We cannot outline the heart very well by percussion on account of the dullness to which the consolidation gives rise, but we have sufficient physical signs to enable us to make the diagnosis of chronic valvular disease. It is not strange then that when admitted he should have had a very feeble, rapid pulse; it is not strange that he should have developed swelling of the feet the moment he was stricken with the influenza. Even where perfect compensation has existed before the onset of influenza in valvular disease, you are very apt to have dilatation of the right side, followed by swelling of the feet, and other evidences of failure of compensation. This ensuing case then, illustrates the fact that in persons suffering from chronic valvular disease of the heart we see grave forms of influenza attended by the graver kinds of complications, namely, broken compensation, lobar pneumonia, etc. It is well known that where you have right-sided dilatation and the patient becomes affected with influenza, you have a very grave form of the disease, but I do not know it to be stated in text-books that where you have chronic valvular disease, dilatation and dropsy are apt to follow. The heart should be carefully attended to from the onset of the disease.

Case IV. J. W., aged fifty-four, born in America; occupation laborer, admitted to the male medical wards of the Philadelphia Hospital January 6th, 1892. Family history negative. When quite a boy while skating was precipitated into the water through an air hole; following this he had articular rheumatism which has made him a cripple for life.

Present illness began with severe pain in the head, limbs, back, and chest, especially, however, in the head, and in the right shoulder, and again in the region of the heart. On examination at time of admission there was found consolidation of right apex; expectoration thick, yellow in color, not rusty; cough troublesome. This man we learn, began with cough accompanied with slight expectoration, cough loud and ringing as we find it in many cases of influenza. In many instances of influenza, especially at the beginning, the severe paroxysms of coughing much resembled whooping cough.

But there is another set of causes in which the initial condition of the tubes and larynx is a state of intense irritation, followed by a genuine bronchitis. Since we have in this case, in addition to a small area of consolidation, the history of bronchitis, from the beginning of the attack, lobular and catarrhal pneumonia may safely be diagnosticated.

Some contend that you have first collapse of a portion of the lung, with congestion around the seat of the collapse which leads to consolidation. The cause of this collapse and congestion it is contended is enlargement of the bronchial or tracheal glands or both, associated with marked disturbance of the great nervous tract at the root of the lung.

Few men in the profession are, perhaps, familiar with the fact that if we make percussion over the four upper dorsal vertebræ you get normally tympanitic or tubular resonances, while below this point, i. e., the fourth dorsal, you get a more nearly normal resonance. When you have a case of inflammation of the bronchial and tracheal glands you have a decided dullness down to the point at which the bronchi bifurcate, the lower edge of the fourth dorsal. The complication lobular pneumonia is more frequently met with in influenza than lobar pneumonia.

Case V. I will simply relate to you very briefly the notes and show you the temperature chart of this patient, without troubling you with the physical signs.

The patient was convalescent, but exposed himself on the night of January 1st, this was followed by pain in the back, head and chest a severe rigor, cough and greenish-white sputum at first, afterwards somewhat rusty. Consolidation of the base of the lung and apex of the other side was noted on admission. This is a very interesting condition. This is also a case of lobar pneumonia. From the temperature chart you will observe the

temperature reached 104°, and having kept at that height for five or six days we may now soon look for a crisis. This case also illustrates the fact that the consolidations are apt to be double in influenza, and bear in mind too, if you please, that this case developed lobar pneumonia three weeks after the onset of the influenza.

Let me briefly in conclusion call your attention to the treatment of this disease, influenza. In the first place we hear a great deal about arranging all the cases into two or three large categories or types. Now, the present epidemic better than the one that prevailed two years ago shows how impracticable this proposition really is. There are too many cases in which the types merge into one another. It is far better to arrange them into classes according to the severity of the cases, according to Wilson's suggestion. There is no doubt that there is a very large class of cases which never betake themselves to bed; on the other hand there is a middle class in which the temperature is pretty high, the patient betakes himself to bed and remains there from three to five days. Then you have the graver form of the trouble in which you have the serious complications arising.

The milder cases require little or no treatment. Let the patient keep warm, taking possibly quinine in moderate doses. Tell them to abstain from meats. Never give hot drinks except on the first day. If you fail to abort the attack they increase the pain, and more especially the headache. Give cooling drinks.

The second class of cases are those who have considerable fever with catarrh of the bronchia, or of the stomach, or possibly other organs. Now, these require a special form of treatment; not very often are we required to use antipyretics with the object of reducing the temperature. We have, however, a good remedy in quinine. We give as much as 12 to 16 grs. a day. If there be headache and lumbar pain you may combine about 3 grs. of phenacetine in the dose. Treat the catarrhal element actively according to general principles.

We have now to consider the treatment of the graver forms of this disease. We must here, at once, institute the antifebrile regimé. The diet should be milk, beef tea, animal broths, etc., given at stated times. The feeding is very important in these cases, because there is a longer temperature curve and great physical depression. Give strychnine and alcohol, with quinine to support the system, avoiding depressants. Morphine for the pains. Treat the complications as you would if they were under other conditions. I want to call your attention to a few of the unusual features of the present epidemic. And first, it is to be noted that the temperature curve is unlike that met with in former epidemics, in some particulars. Thus, I have seen not a few cases that began with a temperature of 103° or even 104° F., which almost at once declined steadily to the normal, to remain so, the whole attack lasting 2 or 3 days. Apparently little or no local catarrhal conditions developed in these cases.

We have a temperature curve of influenza noted by DaCosta, which for a day or two is high, then a steep decline, a rise again to almost the former height, then following this an irregular temperature tending back to the normal. This is rather unusual. We have also a temperature which is much like that of typhoid fever. Now I find that in the cases, like the one that has just gone out, with a temperature chart resembling the typhoid curve, one or more complications present, such as lobar pneumonia, lobular pneumonia, enteritis, etc., which would explain the continuance of the high temperature and cause it to resemble typhoid.

The throat complications are numerous this year, including follicular and necrotic tonsillitis. We see in the present epidemic of influenza, suffocative attacks, and we also see a great number of cases of active bronchitis and superficial laryngitis. Aural troubles are also common, being secondary to the throat troubles.

Lobar pneumonia seems to be entirely independent of the bronchitis though very frequent. Lobular pneumonia is more frequently seen still. The latter complication is often preceded by an active form of congestion.

I would also call your attention to the nervous phenomena of the disease as compared with those seen during the epidemic that occurred two years ago. There is no doubt in my mind that we have more tendency to depression of spirit, more irritability of temper. We see during the present epidemic in a greater proportion of cases, a mild, and not rarely an active form of delirium. And again, I have noticed that convulsions occur. This was seen by me in two instances, and other physicians have met with about the same proportion of cases. Vertigo has been present in nearly all of my cases. In the present epidemic children were numbered among the victims from the first, while in the former, children were stricken down toward the close. Much more might be stated on this head, but as the hour has passed, time will not permit.

COMMUNICATIONS.

EPISCLERITIS.

By ARTHUR D. MANSFIELD, M. D.,
ASSISTANT SURGEON PRESBYTERIAN EYE, EAR AND THROAT CHARITY HOSPITAL,
BALTIMORE, MD.

Episcleritis is a very rare form of disease, seen only occasionally in our clinics, but when observed presents clear and distinct symptoms.

In most diseases of the eye the diagnosis is absolutely certain and very little, if any, doubt is expressed, and in this form of disease under consideration the diagnosis of scleritis is made upon the objective symptoms and not upon those of a subjective character. We see for ourselves what the trouble is and make the diagnosis perhaps without even asking the patient a single question.

The history of the case is usually one of some length of time in which more or less treatment has been tried, without any appreciable benefit, even perhaps failure and increase of the trouble, in which the pain continues increasing at times, then subsiding somewhat. Some redness and inflammation restricted in area to one of the quadrants of the globe and near the cornea, the inflammation not having the general appearance of ordinary conjunctival inflammations. Pain is experienced by the patient on pressure and there is more or less swelling. So much for the history of the case.

The diagnosis is easily made from the knowledge of the history. The patient has painful vision, photophobia, pain on pressure, when applied directly over the inflamed and swollen area.

The area of inflammation extends over a quarter or less of the superficial area of the eye, or may be located at a very small point, usually, however, it is scattered over a larger area. The inflammation may cause more or less œdema of the conjunctiva immediately over it. Suppuration very rarely occurs, at least I have never seen any case go on to suppuration. Vision is impaired in most of the cases to some extent; the disease is usually restricted to one eye ball; there is always a predisposition to subsequent attacks. It is seen usually in middle adult life between the ages twenty-five and thirty-five. My observations have shown me more cases in the right eye than in the left; however, I see no reason why either eye should be predisposed and hence attach no importance to the fact.

The differential diagnosis is to be made between episcleritis and scleritis, the two being indissolubly bound together, and in reality are only inflammations of contiguous tissues. The differential diagnosis is always difficult, and as there is no necessity of multiplicity of diagnoses the two may as well be considered as the same disease.

To an oculist it is hard to confound anything else with episcleritis, yet we are not all oculists, and to those who are not I make the following differential diagnosis. It may be possible to confound episcleritis with phlyctenular keratitis or phlyctenular conjunctivitis. The episcleritis presents a uniform redness as far as the area extends and seems to be an inflammation of a tissue covered by a healthy tissue, such as a thin mucous membrane like the conjunctiva. And such is the case—the sclera is inflamed and reddened, while the conjunctiva is comparatively speaking very healthy. In episcleritis we have severe pain on pressure, there is swelling and diffuse redness, and it usually occurs in adult life with a history of rheumatism.

In phlyctenular keratitis, the area of redness is localized, is a point to which blood vessels run and from which they ramify in all directions, the phlyctenule or small pustule is located on the edge of the cornea or on the corneal border of the conjunctiva; the phlyctenule is depressed at the top and exudes purulent matter.

The conjunctiva is affected, and the inflammation seems to be superficial, and not covered by any upper tissue, the same painful vision exists, and light is avoided, darkness being a relief to the eye. Like episcleritis the disease occurs in children and not in adults, and usually in children of a strumous diathesis. In phlyctenular keratitis, there is none of that pinkish congestion seen in keratitis (I mean the simple keratitis) which in reality is a congestion of the scleral vessels around the cornea which is so characteristic of keratitis and iritis. Pressure brings no pain in phlyctenular keratitis, though the patient may suffer pain locally.

These in brief are the main points of differential diagnosis between episcleritis and phlyctenular keratitis. There are other forms of disease which might be confounded with episcleritis.

The Ætiology of Episcleritis: It is a very well-known fact in general clinical medicine that the rheumatic poison has a peculiar liking for and tendency to invade fibrous tissue; we see this in the fact that rheumatism attacks regions mostly composed of fib-

rous tissues, such as the joints. We also know that the sclerotic coat of the eyeball is composed entirely of fibrous tissue, and I have often wondered why we do not see more of episcleritis than we do. Owing to the fact that rheumatism exists in so many cases, and is so severe in a majority, why does the inflammatory virus, if you will, not attack the sclera more often than it does? We see the migratory rheumatism going from joint to joint and having attacked them all still the eye escapes. It is one of those unexplainable occurrences in medicine which we often see and are unable to give any satisfactory explanation.

The causation of the disease then is an infiltration of the fibrous tissue of the sclera, the rheumatic poison setting up an inflammation there very analogous to that in the fibrous tissue of a joint, with the impairment of the function of the part.

The *prognosis* should be given with considerable reservation, though with certainty as to ultimate recovery. The recovery is slow always. As to the repairment of vision, you can always state that vision will be as good afterward as before. In hospital practice where the cases can be watched more closely and longer than in private practice, we have the best results because the patients become less impatient, and the treatment can be instituted with greater precision. It is in the hospital that the methods of treatment become known, and where new remedies can be tried, prognoses modified, and diagnoses learned.

Many remedies are tried and various methods employed. I will endeavor to give summarily and succinctly the experience at the hospital. We have tried the galvanocautery with varying results. Sometimes we have thought good followed, at other times the results have been very indifferent. Astringents externally give very little benefit. Massage has been found to do the most good, accompanied by the internal administration of anti-rheumatic treatment, such as the salicylates, alkaline treatment, salicylate of quinine, potass. iodide, and similar rheumatic treatment. Our results from massage, the salve being the yellow oxide of mercury, grains three, to the drachm, of lanolin or vaseline, have been very gratifying indeed.

The duration of the disease is very variable, so that no definite duration can be stated. My method of treatment is, generally, to use massage at least twice daily, morning and evening, and if this cause too much inflammation and irritation, then lessen the massage to once daily, preferably in the evening before retiring; this external treatment must be accompanied by bold anti-rheumatic treatment, pushing it as far as possible. Episcleritis when so treated will yield as readily as can be expected from a disease so obstinate as the one under consideration.

129 South Broadway.

THE CURE OF THE ALCOHOL DISEASE, FROM A PHYSIOLOGICAL POINT OF VIEW.

By A. ENFIELD, M.D.,
Bedford, Pa.
Member of the Bedford Co. Medical Society, the State Medical Society, and American Medical Association.

The day of medical theories which do not have the basis of established facts to justify them belongs to the past. It has taken ages of observation and investigation by the greatest intellects of the profession to elevate the science of medicine to the high position it now occupies. We live in an age of light and knowledge; an age in which old isms, theories, and fallacies are fast disappearing before the sweeping progress of this century. The past decade has given us the beginning of a new epoch in the science of life. Medical science is now called upon to defend our bodies from the parasites which prey upon us from without, and physiological and chemical researches have taught us the therapeutic application of drugs in the cure of dipsomania and kindred diseases.

The power of self-regeneration is one of the great distinctive properties belonging to all organized living bodies; but the moment we commence to live we begin to die. Molecular change may be increased or retarded by various foods and drugs taken into the system at stated periods. We apply the term hunger to that peculiar want felt by the human system for food, a sensation (when not too long prolonged) by no means disagreeable, and one which is often excited by the sight or smell of a savory dish. It is true the taking of food is influenced in some degree by exercise and habit, as well as by the sense of hunger, and if our systems are not supplied at regular intervals by this nourishment, the sensation of hunger becomes so great that we suffer pain and distress. All the elements necessary to nutrition (except oxygen and light) can be taken into the system by the mouth, and if it were not that there comes a time in the history of every organized body when the tissues fail to appropriate sufficient new material to repair the waste, we would continue to live forever.

Death is, therefore, a physiological necessity. Therefore, there is no such thing as true Euthanasia. But, it is the duty of the physician to secure for man such good health as shall bear him in activity and happiness onward in his course to the goal. Good health and happiness can be secured by living in obedience to the laws of health. When the medical profession succeed in teaching to the world how to live in a proximate, physiological normal condition, then they will have reached the consummation of their calling.

Fifty years ago there was not a Medical College in Europe or America that had a special chair of Neurology, whereas, to-day there is not a school that has not at least one such chair, and some schools have two and even three professors who are giving their undivided time and attention to discoveries and advancements in this important branch of medical science. It is therefore gratifying to the American student of scientific medicine to note the amazing progress that has recently been made in the discovery and cure of nervous diseases, especially by American Neurologists. It was our beloved Rush, who, a century ago, stood as the great pioneer (in advance of all the world) to describe and demonstrate the future of this branch of medical science. It was through men like Rush, Pinell, Brown-Sequard, and others, we learned that insanity is a disease, and not the devil in man, as was generally supposed prior to their time. So that to-day, while medicine is advancing all along the line, in no other department has there been such advancement as in the discovery and treatment of nervous diseases. Advancement has been so rapid in this special department of medicine, that some writers claim that all diseased manifestations are but the result of nervous shock.

Vesalius took his own life in his hands when he was bold enough to sharpen his scalpel for the first dissection on the human body. Galen followed and taught us that the arteries contained blood, and not air, and Harvey showed us how that blood circulated. Jenner, Pasteur, and Koch have been bold enough to transfuse the very elements of chemistry into our blood in order to kill the myriads of germs that infest our organisms and produce disease and death.

By the aid of physiology and chemistry we have used the elements around us to cure disease and prolong life. The great labors of the past are but now beginning to bear their fruits. Alcoholic neuritis is no longer considered a habit, but a disease; as much so, indeed, as insanity.

The old fogy element of the profession may cry out against this new departure in the treatment of a disease; but it cannot stem the tide of scientific progress when the world can see the results and witness the benefits to mankind. The Secum-Lumen, the great light, will open the eyes (of the old fogies) as the noon-day sun opened the eyes of the scoffers of Jenner. If one poor soul can be saved, who dare cry against the cure of a disease that cuts down youth in his vigor, manhood in his glory and strength, and age in his weakness; a disease that has produced more misery, sickness, and death than all other diseases combined?

It is an insult to medical science to say that all the brave and good men who have killed themselves with alcohol and opium did so just from habit. Tell me that all the men of genius whose lives have been wrecked and ruined by these drugs were led to their use by mere accident? Impossible. These men fought like heroes against their disease; and for these diseases they were not responsible.

The day has come in the fullness of time when we can say that this disease that has destroyed so many shall destroy no more. Thousands of human beings are being rescued from the destroying influence of these diseases, and thousands and tens of thousands are yet to be saved from an untimely death. Every new advancement in the science of medicine is met with a storm of opposition. Dipsomania must be recognized as a disease, and not as a habit. Until recently the medical profession have neglected to examine this subject carefully from a physical point of view. They must examine this subject as they examine any other ailment if they wish to reach a satisfactory conclusion.

It is not the intention of this article to begin a controversy with those who honestly believe that inebriety is the result of habit alone. Inebriety is no more due to habit, vice, and sin, than is insanity. If inebriety is a disease, then its cure rests with the physician; if it is wholly a sin, and the man is entirely responsible for his appetite, then his treatment and salvation must come from those who claim it is a habit. A Christian will be a better, a brighter, and a happier Christian if we can remove this appetite for stimulants and give him a healthy stomach. An ounce of cure is worth a pound of prevention, if applied at the proper time. Thousands have been crying for help from this dreadful disease, while theorists have been talking, and preaching, and splitting hairs as to whether it is a moral or physical evil. The word habit, like the word malaria,

is a convenient word with which to explain something we know nothing about. Conversion, change of heart, and the grace of God are great moral helps, but they cannot cure a diseased nervous system, nor a depraved stomach. The moral side of intemperance has been proclaimed for ages, and yet statistics show that inebriety is still on the increase.

On this subject the medical profession have remained silent entirely too long, and have allowed moralists to advance their own views in the matter without any scientific examination of its cause, its nature, its character, or its curability. We must admit that the moral agitation of the subject has done much good, but still there is something wanting. The removal of alcohol does not remove the craving, but rather increases the appetite for it. If we cannot cure the inebriate by the application of drugs scientifically applied, then we shall never be able to cure him by forced abstinence. Public opinion may deny this, and opposition may come from every superstitious person in the land, but that will not frighten the conscientious and progressive physician who has science, experience, and results to support him. He must go patiently on, and look beyond the present opposition of the incredulous and sceptical public, until he has worked out the physiological and pathological condition of the inebriate and restored him to health.

Man is a complex animal, full of variations, and easily influenced by any change in his nerve-centres. His call for stimulants arises from a loss of nutrition to some part of the central system, just as the call for food arises from the same cause. Therefore, it is impossible to cure this morbid craving, which has its seat in the brain, without first removing the cause by appropriate medication. The inebriate may be anxious to quit the use of the stimulant, but the moment he makes the attempt his diseased stomach and brain give notice that they must have something to nourish them.

It is not within the scope of this short article to analyze and examine the many predisposing causes of this disease, such as: heredity and non-heredity, occupation, etc., or we might present many facts and data, that would help to determine this question outside of any personal feelings or opinions we may entertain. There is no subject that should receive more interest or more attention from the profession than this subject of inebriety; and yet in the past we have allowed the laity to do all the thinking, writing and legislating on the subject. It is time we call a halt. The physician is certainly better qualified to investigate the subject, and to pass his judgment on it than those who have never examined it from a scientific point of view. While I have myself devoted years to the special study and treatment of this disease, examined the different systems of treatment (the old and the new), seen successes and failures (under restraint and non-restraint) treated with drugs and without drugs, yet I feel that we have but commenced the study of a disease whose future is full of important information, and of which there is yet much to be learned. We should never allow ourselves to be carried away by the enthusiasm which naturally follows success, nor be discouraged by failures.

The same general principles apply in the treatment of this disease that apply in all chronic nevous diseases. Physical laws and forces are all the same in all individuals. The system broken down by long years of dissipation cannot be relieved by any one drug or combination of drugs alone, but by building up the whole body by special diet, baths, exercise, electricity and good hygienic surroundings. In my hands a combination of drugs has proved most beneficial. Each and every case must have special treatment according to the symptoms manifest. No doubt chloride of gold possesses wonderful alterative properties, and when properly and systematically given in combination with strychnia, atropia, coca, quinine, sulphonal and codeia, they have a tendency to change the habits of the system, and remove the diseased condition of the nerve-centres and allow nature to return to a normal condition. These powerful drugs, when given for a long time, so profoundly influence and build up the nervous system, that the inebriate feels strong and well, and gradually acquires as much repugnance for stimulants as he before had an appetite for them. The treatment breaks or removes the cause of the disease and the inebriate starts in a new career of life.

Of course he may relapse as he may from any other nervous disease. Anything that tends to exhaust the brain, or lower the vital forces, predisposes to a return of the disease.

The individual should live a life free from excitement, annoyance and worry, eat wholesome and substantial food and be constantly under the observation of a physician. Physicians who are familiar with the modern treatment of inebriety do not condemn it; they rightfully refuse to endorse nostrums of which they know nothing. The general practitioner has not the time to devote to the treatment of

these cases. He might as well attempt to treat all his cases of insanity.

Specialists have explored the grounds, investigated the disease and formulated the treatment, and are therefore more competent to handle such cases successfully. Nor is it advisable for the patient to treat himself. Most drugs that are of any value in this disease would prove dangerous in his hands. Besides, the most of the treatment must be given hypodermically, which an unskilled person cannot do.

My reason for dwelling upon the neurological and physiological aspect of this disease is to call the attention of those outside of the medical profession to the great advancements that have been made in this special department of the healing art. The world is too apt to look with disfavor upon any new discovery that is invisible and incomprehensive to the common mind.

They grow wild over the graphophone, the telephone or electric car, but fail to realize the subtle and invisible agent that science is using to cure man. In conclusion we may then state with perfect confidence, that inebriety is a disease and not a habit; and in order to intelligently treat it we must study the nature and character of the disease as it manifests itself in different individuals. We must approach the subject from the physical and not the moral side of case. We must discard any preconceived notions and theories not based upon facts.

The public should not expect them to prove infallible. The best that can be expected of any remedy, is that it will cure the majority of all the patients to whom it is properly administered, and this is just what this modern treatment has done in dispsomania. The deliverance of humanity from this terrible disease will mark a new epoch in the science of medicine.

Facts are the basis of an infinite wisdom that never err. The discovery of every new truth in medical science marks its advancement over past ages. New discoveries spring up with such rapidity, that in the busy routine of professional life we have scarcely time to sift, weigh and analyze their value for good or evil. By the selfishness of our natures we are more prone to condemn and criticise, than to praise.

President Garfield once remarked, that he was always struck with awe when standing near the ocean, and seeing the waves lashed into fury and tossed into spray. Its grandeur would move the soul of the dullest man. But it was not from these billows, but the calm level of the sea from which all heights and depths, lengths and widths are measured And so in the conflicts of science, like the waves of the ocean, one follows the other and after a moment's existence, each one in turn is overwhelmed by the one that follows and both are merged into the past. But human thought differs from the waves of the ocean in this: That we advance and grow in wisdom and knowledge, and that an occasional wave is thrown so far out that it will never recede, so that the eyes of the whole world can behold the progress that has been made to save and prolong human life.

The medical profession is advancing. This century has had its Virchow, Pasteur, Lister, Esmarch, Tait, Billroth, Paget, Koch, Sims, Morton, McDowell, Gross, Pancoast and Agnew.

TWO SUCCESSFUL CASES OF THE CONSERVATIVE CÆSAREAN SECTION.*

By CHAS. JEWETT, M. D.,
BROOKLYN, N. Y.

Case 1. English woman, 32 years of age, 4 feet, 6 inches in height. Health fair with the exception of a chronic nephritis. Pelvis kyphotic. Inlet slightly contracted. Outlet 2¾ inches in the pubo-coccygeal, 2¼ inches in the bisischial diameter. Admitted to the Long Island College Hospital after being several hours in labor. Os externum dilated to the size of a half dollar, and membranes ruptured. Operation Dec. 2, 1891. Pulse 90. A large thin-walled rubber tube used as a provisional uterine ligature. Placental seat under the uterine incision. Hand passes over the left edge of the placenta, and through the membranes. Head extracted with difficulty, and only after relaxing the grasp of the constrictor. Cord clamped at two points with catch forceps and cut between them. Child alive and respiration promptly established. No eventration of the uterus. Placenta and membranes separated by hand, and uterine cavity left undisturbed. Uterus closed with 12 deep silk sutures. Symperitoneal suture of catgut. Almost no handling and no special cleansing of the peritoneum. Abdomen closed with ten silk sutures. Blood loss no greater than in ordinary labor. Tonicity of the uterine muscles apparently unimpaired by the cervical ligature. Good recovery with no sign of sepsis. Abdominal sutures removed on the tenth day. Uterine involution somewhat tardy.

---

* Abstract of paper read before Medical Society, State of New York, Feb. 2, 1892.

Case 2. Was a German immigrant, 20 years of age. She had for a long time been subject to hysterical paroxysms occasionally ending in convulsions and semicoma. Was in bad condition from inanition. Was the subject of a slight broncho-pneumonia at the time of operation, and also of syphilis in the second stage. A most remarkable feature of this case was her temperature record. The thermometer several times before operation, registered 107° F., and once 110°. At the beginning of the operation her temperature was 108⅘° F. The woman was of slender figure, 4 feet 8½ inches in height, and her pelvis extremely flattened. True conjugate 2½ inches. Pubo-coccygeal and bisischial diameters each 2¼ inches. She fell into labor shortly after the sixth month of gestation. Operation about ten hours after the first pains. Waters had drained away but the cervix would barely admit the examining finger. Section complicated with troublesome protrusion of intestines owing to tympanites. Nearly complete escape of the liquor amnii and placenta prævia cæserana. Large thin-walled rubber tube used as a uterine ligature as in the previous case. Placenta separated as before. Child alive and breathing but not viable. Uterus lifted out of the abdomen. Membranes separated with difficulty. Uterus closed with ten deep sutures in 14 minutes from beginning of operation. Decidua not included in the sutures. Sym-peritoneal sutures of silk. No flushing and little cleansing of the peritoneum. Abdominal incision closed with ten silk sutures. Temperature at close of operation 98⅘° F. Pulse 90—lower than at the beginning. Some abdominal distension on the second day which was promptly and permanently relieved by free evacuations of the bowels with salines. The temperature soon resumed its customary oscillations, but there was no bad symptoms attributable to the abdominal section, and the patient made a satisfactory recovery.

The writer mentions as the most important points in the technique of Cæsarean section, asepsis, the secure closure of the uterine wound by the typical Sanger suture, with silk, the avoidance of all scrubbing and the use of antiseptics of any kind in the aseptic uterine cavity, and the avoidance of irrigation or much sponging of the peritoneum. The resort to saline cathartics soon after the first expulsion of flatus, the writer considers a valuable measure. The best time for operating in his opinion is an appointed time immediately before labor. The simplicity of the technique, and the comparatively favorable condition of the patient in timely operations he thinks entitles us to expect in Cæsarean delivery quite equal to or better than the best records of laparotomy in disease.

A CASE OF LATENT NEPHRITIS WITH SUPPRESSION OF THE URINE IN CHILDREN.

By G. D. THOMAS, M. D.,
CHICORA, PA.

In The Medical and Surgical Reporter for Nov. 21, 1891, appears an article from the pen of Dr. Alexis M. Léon on "Latent Nephritis with Suppression of Urine in Children." The infrequency of the occurrence of this disease is noted in this article, and on account of its rarity I take this opportunity of adding another to the rported cases:

Eddie E——, aged eight years (taken sick on his eighth birthday). Family history—Father and mother both alive and healthy. Two brothers, two sisters, all healthy. Previous history—Had had no serious illness up to the present attack, had passed through measles and chickenpox (?) without complications; two years before had scarlet fever, which was considered a light attack, speedy recovery without known sequelæ. For a year he had expectorated a great deal. On being corrected for the habit, said "he could not help it, as it came in his mouth." Being a neighbor's child I had noticed his waxy appearance for a few months before his attack. The parents can remember now that he was less active lately than in former years, and that he could not stand as much cold as usual. Was constantly in cool weather seeking the fire. Had never observed any œdema or dropsy before attack. Has had no cold, nor has he been particularly exposed more than other school children.

Present history—Saw the patient for the first time Tuesday, Dec. 8, at 9 a.m. Had vomited some through the night and complained of head-ache. Temp. 99°. Pulse 56 and compressible. Slight œdema of eyelids and face; none at ankles or elsewhere. Tongue brownish-white coat. Prescribed a calomel purge and made request for morning urine to complete diagnosis.

Patient seemingly much better after evacuations, playing and singing with the other children during the evening.

Wednesday, 8 a.m. Patient not so well this morning. Has vomited several times through the night. Head-ache continues. Still walking around but is apathetic, and

inclines to be on lounge. Temp. 99°, pulse 58. Bowels have moved five times. Œdema of face increased; some anasarca on dorsum of feet. The urine voided in the morning was obtained and amounted to about one ounce. On examination by heat it coagulated in a mass. Microscopically, a few casts (hyaline). Amount was so small that specific gravity was not taken. Ordered the patient to bed and began active treatment, the object of which was to sustain him and have the skin and bowels perform the function of the kidneys. Prescribed infusion of digitalis with acetate of potassium, and sulphate of magnesia. Diaphoresis promptly obtained. Œdema of face rapidly increased, nearly closing eyes by 6 p.m. Some convulsive twitchings. Temp., now (6 p.m.) 103°, pulse 74. Suppression of urine complete. Pilocarpine and salicylate of sodium added to the treatment. Bowels acting every two or three hours. Drinks freely of water, milk, and lemonade.

Thursday, 8 a.m. Patient passed a good night. Strength still good. Temp. 98.5°, pulse 74. Œdema much less in face. Œdema in other parts increased, especially in scrotum.

Thursday, 6 p.m. Symptoms little changed. One of consulting physicians catheterized patient, obtaining seven or eight drops of urine. Suppression still complete. Hot, wet pack ordered to aid in diaphoresis. Comes out with good pulse, and strength maintained.

Friday, 8 a.m. No change. Anuria complete. No convulsions. Two more hot, wet packs, the patient resisting, they were discontinued; gave good results however.

Saturday, Dec. 12. Symptoms nearly the same. Temperature slightly sub-normal, 97.9°. Small doses of pilocarpine ordered.

Sunday, 8 a.m. Suppression still complete. Bowels and skin still active. Pulse 58, temp. 98.2°. Losing strength. Has slept several hours through the night. Continues to take nourishment. More œdema on eyelids.

Sunday, 6 p.m. Since 4 p.m. patient has been rapidly failing. Respiration 44, pulse variable, 90 to 110, weak and thready. Temperature 99°. Gradually sinks, the end coming at 11 p.m., by asthenia.

Remarks: The points of interest in this case are: (*a*) the long and continued suppression; (*b*) the absence of convulsions; (*c*) the idopathic (?) nature of attack.

During the time of treatment from Tuesday morning until the following Sunday night, suppression was so nearly complete that the amount was counted by drops, and the sum total would not have exceeded a drachm and a half. The absence of convulsions is to be considered when so long a time elapsed with anuria complete. During the first twenty-four hours there were some convulsive twitchings of muscles of the face with grating of teeth. This was also the case during the last twenty-four hours of his life. Death was dreaded and expected from the start, and the family forewarned as early as our Wednesday morning visit. The latent nature of the disease is worthy of note. In studying the previous history of the case, the attack of scarlet fever seems to be the only exciting cause obtainable. And from the family as well as the then family physician, comes the statement that the attack seemed very light, and a good recovery promptly obtained. The attack apparently came unprovoked, but was none the less exaggerated in its manifestations.

SOCIETY REPORTS.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON PÆDIATRICS.

Stated Meeting, Feb. 11, 1892.

The greater part of the evening was devoted to a discussion on the therapeutics of Diphtheria. It was opened by Dr. Joseph E. Winters, who confined his remarks to a consideration of "The Best Disinfectant and Best Apparatus for Use in the Mouth and Nose," and exhibited the apparatus which he employed.

He assumed that all were agreed that the disease is primarily local, and due to the Klebs-Loeffler bacillus. At no time in the course of the disease do these bacilli invade the blood; they are confined to the superficial parts in the immediate neighborhood of the membranous exudation. The tonsils, naso-pharynx and nasal passages are in most cases the initial points, and when it is remembered that these bacilli, when brought in contact with a healthy mucous membrane, will not provoke diphtheria, the importance of avoiding the application of all irritating substances to the nose and throat becomes at once apparent. Such treatment by irritating applications is positively dangerous, as the adjacent tissues are likely to become fresh points of infection. If a very small quantity of boric acid or of carbolic acid be added to a culture medium, the growth of the Loeffler bacillus will be materially hindered. This shows that it is needless to use irritating

substances with the idea that they are necessary in order to successfully cope with the disease. The local treatment should be such as will admit of the patient maintaining the recumbent posture at all times, and the speaker favored the use, for a child, of a small crib, with one side capable of being let down to allow the attendant proper access to the patient. The pillow and bedding should be protected by rubber sheeting, so arranged as to carry off the irrigating fluid into a proper receptacle. He advised the use of a Davidson syringe with a nasal tip, and a saturated solution of boric acid, or a ten per cent. solution of peroxide of hydrogen, from half to one pint of the fluid being required at a time. If the irrigation be performed through the mouth, much of the debris is liable to be swallowed, while if it be done through the nose, there is not only less resistance, but the fluid flows out either through the other nostril or through the mouth. Occasionally, in severe cases, it becomes necessary to irrigate through the mouth, and under these circumstances he favored attaching a rubber tube or soft catheter to the tip of the syringe, and passing it along the side of the mouth to the last molar tooth. In cases of ordinary severity, these irrigations, whether through the nose or through the mouth, should be repeated about every two hours; where there is much obstruction, or fetor, it should be done even more frequently. The first syringing should always be performed by the physician himself, no matter how experienced the nurse may be. After the first time, there will usually be but very little resistance on the part of the patient, and almost no exhaustion, in which respect this method compares most favorably with all the other methods of local treatment commonly employed.

External applications form an essential part of the local treatment of diphtheria, and among these steam was one of the most generally useful. The Arnold Steam Sterilizer with the croup kettle attachment was a good croup kettle, which was more than could be said for most of the others in the market. All croup kettles should be furnished with two or three feet of large rubber hose, which may be slipped over the spout of the kettle. In order to be efficient, the steam must be brought quite near to the little patients while they are asleep, and in order to do this, and follow the frequent changes of position of the child in the crib, it is absolutely necessary that a flexible tube be attached to the kettle. He usually placed in the water in the steam kettle two drachms of oil of eucalyptus and two ounces of turpentine. He preferred, as a source of heat, a gas stove to a spirit lamp.

There was another external application which he had found very useful, and the use of which he had advocated before this section some six or seven years ago. It was the inhalation of the fumes from burning sulphur, or sulphurous acid gas. He had found nothing which had given so much relief to the inflammatory swelling and to the dryness of the throat, and the pain on swallowing; it was far more efficient for this purpose than either steam or cocaine. It was quite remarkable that when the atmosphere of the sick room became so laden with the sulphurous acid as to make it absolutely unbearable to the attendants, the patient experienced the most relief from it. He had noted this in his own case, when sick with diphtheria, yet since his recovery he finds that his throat is as sensitive to this gas as are the throats of the attendants. He had observed this in many instances, and Dr. Van Wagnan, of Newark, had noted the same effect upon himself. His custom was to burn a sulphur candle in an adjoining room, or even in the sick chamber itself. The sulphurous acid gas promotes secretion, and seems to favor the exfoliation of the diphtheritic membrane.

Dr. J. Lewis Smith remarked that Dr. Winters used the peroxide of hydrogen in greater dilution than was the custom with a great many physicians, and did not seem to make any distinction between the solution for the nares and that for the mouth. For the fauces, Marchand's peroxide of hydrogen solution, one part to two of water, he thought about the strength, and for the nares, one part to five or six of water.

Dr. L. Emmett Holt said that he had tried a ten per cent. solution, the strength recommended by Dr. Winters, on his own nose, and had been astonished at the amount of irritation which even this dilute solution produced.

Dr. H. D. Chapin followed with a paper on "Quarantine and Disinfection in Limited Apartments; the Precautions for the other Members of the Family." He said that in most cases the end room or parlor should be selected, and all superfluous articles removed. It was a common custom in the tenement houses for the patient to be placed on a sofa, but this should be carefully avoided, a cot being selected instead of either bed or sofa. The attendant should have a wrapper to wear in the sick room only, and the secretions should be collected on rags and then burned.

The Board of Health furnished a disinfectant solution consisting of chloride of zinc, four ounces, and chloride of sodium, two ounces to the gallon of water; this was useful for soaking the linen in before boiling it in the laundry. After the termination of the case, quilts, pillows and comforters should be thoroughly shaken on the roof, and exposed for many hours to fresh air and sunlight; the floor, walls and ceiling should be washed with a 1:20 solution of carbolic acid, or a 1:1000 solution of corrosive sublimate, and the same fluids might be used to flush out the sinks and water-closets. If the walls were papered, they should be rubbed with stale bread-crumb. He still believed that sulphur fumigation was useful; possibly the thorough airing which must necessarily follow may not be an unimportant factor. If the municipal authorities could be induced to establish stations or places of refuge for the well children in families stricken with the disease, great good would certainly result.

Dr. Allen said that in regard to the precautions to be taken by the physician himself to prevent the spread of the disease, he wished to direct attention to a very useful contrivance which he had seen in use in Europe, but which did not seem to be known here. It was simply the interposition of a glass plate between the physician's face and the patient while local applications or examinations were being made. He had more than once seen this screen intercept particles of diphtheritic membrane and secretions, which otherwise would have lodged on the physician's face or beard, and might have been the means of carrying the disease to his own family.

Dr. A. Seibert said that he covered himself with two aprons, and thoroughly washed his hands and arms, and if necessary his face with Labarraque's solution, before leaving the sick room. He believed that many cases of diphtheria were contracted by children crawling around on an infected carpet, and carrying the contagion on their fingers to their mouths.

Dr. Fischer referred to an investigation now in progress, which seemed to show that the sewer pipes had much to do with spreading diphtheria to different parts of the house.

Dr. L. Emmett Holt took up the subject of feeding, and demonstrated a method of forced feeding. He thought the most common mistake was to overdo the matter of feeding and stimulation, so that when a crisis did arise, but little could be done. Ice cream and wine jellies were often swallowed, but the former very often disagreed with the stomach, and the latter were often open to the same objection, and moreover contained but little nutriment. Milk should be selected, and might be given either hot or cold, according to individual preference, properly diluted to suit the age of the child. Mutton broth, beef juice, wine whey, oatmeal and barley gruels, and junket, cold and flavored with a little wine, were all valuable additions to the dietary. Kumyss, if taken well, is very valuable, but unfortunately few children cared to drink it in diphtheria.

Stimulants should usually not be mixed with the food, as it often causes a disgust for the food, nor is it desirable to give it till the heart shows some sign of weakness. A child can rarely digest a meal in less than two hours, hence nothing but predigested foods should be given oftener than this. The quantity of food should be somewhat less than the same child would ordinarily digest well in health. When stimulants are indicated, they may be pushed until the desired effect is reached, the only limit being the tolerance of the stomach. They are best given in small and frequently repeated doses, hence, it is better to prescribe the quantity to be given in the twenty-four hours, and allow the nurse to use her judgment as to how she can best give this quantity in the required time.

In many cases where there is much sepsis, or great prostration, all nourishment and stimulants will be refused, and neither coaxing nor commands will avail. The rectum in young children is usually so irritable that it cannot be depended upon for more than two or three nutrient enemata at the most, hence one is forced to feed by the mouth or nose, the former was usually preferable unless there was a great deal of resistance. Completely peptonized milk or kumyss should be given in this way, along with the prescribed quantity of stimulants, every four hours, and this will be sufficient to maintain proper nutrition. The apparatus consists of a glass funnel, a piece of rubber tubing, and a soft rubber catheter. The red catheters made by Whitall, Tatum & Co., he preferred to Tiemann's soft catheters, simply because they were a little stiffer.

Dr. Abraham Jacobi spoke of "the Constitutional Treatment." He renewed his advocacy of corrosive sublimate, and stated that babies would take from one-fourth to one-half of a grain of this drug in twenty-four hours, if given in small doses, *largely diluted*, without having stomatitis or enteritis. If diarrhœa should occur, a few doses of paregoric will speedily control it. The failures

with this treatment usually occurred from not using the bichloride sufficiently diluted; one part in eight or ten thousand of water is the proper dilution. He also spoke of the value of calomel inhalations in pseudo-membranous croup when repeated every three hours, keeping the patient in a closed tent for about five minutes, and allowing about ten minutes for the evaporation of ten grains of calomel.

The pulse should be carefully watched in diphtheria, remembering that a rise of ten beats may mean that heart failure is imminent. It is important to remember that the ordinary doses laid down in the books will not answer in the face of sepsis from diphtheria. For instance, quite recently a baby was given one minim of Squibb's fluid extract of digitalis every hour until thirty-three doses had been given, before the drug began to show its effect on the heart; then the digitalis was given only once every three or four hours. When heart failure threatens, stomach absorption is often very imperfect, and subcutaneous administration of stimulants must be resorted to. Then, one part of camphor dissolved in four or five parts of sweet almond oil serves a good purpose as a cardiac stimulant which can be readily and painlessly injected under the skin. The salicylate or soda-benzoate of caffein dissolves in two parts of water, and is therefore eligible for subcutaneous administration.

Dr. A. Seibert then exhibited the syringe which he employs for making what he terms "sub-membranous injections" in diphtheria, a method which he had been using with apparent success for the last eighteen months. He injected a much larger preparation of chlorine water than the officinal one, and of course, made use of the usual method of constitutional treatment in conjunction with this new method of local treatment.

THE DROP BY DROP METHOD OF ADMINISTERING CHLOROFORM.

Two communications appear by Brandt (*Centralblatt f. Chirurgie*, No. 47, 1891) in which especial stress is laid upon this method of administering chloroform. Zuckerhandl claims that the method has been extensively employed in Dillel's clinic at the Vienna General Hospital with excellent results. Brandt states that Lauenstein, in the Sailors' Hospital at Hamburg, has used the same method for six years without a single accident occurring in consequence of the use of this anæsthetic agent. Only in rare cases is morphia used with chloroform anæsthesia.

SELECTED FORMULÆ.

FOR SORE THROAT.

℞ Cocainæ hydrochlorat.....gr. viij.
Acid. carbolici.....3 j.
Glycerini.....f 3 iv.
Aquæ rosæ.....ad f 3 xij.
M. Sig. To be diluted with an equal quantity of water, and used alternately as a spray and gargle.

CATARRH, NASAL.

℞ Sodii chloridi.....3 i.
Glycerinæ.....3 iv.
Aq. rosæ.....oz. i.
Aq. dest.....q. s. O. i
Acidi carbolici.....gtts. v.
M. Sig. Snuff up nose several times daily.

or,

℞ Tannin glycerol.....3 i
Glycerinæ.....3 iii.
Acidi carbolici.....gtts. iii.
Aquæ rosæ.....3 ii.
Aquæ dest.....3 ii.
M Sig. Use with atomizer.

or,

℞ Potass. bichromat.....gr. i to x.
Aquæ rosæ.....3 iv.
M. Sig. Local spray.

CASCARA SAGRADA AS A PURGATIVE IN CHILDREN.

This drug has been found to be the most reliable purgative in infants and children. It may be prescribed as follows (*Lo Sperimentale*, No. 23, 1891):

℞ Tr. cascara sagrada, } ää grammes 10.
Simple syrup, }
From one-half to a coffee-spoonful, according to the age of the children.

WHOOPING COUGH.

Dr. Galvagno (*Lo Sperimentale*, No. 23, 1891) proposes the following formulæ:

℞ Distilled water.....grammes 100.
Resorcin, }
Antipyrin, } ää gramme 1.
Muriatic acid.....gtts. 10.
Simple syrup.....grammes 30.

℞ Gum arabic solution.....grammes 100.
Resorcin, }
Antipyrin, } ää gramme 1.
Syrup of pine tar.....grammes 30.
Three to five tablespoonfuls a day.

PALATABLE QUININE SOLUTION.
(LUTZ.)

Quinine sulphate.....gramme 0.05.
Sulphuric acid. dilute..... " 0.05.
Sol. saccharin, saturated..... " 1.00.
Water.....grammes 9.00.
Spirit of peppermint.....gtt. 5.

CHRONIC DIARRHŒA WITH INTESTINAL FERMENTATION.

Dr. Eichler (*La Cronaca Medica*, September, 1891) uses the following:

℞ Salol.....grammes 3.
Ol. ricini..... " 15.
Symp. rhei..... " 30.
Aq. cinnamon..... " 120.
Gum arabic, q. s.
A large spoonful eve hour l t laxative acts.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO. (Incorporated)
PROPRIETOR AND PUBLISHER.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.)

CHARLES K. MOUNT, Advertising Manager.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates),..... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts,.....$1.50 each.
Bovine Points or Quills,..... 1.00 a doz.
Humanized Crusts,..... 1.00 small.
Humanized Crusts,..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

LEADING ARTICLE.

RECENT INVESTIGATIONS REGARDING THE ÆTIOLOGY AND TOXICOLOGY OF ASIATIC CHOLERA.

With the discovery of the comma bacillus in Asiatic cholera by Koch in 1884, the investigations relative to the ætiology of this disease assumed a new phase. All methodically schooled investigators were forced to the conclusion that the comma bacillus only was found in cases of Asiatic cholera, and were, therefore, necessarily led to the acknowledgment that this bacillus was the exciting cause of the disease. Only a few investigators claimed that their appearance was due to a preëxisting infection of the disease, and that they were secondary to, and not the cause of the malady.

This endeavor, by means of an illogical train of thoughts, to modify the brilliant discovery of Koch, was shattered by the logic of potent facts. Klein and Lewis who went to India with the idea of overthrowing this theory, found that even there the conservative English physicians had to a large measure embraced the parasite theory as one long in accordance with their views resulting from actual experience, and so the researches of these two did little but strengthen Koch's theory.

The most recent investigations in this domain have been those of Dr. D. D. Cunningham, of India, who, armed with scientific methods and apparently good arguments, has endeavored to destroy the groundwork of our present conception of the ætiology of Asiatic cholera. Even Cunningham cannot and does not deny that he has found Koch's comma bacillus only in cases of Asiatic cholera, and considers them, therefore, of great diagnostic value. He, however, questions their ætiological importance, and returns to the already rather hackneyed theory that these bacilli are developed under the influence of some unknown choleraic cause. His main arguments against the ætiological importance of the comma bacillus are as follows:

1. That in the positive cases of cholera, in

which he found the comma bacillus, he also found nine other germs, not exactly similar to Koch's bacillus, which he designates as various "species" of the comma bacillus.

2. That he occasionally in one and the same case found as many as three of these so-called species.

3. That in a few typical cases of Asiatic cholera he found no comma bacilli.

These different "species" he has succeeded in obtaining cultures of.

In the determination of Koch's species, Dr. Cunningham has only been guided by Dr. Koch's descriptions of the bacillus. All those bacilli which did not appear precisely as Koch had described them were dubbed as different species. Koch, however, never asserted that the forms of the comma bacillus described by him were the only ones found in Asiatic cholera, but described those forms occurring most frequently as the typical forms, leaving the possibility for a slight variance in shape of form always open.

To base so important a theory on a slight variance in the shape or form of a bacillus, is, to say the least, a procedure based on grounds that cannot be regarded as strictly scientific. Such slight variations are common in a large number of microörganisms—we need only remind our readers of the varied forms of the micrococcus prodigiosus. This Cunningham seems to have entirely overlooked in his work, classing all such bacilli as varied in any detail from Koch's description of the typical comma bacillus as another bacillus or "species."

If, therefore, in Asiatic cholera a bacillus is found which does not exactly coincide with Koch's description of the comma bacillus, it must be proven beyond all doubt that the bacillus is really another "species" or only a modification of the comma bacillus. Denecke, Finkler-Prior, and Gamaleïa have all found modifications of the comma bacillus, and recognized them as such. Buchner, Gruber, Zaeslein, and Ferdinand Hueppe have all discovered during the past few years modifications of the comma bacillus, which have been proven to be "nutritive modifications" of the same bacillus, that is to say, that the modifications depended upon the nutritive element upon which they were cultured. Most interesting in this connection is the recent work of Dr. Ferdinand Hueppe and his assistants Drs. Wood and Scholl, a report of which appears in the *Deutsche Medicinische Wochenschrift* of a recent date, and to which this article is indebted for many data and quotations.

Hueppe has succeeded in obtaining all the modifications or "species" described by Cunningham, from a single form of the comma bacillus, obtaining microscopically both the round and oval forms, the comma in the most varied shape, and, finally, also the partially screw-shaped form mentioned by Cunningham. Microscopically he has obtained cultures which would not dissolve gelatine, and so on, past the typical colonies described by Koch to those which would entirely and rapidly dissolve the gelatine medium.

Hueppe, therefore, affirms that the "species" described by Cunningham are nothing more nor less than nutritive modifications of Koch's comma bacillus, and that the evidence brought forward by him is insufficient even for the assumption of any other bacillus being the ætiological factor of the disease.

While we have thus demonstrated the possible fallacy of Cunningham's assertions, based as they undoubtedly are upon firm conviction, it will be well for us to add a few salient points in confirmation and proof of Koch's claims, basing our assertions on the results of the most recent bacteriological investigations in this domain in Europe.

Never has the comma bacillus of Koch been found in the intestines of healthy individuals—or still more exactly, never has it been found in the intestines of other than those suffering from cholera—although Klein has vaguely endeavored to show that they may exist in the healthy organism. Whether or not during the progress of an epidemic, a subject physically indisposed to infection may take into his system the germs of cholera without suffering from the disease is by no means proven. Of the varieties of

comma bacillus that can be grown in cultures, only one—the Finkley-Prior variety—has ever been found in the mouth and intestines of a healthy individual.

In Europe, Koch's comma bacillus has only been found in unquestionable cases of Asiatic cholera. And in this conclusion all investigators agree, which is in unison with our epidemiological experiences regarding the introduction of the disease from India, and decidedly in confirmation of Koch's theories. For all these reasons we may be safe in concluding that from all points of view the only tenable ætiology of Asiatic cholera is that which may be termed the "parasitic," and that Koch's views of the ætiological importance of the comma bacillus is proven.

Koch's statements regarding the purely contagious character of cholera, are subject to discussion. On account of the ease of the inoculation of animals from pure cultures of the bacillus, many investigators were prone to accept the possibility of a similar direct inoculation in man, and not to lay sufficient stress upon the possibility for disposition or immunity, and the importance of miasmatic conditions as affecting the parasite when not in the human organism. In cholera this may have been initially excusable in so far as the hardiness exhibited by the cholera bacillus against both dryness and decomposition was well known. Nevertheless, the fact of the ease with which the bacillus could be cultivated, opposed to the one-sided contagion theory, should have aroused the theory of infection.

We know of no unnecessary proofs in nature, and the saprophytism of the comma bacillus as such, and ease with which the parasitic comma bacillus can accustom itself to a saprophytic life after living in the animal organism although the nutritive element upon which it feeds may be most poor, is alone sufficient to award the saprophytism of the comma bacillus in connection with the miasmatic view of the disease an important rôle in the epidemiological ætiology of cholera.

We cannot, therefore, in a just consideration of this important subject confine ourselves on the one hand to a "purely contagious" view of the disease, or on the other hand to a "purely miasmatic" view.

Hueppe's experiments have conclusively shown that in the saprophytic life of the comma bacillus and the parasitic life, there are the following differences: During the anaërobic life of the parasite in the intestines, in consequence of anaërobic decomposition of the nutritive matter there, the comma bacillus is unusually poisonous, and capable of showing but slight resistance to external influences; while in their aërobic life they show marked variances and a lessening of their virulence, but on the contrary gain greatly in hardiness.

From the results of the above observations Hueppe sums up the subject succinctly in the following clause: "The comma bacillus is the cause of Asiatic Cholera; these bacteria give rise in the intestines to a poisoning of the organism, which action is not dependent upon their anaërobic life there. In consequence of this anaërobic life in the intestines these parasites become highly poisonous, but, owing to the poor development of membrane, are very prone to influences from external sources. In this virulent but feeble condition they leave the body, so that they (by reason of this weakness and not from lack of virulence) are not suitable for direct transmission from the diseased person to the healthy organism, and, therefore, direct contagion from cholera is exceptional. In their aërobic growth outside of the organism they become more hardy, that is to say, more suitable for infection, and this infection is determined by outside causes, and as a rule is indirect or miasmatic.

The cholera parasite, according to Koch's demonstration, lives only in the intestines, and does not enter either into the blood or tissues. Koch, therefore, sought to explain the infectious actions of these parasites in claiming that the choleraic process was one of poisoning caused by the parasite forming a poison in the intestines which was absorbed into both blood and tissues. In fact several investigators, including Nicati, Rietsch, Koch, Van Ermengen, Klebs, and Hueppe discovered a poisonous action in the bacillus,

and Brieger was able to obtain from a basic culture ptomaines which he isolated as toxines. But yet these experiments, which seemed to promise so much at the outset, proved to be failures, and the entire second part of the ætiology of cholera, and the entire toxicology of the comma bacillus remained an unsolved problem. The fact had been entirely overlooked that the class of poisons thus demonstrated occurred only at a late period of the aërobic life of the parasite, and Hueppe had been able to prove in his laboratory that the development of these toxines destroys the true choleraic poison.

It, therefore, remained necessary to primarily answer several fundamental questions; and this Hueppe, with the aid of his assistants Wood and Scholl, has been able to do. First, since the bacteria in the intestines live without air, or at least with only a minimum quantity of air, therefore, the problem of the anaërobiosis of the parasite must first be solved; and, secondly, the nutritive surroundings must be rendered more natural than those obtained by *bouillon*, or in other words, made as closely as possible to simulate the nutritive soil existing in the intestines.

Hueppe found that by restricting the amount of oxygen that came in contact with cultures he could gradually force the parasites to a strict anaërobic mode of life. Hueppe also found that to ensure the growth of the parasite in such a condition of strict anærobiosis, a but slightly changed and if possible genuine albuminoid body was necessary. He, therefore, conducted his cultures in raw eggs, and was in this way enabled to obtain so much poison in an egg that he was able to kill three guinea pigs under symptoms far more characteristic than any heretofore obtainable through other inoculations. Hueppe therefore, considers himself justified in assuming that he has thus solved the problem of the second question relating to the ætiology of cholera.

Lack of space forbids our going into any detailed description of these vastly interesting experiments of Hueppe and his assistants, and we must restrict ourselves to a brief recital of the principal results obtained, which are as follows:

1. The comma bacillus can be cultured both in regard to the quantity of air (anaërobiosis) and the nutritive soil (albumen) under precisely the same conditions as those found in the intestines of the human organism.

2. In such cases the comma bacillus forms from the albumen a characteristic poison which belongs to the albuminoids. From the albumen is formed a substance which in a purified state gives all the reactions of a peptone. This poisonous peptone paralyzes animals into which it is injected, their coat becomes deranged, the conjunctival reflex is entirely absent, then twitching of the extremities, and finally death occurs, in the majority of cases in a few minutes.

This substance like other peptones is not altered by boiling, in so far as its chemical reactions are concerned, but its poisonous action is destroyed if it subjected to a temperature of 70–75° C. for any length of time or immediately if it be boiled.

The peptone answers all the indications of a specific and typical cholera poison.

Hueppe's experiments show that while the ptomaines found by other observers were important and interesting as far as the saprophytic life of the bacillus is concerned, yet they bore no relation to the parasitic life of the germ.

It is a well-known fact that epithelial cells in the intestines act as guards against the absorption of such diffusible poisons as these abnormal peptones and albuminoids, and that every disintegration of these epithelial cells leaves an opening through which the poison may reach the general organism. If this be true in the case of ordinary diarrhœas and other intestinal complaints, how much more so is it likely to be in the case of so acute a process as cholera, especially if the normal functional condition of these cells is entirely suspended.

It is further known that these epithelial cells are disintegrated by the growth of the cholera bacillus within the intestine, and therefore the probability of an absorption of the poison greatly enhanced.

As the poisonous action of cholera is a most acute process, the therapy which acts as an antidote is at best greatly hampered, and it is for this reason that our treatment has been so unsatisfactory. A therapy that would check the growth of the poison makers (the bacilli) is indicated, and it is on this ground that the use of the salols has been attended with such favorable results. But the question of therapy we must, however, leave for a future article.

BOOK REVIEWS.

PHYSICAL DIAGNOSIS: A GUIDE TO METHODS OF CLINICAL INVESTIGATION. By G. A. Gibson, M. D., D. Sc., T. R. C. P., Ed. Lecturer on the Principles and Practice of Medicine in the Edinburgh Medical School; Examiner on Medicine and Clinical Medicine in the University of Glasgow: and William Russel, M. D, T. R. C. P. Ed. Pathologist to the Royal Infirmary of Edinburgh; Lecturer on Pathology and Morbid Anatomy, in the Edinburgh Medical School. With 101 illustrations. New York: D. Appleton & Co., 1891.

The authors of this new addition to our list of text-books of physical diagnosis are to be congratulated upon having produced one of the best practical guides to the knowledge of that most important subject. The arrangement and general plan of the subject as treated by them is more nearly perfect than that usually adopted in such treatises, and will undoubtedly be highly welcome to American students by reason of its simplicity and thoroughness of detail.

Temperature is first taken up, the various types being well illustrated by charts, and is followed by a chapter devoted to the integumentary system, which is excellent and not too full. Next, the circulatory system is considered, and in this section some original cuts will emphasize the points intended to be impressed upon the student. The same may be said of the next chapter which systematically goes over the latest views regarding the physical exploration of the respiratory organs. The alimentary system and the abdominal viscera are next dealt with, followed by a chapter devoted to the urinary system. The book ends by a chapter upon the physical diagnosis of nervous diseases, and an excellent chapter upon examination of the eye, ear, larynx and naso-pharynx.

The value of the work lies chiefly in the manner in which the subject is presented, in the generalization of symptoms instead of their particular significance in any one condition of disease, and in the faithful attempt of the authors to accurately picture to the student the conditions giving rise to physical signs, instead of attempting to deal with diseases individually, regarding their physical symptoms. The metric system of weights and measures is used throughout. The cuts are original and well executed.

Students and practitioners will find this treatise a valuable one, and principally because it limits itself strictly to the province of physical diagnosis, while at the same time its completeness of detail and description leaves little for adverse criticism. To those already acquainted with the careful work of Dr. Gibson, this book will not come as a surprise

BOTANY. A CONCISE MANUAL FOR STUDENTS OF MEDICINE AND SCIENCE. By Alex. Johnstone, F. G. S., Lecturer on Botany, School of Medicine, Edinburgh. With one hundred and sixty-four illustrations, and a series of floral diagrams. New York: D. Appleton & Co. 1891.

In the preparation of this manual the author has endeavored to compile an illustrated digest and general note-book which the student would find useful in conjunction with systematic instruction.

This little book is, of its kind, one of the most admirable we have ever read. It is written with conciseness and marvellous clearness, the illustrations and the floral diagrams are excellent, and the work of the publisher is equally commendable. It is just such a manual as will thoroughly be appreciated by beginners in botany.

LITERARY NOTES.

—William Dean Howells' new novel, "The World of Chance," began in *Harper's Magazine* for March. Judging from the opening chapters alone, this story promises to outrival in interest anything hitherto written by that distinguished author. This number of the *Magazine* is also especially strong in American subjects.

WHEN BUSINESS AND MORALS ARE ONE.

—It is a very common thing for people to lament that they did not get rid of this or that property before its value depreciated. Of course, what they are really sorry for is that they could not have contrived to saddle their loss on some one else. It is a sign of the imperfection of contemporary benevo-

lence that good people should have such feelings and should regard them as matters of course. They are humorously unchristian. The utmost the average contemporary moralist enjoins is that a man shall not "unload upon his friends." He cannot so much as imagine a scruple about sending out cadescent stocks in open market.

It will not be so when the millennium comes. Property will continue then, as now, to fluctuate in value, but the prospect of a depression will no longer strike the owner as a good reason for selling out. His superior moral sense will then, as now, be profitable to his estate, since property doesn't always depreciate as much as is expected, and often in the end it recovers more than it lost. But the great advantage from a business point of view of the perfected altruism will be emancipation of the altruist from panic and all its consequences, since the man who is more ready to accept his loss than to pass it on, is not to be scared into a foolish sacrifice by the shadow of it beforehand.—From "The Point of View," in the March *Scribner*.

WINE DRINKING AT DINNERS.

—It is an undoubted fact that the serving of many and heavy wines at large dinners is gradually becoming a thing of the past, writes George W. Childs in the January *Ladies' Home Journal* Of course, I do not mean that wines are no longer served, for they are and always will be, so long as civilized men consider them a feature of dinners. But I do mean that of the varieties of wine there are fewer, of the quantities less, and of the qualities lighter, than was the custom ten years ago. Were I preparing for a large dinner for men—which is always from the nature of things more heavily wined than an ordinary "mixed" dinner—I should not think it in the least degree necessary to order anything like the same amount or assortment of wines that would have been imperative a few years ago. And in extenuation of the statement that the qualities of the wines served are becoming lighter, the simple fact that at the average English dinner table port wine has been almost entirely superseded by claret, may be cited. It is also becoming a very ordinary thing at English dinners to meet prominent men who do not drink wines of any kind, and in our country this is becoming more and more a fact. Of course, a dinner must have fluids; the best of solids require some liquids with which to relish them, and a dinner would be but wasted energy and material without them. But I think it is no longer imperative to serve wines, or at least we can serve with them some other beverage which will be of equal pleasure to the constantly increasing set of people who find that wining and dining together is rather too heavy a combination for their comfort.

CORRESPONDENCE.

HYPODERMIC INJECTION OF WATER AS A LOCAL ANÆSTHETIC.

Editor Medical and Surgical Reporter:—In your issue of January 9th, 1892, you quote Dr. C. L. Schleich's experiments on the production of local anæsthesia by the hypodermatic injection of water; his article appeared in the *Deutsche Medizin Zeitung*, No. 66, 1891.

This is not a recent idea, as many journals copying the same have seemed to infer; on the contrary it has been known for fifteen or twenty years. The *Boston Journal of Chemistry* for October 1876, says in this regard, "It is found that subcutaneous injections of water often relieve pain just as effectually as when morphia is used. Nerve pains, neuralgia, sciatica, and the like are more likely to be relieved than the sufferings incident to chronic progressive diseases, as cancer." Then again Dr. Lafitte in a letter to *l' Union Médicale*, of October 5th, 1875, says that he uses an injection of two grammes and then waits a few minutes; if the pain is not relieved then he injects a second similar amount, even in some cases injecting as much as "five or six syringefuls.' He thinks that one should not inject less than two grammes nor more than ten. Dr. Dieulafoy recommends that eight or ten drops of water be injected into the seat of the greatest pain; he adds, that if necessary, this may be repeated ten, twelve or fifteen times at one sitting.

Dr. Griffith writes at length to the *British Medical Journal* and I will quote his words—

"I have attended many patients who had been in the habit of taking morphia, and have treated them with the hot water plan, to the great improvement of their health, and the weaning them of the baneful poison. Even in cases of delirium tremens which had been accustomed to the injections, and in the fury of delirium persisted in calling out for them, I have employed the hot water and so lulled them to rest. But here I would pause to admit that sometimes this plan would fail me, and then I would fall back upon injecting a small dose of morphia first, following it up with the use of the hot

water in two, three or four hours. But it is in the cure of sciatica and deep-seated pain, as well as brow-ague and similar distress that I have found the hot water injections most beneficial; indeed, I cannot recall an instance of failure. For the purpose of carrying out this method of cure I had, in 1868, a hypodermic syringe made after my own plan. The needle is some inches in length; the cylinder is silver (I had broken many glass tubes or cylinders when drawing in the hot water), and contains a drachm and a-half of fluid, if such an amount should be required to be thrown in. The piston has not a screw action, but runs up and down like an ordinary syringe in order that the water may be expelled with the amount of force the operator may think best. In some instances, burying the needle up to the very end, I force in the hot water amongst the muscles, and then withdraw the instrument immediately afterwards, placing the tip of my finger on the perforation point, and, by a rolling movement, dispersing the fluid in its bed. The long nozzle of the syringe acts as an acupunture needle, the fluid as an additional counter-irritant, the patient complains of a smarting, burning sensation, soon followed by relief from the pain; and if the operation be done in the patient's own home, and while he is in bed, sleep will often supervene. In this manner, I have frequently stopped sciatica, the agony of acute lumbago, or that resulting from a sudden strain or fall, besides other minor pains."

These we see are practically all the same, Dr. Griffith, only, deviating slightly in specifying *hot* water. We see then that the method of treatment has an undoubted age of sixteen years, and if we date from 1868, when Dr. Griffith had his special syringe constructed, twenty-four years. In all probability, from the time of Dr. Griffith's letter, he had used the method before that date.

If there is any efficacy in the treatment therefore France deserves more credit than Germany, and England more than either, for apparently priority is possessed by Dr. Griffith.

I have not read "to contradict or confute," to quote Bacon, but to try to give honor to whom honor is due—that is if there is any honor to be distributed—and to show that Drs. Dieulafoy and Lafitte, but particularly Dr. Griffith, deserve credit for their investigations previous to those of Dr. Schleich.

Charles Milton Buchanan, M. D.,
Washington, D. C.

PERISCOPE.

THERAPEUTICS.

CHLORINE WATER AND QUININE IN TYPHOID FEVER.

Dr. Burney Yeo recommends as the best antiseptic in typhoid chlorine water with quinine. It is made by putting 30 grains of powdered chlorate of potash into a 12-ounce bottle with 40 minims of strong hydrochloric acid, the bottle is to be corked, the gas allowed to generate, then water is poured in little by little and well shaken with the gas, and finally 24 or 36 grains of quinine and an ounce of syrup of orange peel are to be added; of this mixture an ounce is to be given every two, three, or four hours. In the early stage—first week—one or two full doses of calomel—5 to 10 grains—are recommended, especially if there is constipation.—*Amer. Drug.*

THE TREATMENT OF TACHYCARDIA.

The most distressing affection known as paroxysmal tachycardia, or "rapid heart," has unfortunately not generally proved as amenable to treatment as could be desired; but Dr. Poulet of Plancher-les-Mines has recently found a remedy in a little-known plant indigenous to Alsace, which appears to exert a rapid and beneficial influence over the paroxysms. The plant in question is the Coronilla varia, or *faucille*, which, like some other species of Coronilla, is sometimes used as a household remedy, being considered to have cathartic and diuretic properties. Some recent research by MM. Spillmann and Haushalter on a closely allied species—Coronilla scorpioides—showed that the plant acts as a powerful heart tonic, causing an increase in the arterial tension and in the fulness of the pulse, exciting diuresis and diminishing œdema and dyspnœa—acting, in fact, very similarly to digitalis. Dr. Poulet was induced by these researches to make trial of Coronilla varia in heart cases. He employs a tincture made from the entire plant (1 in 5), also a powder made from the flower. The dose per diem of the tincture is from half a drachm to a drachm, and that of the powder from fifteen to thirty grains. These preparations, though they have a strong characteristic odor, are not nearly so disagreeable to the taste as those of Coronilla scorpioides. Details are given of two very severe cases in which these preparations of the Coronilla varia gave almost immediate relief. M. Poulet recommends this drug also in other

heart cases where digitalis has been used, and where it seems to have been given for too long a period, or, as sometimes occurs, where it has begun to act on the gastro-intestinal canal.—*Lancet.*

HYPODERMIC INJECTIONS OF CARBOLIC ACID IN TETANUS.

Strazzeri and Titone report (*Rif. Med.*, Nov. 10th, 1891) a case of traumatic tetanus in which they effected a cure by Bacelli's method of hypodermic injections of carbolic acid. The patient was a boy aged nine, who had fallen on his right knee, bruising and slightly grazing the skin. Eight days after the injury he developed well-marked symptoms of tetanus. He was treated with injections of a 2 per cent. solution of carbolic acid repeated every six hours, opiates being given internally. The boy's surroundings were very unfavorable, as he was one of a large family living in a miserable hovel, which was shared also at night by a mule. In spite of this an improvement in the symptoms was noted after the first few injections. On the fifteenth day the patient recovered the power of mastication, and after four weeks' treatment he was completely cured.—*Brit. Med. Jour.*

DIURETIN.

Kress, (*Münch. Med. Woch.*, Sept. 22, 1891) in a paper reviewing what has already been written on this drug, and describing in detail his own observations in a large number of cases, comes to the following conclusions: Diuretin is a true diuretic, increasing equally the fluid and solid constitutents of the urine. Its action is due to a direct, unirritating influence upon the renal parenchyma; albumen does not appear in consequence of its action, and if already present in the urine its amount is not changed. The frequent favorable influence of the drug upon the organs of circulation is probably produced indirectly. The best results from its use are obtained in cases of acute and chronic diseases of the heart and kidneys, especially acute nephritis and uncomplicated valvular disease. Good effects may be expected in chronic nephritis, and myocarditis, whereas in simple serous effusions, as in tuberculosis, the drug is of no use.

Diuretin can be continued for a long time in large doses, two drachms a day, without any alarming secondary effects. The continued administration of the drug in cases of the above mentioned diseases, does not decrease its diuretic action.

A similar series of observations is recorded by Pfeffer, who strongly recommends diuretin, especially for cardiac dropsy and chronic renal disease. When compared with digitalis, however, diuretin is found inferior as a cardiac stimulant, while superior in its action on the kidneys. Pfeffer's conclusions in other respects resemble those of Kress.

SALICYLATE OF MERCURY IN GONORRHŒA.

The tendency to routine practice in medicine, has long been the bane of the profession. This should ever be reprobated by its friends. In no department of practice is this inclination so manifest as in the treatment for venereal diseases. Well nigh every physician has a "specific method" of treatment for syphilis and gonorrhea. To this is doubtless due the slow progress compared to the treatment of other diseases.

I do not propose, in this paper, to set aright the profession on this subject, nor to add too much to what is already known, I wish, simply, to present the results of an experience, which, if it only stimulates to further research, will amply repay the writer. Having long been in doubt as to the efficiency of the ordinary plans of treating gonorrhea, and having frequently suffered disappointment and chagrin at the tardy convalescence of my patients, I was led to inquire into the rationale of these plans, and consider what, indeed, was the true course to pursue. In this consideration the following points presented themselves: First: this is not an ordinary inflammation, but a specific disease—a peculiar poison, whose toxic properties are manifested in the pathological condition of the part affected.

Second: not only is the origin of the disease due to this cause, but its duration is also dependent upon the same element, present in the pus secreted from the mucous surface of the urethra. If the pus of gonorrhœa will produce the disease when brought in contact with healthy mucous surfaces, it is certainly capable of renewing itself constantly, and perhaps indefinitely as it comes in contact with the lining of the urethra from which it emanates.

Now, if the origin and duration of the affection be due to a specific virus, what is the indication for treatment? I naturally looked for some means by which I might rob the pus of its septic properties. Salicylate of mercury is the remedy I selected, and after a fair trial, in numerous cases, and in all

stages, I feel safe in urging its claims. My plan of treatment is: ℞ Salicylate of mercury grs. ii; aqua dest. oz. vi. Sig.—Inject 3 or 4 times a day.

I find this applicable in all cases, save, possibly, in some advanced stages of gleet where the poisonous element is not present.

In short, I claim that gonorrhœa is a disease due to a specific virus or toxic agent, the gonococcus, and the only method of cutting short its duration, is to rob the disease of this element which is its chief characteristic.—*W. W. Payne, M. D., in Miss. Med. Monthly.*

RAPID ANÆSTHESIA WITH CHLOROFORM.

Dr. M. Cordero reports further on this subject, giving forty new cases. The mortality of those operated upon was 17.94 per cent., but not one case could be attributed to anæsthesia. The mean time to produce complete narcosis was 8.07 minutes; average duration of operations was 18.6 minutes; the average time elapsing between sleep and normal consciousness was 3.19 minutes; the average quantity of chloroform employed for anæsthesia was 18.6 grammes (3⅔ drachms).—*Gaceta med. de Mexica*, vol. xxvi, 1891, p. 265.

SULPHATE OF MAGNESIA IN EPITHELIOMA.

The treatment of warts by the internal administration of small doses of sulphate of magnesium is said to have been attended with a considerable amount of success, even large growths disappearing under the remedy when persisted in for a sufficient length of time. It is now claimed, according to the *Medical Press and Circular*, that epitheliomatous warts may be dispersed by the same means, a paper on this subject having been read before the New Hampshire Medical Society, by Graves. Three drachms of the salt are added to 1 pint of water, and a teaspoonful of the mixture taken four times a day. The author gave an account of eight cases in which the treatment had been adopted with success; but he admitted that the possibility of erroneous diagnosis had to be considered. It was, however, a fact that growths of an elevated character with round or oval bases and ulcerated summits, discharging an ichorous fluid, were transformed by the treatment into perfectly healthy spots, which exhibited no signs of diseased structure, and his conclusion was that the result was obtained by the remedy employed.

STRYCHNINE NITRATE IN TOXIC AMBLYOPIA.

Dr. E. Melville Black makes a strong argument for the use of the nitrate of strychnine in tobacco and alcoholic amblyopia (*New York Medical Journal*, vol. liv. p. 287). The nitrate is chosen for hypodermic use because it is less irritating than the other salts. The site chosen is over the biceps muscle, and cleanliness and perfect solution of the drug (eight grains to the ounce in distilled water) are essential; the required dose may go to twenty or twenty-five minims. In dosage of over ten minims he keeps the patient under observation for a half hour after the injection. He instances four cases in which the patient's present condition, ophthalmoscopic examination and details of treatment were carefully recorded.

SUBCONJUNCTIVAL INJECTIONS OF CORROSIVE SUBLIMATE IN EYE DISEASES.

Darier, (*Arch. d'Ophtalmologie*, September and October, 1891) reports a series of cases from Abadie's clinic in which the treatment indicated in the title of his paper was adopted. This method of treatment seems to have grown out of the intraocular mercurial injections suggested by Abadie two years previously for cases of sympathetic ophthalmitis, and practised by Reymond and others. The syringe employed is Pravaz's, with the needle modified, so that it penetrates the conjunctiva easily and without tearing. The eye is first cocainized. Care is taken that the syringe is perfectly aseptic, the instrument being kept, when not in use, in 5 per cent. carbolized glycerine. Darier has found a 1 in 1,000 solution of the perchloride in boiled water preferable to stronger solutions, and injects from $\frac{1}{20}$ to $\frac{1}{10}$ of a cubic centimetre; the latter quantity contains 1 milligramme of the sublimate. The injection is followed by some œdema of the conjunctiva, and more or less pain of a burning character. The first two injections are given at two days' interval, the third and fourth three or four days later. The continuance of the injections will depend upon the effect produced, and the individual tolerance to the treatment. In cases evidently of a syphilitic nature, mercury should also be administered in other ways. The records published by Darier include cases of iritis and iridocyclitis, keratitis of several varieties, choroiditis, retinitis, and inflammation and atrophy of optic nerves. The results he considers decidedly encouraging in all except the optic nerve cases.—*Brit. Med. Jour.*

MEDICINE.

PRODUCTION OF GLYCOSURIA AND AZOTURIA AFTER TOTAL EXTIRPATION OF THE PANCREAS.

One of the most remarkable observations made on the pancreas in recent times is that of V. Mering, who found that total extirpation of the organ was followed by glycosuria. Hédon (*Comptes Rendus*, cxii, No. 18) has repeated these observations and confirms the statement that the total extirpation of the pancreas is followed by glycosuria and azoturia. But he also finds that the glycosuria may be intermittent, and may disappear for a time. In these cases the increased decomposition of proteids, as manifested by the increased azoturia, is the most pronounced phenomenon, and the same is the case when sclerosis of the pancreas is produced by injecting paraffin wax into the pancreatic duct. In some cases diabetes insipidus, or at least polyuria, may alternate with glycosuria.—*Brit. Med. Jour.*

URTICARIA OF THE THROAT FROM EATING MUSSELS.

At a meeting of the Société Médicale des Hôpitaux on July 3d, M. Laveran (*Sem. Méd.*, July 8th. 1891) showed a man, aged 30, who almost every morning suffered from urticarial eruptions, sometimes on the feet, sometimes on the hands, at other times on the shoulders, and more rarely on the face. On the morning of July 3d the throat had been the seat of the eruption, which produced considerable swelling of the uvula, the pillars of the fauces, and the tonsils. The eruption was accompanied by dysphagia and dyspnœa. When shown the same evening the uvula was still somewhat swollen; there was also a small patch of urticaria on the tongue and a larger one on the hip. M. Moutard-Martin said he had been called one evening to a lady who had been suddenly seized with dysphagia and a feeling of suffocation. Her tongue was swollen and projected beyond the arch of the teeth. He diagnosed urticaria of the mucous membrane of the mouth, and this diagnosis was confirmed by the occurrence during the night of a similar eruption on the lips and on the cheek. M. Rendu said he had some days previouly seen a child which, having first had an attack of urticaria on the forehead, face, and neck, was then seized with swelling of the throat, causing alarming dyspnœa. Diagnosis would have been very difficult had it not been for the eruption on the skin. M. Sevestre said he had once been called to a lady who, half an hour after luncheon, had been seized with distressing dyspnœa. The throat was extremely red and puffy. He was puzzled as to the nature of the attack, when under his very eyes an eruption of urticaria took place on the skin and soon spread over the whole body. The throat symptoms subsided in a few hours. An hour after seeing this patient M. Sevestre was called to see her son, aged 4, who had also been suddenly seized with suffocative dyspnœa. Exactly the same train of events was observed as in the mother. It turned out that both of them had eaten mussels at luncheon.—*Brit. Med. Jour.*

ZONA IN DIABETES.

Though there have been many injuries and disturbances of the nervous system recorded in diabetes mellitus, it still remains a matter of debate in Professor Vergely's opinion how far they are to be attributed to a central and how far to a peripheral origin. In the cases of neuralgia it has been held that the absence of local heat and vesicular eruption excluded all idea of neuritis. Some good authorities, among whom were Ziemssen, Charcot, and Buzzard, did not agree with this, but the first adequate pathological demonstration of the effect of neuritis on the diabetic nerves was made last year by Dr. Auché, of Bordeaux. The myeline was seen to be vacuolated and broken up, the axis cylinder had disappeared. The clinical symptoms had been sometimes œdema, sometimes glossy skin, perforating ulcer, malnutrition of the nails, and even gangrene. But among them zona had not been mentioned, and zona was almost certainly the result of a neuritis. The parasitic theory of its origin, which Dreyfous and Letulle—following Landouzy—had put forward two years ago, had been imperfectly supported, and it is necessary to reconsider the constitutional conditions of its origin. It was very rarely referred to as associated with diabetes in the special essays on either complaint. Professor Vergely brought forward two cases of diabetes mellitus, in which it had a marked feature, and which had been under long observation. The first was a man aged fifty-four, of powerful build and healthy history and habits. In middle life he began to get uncomfortably stout, and some sugar was noticed in his water. In May 1885, he had sharp neuralgia of the right side of his forehead, which was followed by a well-marked eruption of frontal herpes, which for at least ten days gave acute burning pain, and left a

deep scar along the course of the left supra-orbital nerve. The skin in this region thickened, and became gradually insensitive to pain, though remaining normally sensitive to touch and temperature. The amount of glycosuria did not greatly increase, but was complicated with albuminuria; all food was rejected; and the patient gradually sank into a uræmic condition, and died of exhaustion. The second case was that of a woman of forty-three, who had lived an active life, of good health till about thirty-seven, and since then had had much mental distress, and had begun to show signs of diabetes. When the percentage of sugar had become considerable, she got an acute neuralgia in the lesser right sciatic nerve with an abundant eruption of zona. The scars which were left were distinctly more sensitive to touch and to pain. As to what may be the temporary or permanent effect of the eruption on the secretion of sugar, and the best means of prevention and cure we have still much to learn from wider observation.—*Le Progrès Méd.*, September 26, 1981.

SPONTANEOUS AMPUTATION OF THE TOES IN SYPHILIS.

Viennois, of Lyons, reports (*Ann. de Derm. et de Syph.*, Nos. 8 and 9, 1891) a case of moist gangrene of the toes which he attributes to the effects of inherited syphilis. The history given by the patient, a man, aged forty-three, was that at four years of age he had had convulsions followed by paralysis, which at first affected all the extremities. This was recovered from except that the left leg remained somewhat contracted and the knee slightly bent. At eight years of age a red patch appeared on the lower part of the left leg, and finally broke into a sore. This began in the month of February and lasted until June, under medical treatment. He then remained well until, at thirteen years of age, another red patch appeared near the site of the former one. This also was in the winter, and the patch broke down forming a sore, which healed in about sixteen months without medical treatment. Again there was an interval of good health until he was twenty, when two more patches similar to the preceding formed on the same leg, and again in the winter, ran a similar course, and healed spontaneously in the following summer. From this time he remained well for twelve years, when at the age of thirty-two, the patient having in the mean time become much reduced in circumstances, red patches appeared on the backs of the second and third toes of the left foot. These at first behaved like those on the leg, but the resulting ulceration, instead of healing, continued to spread slowly for ten years, at the end of which time (October, 1890) he was first seen by Viennois, who found that the second and third toes had disappeared. The patient said they had dropped off four years previously. An offensive, sloughy, inflamed ulceration occupied the anterior fourth of the plantar surface of the foot, the plantar surface of the remaining toes, and part of the dorsum of the foot. Viennois diagnosed inherited syphilis because he had "precise information" that both the man's parents had had syphilis, the mother having had among other tertiary affections a perforation of the palate, and from the lesions above described, which he considered to have been gummata. The patient himself had never suffered from any venereal disease, and his wife and only child were healthy. Under specific treatment carried out at the man's home where the conditions were insanitary, only temporary improvement took place. He was then admitted into hospital under the care of Ollier, and there, under iodide of potassium and tonics internally and salol locally, cicatrization was complete at the end of a month. Viennois also refers to other cases of gangrene, both moist and dry, been recorded by various authors in connection with syphilis.—*Brit. Med. Jour.*

"TIC CONVULSIF."

Dr. Berthold Beer publishes in a Vienna journal a contribution to the treatment of "tic convulsif." He begins by stating the well-known fact that partial convulsions or involuntary muscular contractions are no rare occurrences. Clonic convulsions are frequently observed in a small lateral portion of the inferior part of the orbicularis palpebrarum. They often last for some minutes, and are generally symptoms of conjunctivitis or of slight pathological changes in the region of the palpebral margin, and in the ducts of the Meibomian glands. Many authors call these, as well as the clonic contractions of parts of a muscle, such as occur frequently in the bicipital groove, in the abdominal muscles, and in other parts, fibrillar muscular convulsions. The name is, however, really only applicable to the fibrillar convulsions after anæmia, which Sigmund Mayer described, and which may be well observed in the tongue and facial muscles of recently decapitated animals. In clonic convulsions of this kind the peripheral source of the

affection may be recognized by the dilatation and congestion of the neigboring blood vessels and by a slight inflammation of the muscular tissue. In this form of convulsions an anatomical alteration of the peripheral tissues near the affected muscle is found, but very frequently contractions of the palpebral muscles are observed, which may be considered merely exaggerations of the normal palpebral function. The twitching occasionally extends to the facial and frontal muscles, so closely connected with the palpebral muscles, and corrugation of the eyebrows and elevation of the alæ nasi, or of the angle of the mouth occurs. The mechanism of these contractions, which represent the simplest form of tic convulsif, and which, being merely considered bad habits, seldom come under medical observation, is of a reflex nature, resembling involuntary action. Other cases of tic of the kind which comes most frequently under medical observation may obstinately resist every treatment, until it is possible to remove the original cause of the attacks. This is generally situated in the nasal mucous membrane, the palate, the periosteum of the facial bones, or the alveolar margin. Cocaine is a most valuable remedy in such cases. In rarer cases the facial epidermis provides the means whereby the tic extends over a larger area, and in one case of this kind slight valvular dilatations in the infra-orbital region contributed to the greater intensity and frequency of the attacks. In such cases the usual and easily excited reflex and automatic movements may be also considered, as they may be the ultimate cause of the attack. This is especially the case when the affected muscles, from a cerebral or peripheral cause, have been temporarily paralyzed or weakened in their functional capacity. In such muscles reflex and automatic impulses, such as operate in sneezing, laughing crying, expressions of fear, and others, may be stronger than in healthy muscles. An appreciable disturbance of sensibility may not therefore be present, and yet local anæsthesia of the nasal mucous membrane may cut short the attack, and tic which has been caused by cerebral conditions may be improved by peripheral treatment. —*Lancet.*

"Eureka!" cried the young doctor.

"Why, what's the matter, my dear?" asked his wife.

"My fortune is made. If Pasteur and Koch can cure consumption and hydrophobia, why can't I take some Jackass virus and down asininity?"—*New York Herald.*

SURGERY.

THE OPERATIVE TREATMENT OF IRREDUCIBLE LUXATIONS OF THE THUMB.

Dr. Montez states that the operative treatment of this trouble has attracted but little attention, and some authorities have condemned surgical interference. Dr. Mortez, however, thinks that these patients should enjoy the benefits of antiseptic surgery, for the sake of improving the appearance of the thumb, even when its functions are not much interfered with. As regards the methods of operation, arthrotomy is not of itself sufficient to effect reduction, and section of the lateral and capsular ligaments has proved of no service. Resection alone is of value. The incision should be anterior and made over the head of the metacarpal bone; the periosteum and capsular sheath are detached, and the head of the bone excised. If the patient is young the periosteum should be abraded to avoid periosteal proliferations and anohylosis. —*La Tribune Medicale.*

STAB-WOUND OF THE SPINAL CORD.—A STUDY OF BROWN-SEQUARD'S PARALYSIS.

Neuman (*Virchow's Archiv.*, Bd. cxxii., Hft. 3), reports five carefully observed cases of wounds of the spinal cord at various levels, involving partly one-half of the cord and also the nerve roots. Only two cases corresponded with the genuine Brown-Sequard transverse hemisection. In one case oblique division was found affecting only one-half of the cord, although the marked hæmorrhage at the point of injury and the level of the wound presented the picture of a complete transverse separation. A change in the muscular sense, after a long time, was demonstrable only in one case, confirming Erb's assumption of a non-decussating course of the corresponding nerve tract. Ataxia was present in one case shortly after the injury. In every instance the victims fell to the ground immediately, some becoming unconscious. The loss of blood was generally considerable. There was high fever in two cases, without suppuration, having occurred during the healing process. The writer believes this was due to the injury of the nerve centres. In one case there was remarkable warmth of the body twenty-four hours after death, although it was winter. Injury of the anterior horns or of the fibre tracts, immediately after their exit, was suggested in two cases, owing to the interference with the growth of the limbs, and especially a lack of development of the

bones on the paralyzed side. In four cases the healing process progressed without complication, and in the course of time improvement took place without further treatment. In the opinion of the author, a cautious galvanic or faradic treatment is indicated, and may prove of value after healing of the wound. The absence of secondary and neuritic degeneration essentially differentiates these incised and punctured wounds in their course and especially in prognosis, from inflammatory and pressure lesions of the cord which present a similar appearance.—*Centralbl. f klin. Med., No. 39, 1891.*

SUCCESSFUL RESECTION OF GANGRENOUS BOWEL FOR INCARCERATED INGUINAL HERNIA.

Stern (*Berliner klin. Wochenschr.*, No. 41, p. 1011) has recorded the case of a woman, sixty years old, who came under observation after having presented, for a week, symptoms of intestinal obstruction, dependent upon an incarcerated inguinal hernia. An incision over the most prominent portion of the swelling in the right inguinal region confirmed the diagnosis and revealed the existence of peri-hernial suppuration. The incarcerated bowel was found gangrenous and perforated. Most careful antiseptic precautions being observed, the incarceration was relieved.

The healthy intestine, on either side of the gangrenous area, was firmly grasped by an assistant and a section of bowel, about two inches long, was removed. The free margins of the remaining intestine were approximated by means of Lembert sutures, the first suture being applied at the point furthest from the mesentery, the distance being progressively halved with each succeeding suture. After satisfactory approximation, the wound was closed and dressed. The subsequent course of the case was surprisingly uncomplicated. Twenty-five days after the operation the patient was able to resume her household duties.

MEDICAL CHESTS ON RAILROADS.

On all French railroads, even those of slight importance, having a physician in charge, there are medical chests on the trains. A principal physician, at a salary of $1,000, is supposed to supervise all the roads in France. This appointment has been abrogated, as no one man can inspect all the roads. Each company now has its own physician and surgeon to do the inspection formerly done at the expense of the State.—*La France Medecale.*

SURGICAL FILARIOSIS.

Moty, (*Revue de Chirurgie*, January, 1892) reports six cases of lymphatic varix in the groin and scrotum, due to the presence of filariæ in the blood and lymph. The patients all of whom had resided in French colonies, came under observation at the Val-de-Grace. This inguino-scrotal swelling, it is thought, may frequently occur amongst those who have returned to Europe after a sojourn in any of the districts infected by the parasite, the nature and origin of the affection being probably often overlooked. Moty discusses at length the serious questions relating to filariosis, and at the end of his paper gives the following summary: "(1) Filariosis is an aseptic parasitic affection. (2) It is due to the presence in the body of the filaria sanguinis hominis. (3) It is of very frequent occurrence in most of the French colonies, including New Caledonia. (4) It is most frequently manifested by dilatation of the glands and lymphatic vessels of the groin and spermatic cord. (5) The pathology of the filarial phenomena seems to consist in the irritative action of the filariæ and their embryos, both being nomadic on the cellulo-lymphatic system. (6) It is possible to base the diagnosis of filarial lesions on clinical data, but it ought to be confirmed by examination of the blood. (7) No results have yet been obtained from internal remedies in the treatment of filariosis. (8) Attempts at external palliative treatment cannot be strongly recommended; excision of the hypertrophied structures is indicated when their size causes much inconvenience. (9) In the course of such surgical interventions, living or dead adult filariæ may be removed with the diseased tissues."—*Brit. Med. Jour.*

INTESTINAL OBSTRUCTION FROM MECKEL'S DIVERTICULUM.

Oderfield publishes in the *Gazeta Lekarska* the particulars of an operation for acute obstruction of the bowel caused by the presence of Meckel's diverticulum. The distal end of the diverticulum had become attached to the mesentery, thus forming a loop through which a coil of intestine had slipped. The excessive formation of gas in the bowel had compressed the knuckle of intestine and caused it to become fixed. The author, in performing laparotomy, freed the incarcerated coil by separating the adherent end of the diverticulum, and to prevent a relapse he removed the latter by a circular incision at its base. The patient recovered. Oderfeld also discusses the mechanism, pathology, and

the various causes of this form of obstruction, and states that no case is known in which the cause of the obstruction was diagnosed before the operation. Two symptoms, however, possess a certain diagnostic value. When obstruction occurs in a patient suffering from harelip or some other congenital deformity, the former is probably due to the presence of Meckel's diverticulum. It is also important to have the history of the patient's early life. When during the latter an unbilical fistula has existed with fæcal discharge, which, however, has occasionally healed voluntarily, the same conclusion may be drawn.—*Lancet.*

SURGEON AND PATIENT.

Our attention has been directed to the case of Bachelor *versus* Gore, which came before the Supreme Court of New Zealand at the end of last year, and will be found fully reported in the *Otago Daily Times* of Decem- 23d, 1891. The following are the chief facts of this singular case, which was one of a claim on the part of Dr. Batchelor, the plaintiff, for a fee for medical attendance, and a counter-claim on the part of his patient, who was the defendant, for damages for alleged unskilful treatment. Mr. Gore, a contractor, aged 55, after having suffered during four years from pulpy disease of the right knee, for which he was first treated by Dr. Batchelor, and subsequently on and off by other practitioners, returned to the plaintiff in September, 1888, deteriorated in health and the diseased joint much disorganized. The plaintiff, convinced that it would then have been useless to persevere with expectant treatment, in which opinion he was supported by other experienced surgeons, excised the diseased joint. Although it is not clear whether amputation was proposed as being a much more promising method, there can be no doubt, from the evidence, that the patient absolutely declined to lose his limb. The age and unhealthy condition of the plaintiff being considered, it seems to have been a somewhat bold step on the part of Dr.Bachelor to undertake excision in this case. Notwithstanding the unfavorable condition, however, the correctness of his view was justified by the results, as it was shown by strong medical testimony, and also by the admissions of Mr. Gore himself, that the operation had been followed by complete success.

Firm union of the bones was much retarded, but this seems to have been unavoidable, as the patient, who was a restless man, insisted of sitting up in bed on the fourth day after the operation, and after the first week reclined daily in an arm-chair. The plaintiff, in cross-examination, acknowledged that he was able with his saved limb to descend steep embankments, to attend race-courses, and to visit mines. He is to be seen daily, it is stated, walking about the streets with a light stick, apparently quite restored to health, and able to follow his usual vocations.

After a brief consultation a verdict of three-fourth of the jury was returned for the plaintiff, awarding the full amount claimed. It is to be regretted that the jury did not adopt a suggestion of the plaintiff's counsel, and state, as they might justly have done, that there was no ground whatever for Mr. Gore's course of conduct. This is one of the worst instances of the "ungrateful patient" that we have met with, and we feel sure that the profession in this country will join their colleagues in New Zealand in congratulating Dr. Batchelor on the skill he has shown in this case, and on the result of this vexatious and unreasonable action.—*Brit. Med. Jour.*

ABORTIVE TREATMENT OF URETHRITIS.

Dr. J. W. S. Gouley. in a series of articles on "Disease of the Urinary Apparatus" being published in the *M. Y. Medical Journal,* speaks as follows of the abortive treatment of urethritis: "The treatment of acute urethritis was for a long time based upon erroneous notions of its nature, and directed to the substitution, as it was believed, of a simple, inoffensive, for a specific phlegmasia. This treatment, suggested in 1780 by Simmons, and afterward largely employed by Ricord, Diday and others, consisted of urethral injections of nitrate-of-silver solution (ten, fifteen or twenty grains to the ounce), and was named the abortive, to distinguish it from the methodical treatment. This supposed quick way was as delusive as it was alluring, alike to patients and to physicians, for it seldom cut short the attack of urethritis, and besides the great distress it caused, was often productive of grave effects upon the urethra and adjacent parts, the first effect being a super-acute urethritis, then peri-urethritis, lympangeitis, sometimes prostatitis, trachelocystitis, gonecystitis, orchitis, etc. Inasmuch as this too heroic treatment is still, though very rarely, recommended, it was thought necessary to give this note of warning to younger members of the profession against the employment of means which not only fail to remedy, but serve to aggravate the affection."

MECHANISM OF FRACTURES OF THE PELVIS.

Areilza (*Centralb. f. Chir.*, No. 41, 1891), who, as medical officer to large mines in the northwest of Spain, has had much experience of pelvic injuries, compares the features of fracture produced in the living body through injury with those of fractures artificially produced on the pelvis of the cadaver by a machine so constructed as to compress the bones transversely between a fixed and a movable plate. The following effects, it was found, are produced by gradually-increased lateral compression of the pelvic girdle; flattening of the iliac bones and increase of the antero-posterior diameter of the pelvis; separation of the bones of the pelvis and disruption of pubic symphysis and of the sacro-iliac synchondrosis; fracture of the pelvic arch, generally through tho horizontal ramus of the pubes; fractures near the symphysis and sacro-iliac synchondroses, and disorganization of these articulations. The following conclusions have been drawn from the results of numerous experiments, and from observations of thirteen cases of fractured pelvis, in the majority of which the urethra was wounded: (1) In injuries of the pelvis caused by pressure applied simultaneously to both sides, one iliac bone only is as a rule flattened and displaced, the other remaining unaltered; symmetrical quadruple fracture of the pubes and ischium on both sides is of very rare occurrence. (2) The nature of the injury is influenced to a considerable extent by the elasticity of the pelvic girdle; in consequence of this elasticity the bones regain their previous form and position after having been subjected to enormous pressure, so that in the living patient, and even on examination after death, it is difficult to determine what had been the nature and extent of the changes produced at the time of the injury. (3) Of the injuries of the soft parts, the more important are those involving the urethra. These are usually localized in the membranous portion. (4) Cases of complete laceration of the urethra and of perforation by splinters of bone being excepted, the most frequent injuries are caused by teasing of the aponeurotic structures attached to the margin of the pubic arch, as a result of displacement of the pubic bones, one of which often over-rides the other; these injuries consist in small lacerations, which rarely involve the whole thickness of the urethral wall, and which give rise to ecchymoses, hæmorrhage from the urethra, and, after a time, stricture. (5) The urinary effusion after injury from transverse pressure does not accumulate in the perineum, but passes upwards into the cavity of the pelvis, and thus constitutes a very grave condition, which should be treated by an early incision in the hypogastric region.—*Brit. Med. Jour.*

OBSTETRICS.

DEATH AFTER LABOR FROM TORN PERITONEAL ADHESIONS.

A. Holowko (*Zeitschr. für Geburtsh. u. Gynäk.*, vol. xxi, 1891, pt. 2) relates the case of a pregnant woman who suddenly felt pain in the abdomen after jumping when eight months pregnant. The temperature rose to 104° in a few days. Tonic contraction of the uterus was checked by warm baths and hypodermic injection of morphine. A few days later the patient was delivered, and rapidly became worse. The pulse increased to 140. No hæmorrhage occurred after the expression of the placenta, but the patient died in an hour. At the necropsy bleeding and torn adhesions were found between the ascending and transverse colon. There was no sign of sepsis, but the peritoneal cavity contained much blood. Tearing down of adhesions occurs when women who have undergone hysteropexy become pregnant.—*Brit. Med. Jour.*

MENSTRUATION AND LACTATION.

It is a generally received view that the supervention of menstruation during the period of lactation is prejudicial to the quality of the maternal milk supply, and therefore detrimental to the nutrition of the child. Most practitioners will probably state as a matter of observation that menstruation unfits the mother as nurse by reducing the quantity of the milk in addition to rendering it more "watery." In order to ascertain the real effect of menstruation on the quality of the milk, Dr. Schlicter has made a series of analyses which seem to show that the current belief is founded on defective observation. In addition to careful examination of the composition of the milk during and after menstruation, he had the child weighed and its general condition noted at and after the same period. He reports that in respect both of casein and fat, the milk secreted during menstruation compared favorably with that furnished prior to that date. The differences observed, moreover, in no case equalled those which occur in the milk of the normal healthy female at various periods of the same day; hence he declines to attach any importance to them.

He concludes by asserting that menstruation either before or after the sixth week can have no deleterious effect on the offspring.—*Med. Press.*

GYNÆCOLOGY.

THE USE OF THE ACTUAL CAUTERY IN GYNÆCOLOGY.

Dr. V. Stolypinski, in an article in a Russian medical journal, strongly recommends the more frequent use of the actual cautery in gynæcological operations, as, for instance, in the destruction of fungating cancer, for the arrest of bleeding from pedicles, and for the removal of small tumors. He uses it in the removal of the vaginal portion of the os, when required, for malignant disease, and recommends it on account of its easy application, the slight loss of blood, and the simple after-treatment. He reports only one case with an unsatisfactory result, obliteration of the os being found at a subsequent confinement.—*Lancet.*

INFLUENZA AND PELVIC CELLULITIS.

Sigmund Gottschalk (*Centralbl. f. Gynäk.*, No. 3. 1892) noted, in the same publication in January, 1890, the frequency of endometritis in influenza. It is associated with free hæmorrhages, and it is a common complication in the epidemic now raging. He has also seen three distinct cases where parametritis or pelvic cellulitis developed in the course of influenza. In two cases there was no evidence that the pelvic disease had previously attacked the patient. The first patient was a young girl aged 21, evidently a virgin. Eight days after the period she caught influenza, and profuse metrorrhagia occurred. For three weeks she suffered badly from bronchitis. Pains in the right iliac fossa set in during the first week; the flooding lasted for a fortnight, and was followed by free discharge. A very extensive hard swelling occupied the right side of the pelvis and pushed the uterus to the left. The second patient was 22 years old. As in the first case, severe metrorrhagia set during influenza. Then, when the fever was moderate, hypogastric pains occurred, and a characteristic parametritic deposit developed in the pelvis. The third case differed from the others, for the patient had suffered many years before from left parametritis. She was taken ill with influenza on January 6th, 1892. The temperature rose very high, and parametritis developed in the old scar. By the sixth day the patient began to improve, and a very extensive infiltration was detected in the left broad ligament. In none of these cases was there evidence of peritonitis or of inflammation of the tubes and ovaries. The influenza virus may, Gottschalk observes, directly attack the pelvic connective tissue. Otherwise, the parametritis must be secondary to the endometritis—a much more frequent and very distinct complication of influenza. The poison must travel through the lymphatics of the cervix, and not along the tubes.—*Brit. Med. Jour.*

TOTAL EXTIRPATION OF THE UTERUS FOR MALIGNANT DISEASE.

Gusserow (*Berliner klin. Wochenschrift*, 1891, No. 71) reports sixty-seven cases of total extirpation; in four of these laparo-vaginal hysterectomy was performed, with three deaths. He regards the latter operation as a dangerous one, to be undertaken only under exceptional circumstances, where the vagina is unusually narrow, or carcinoma is complicated with fibro-myomata. The total mortality 10.4 per cent. Of fifty patients who had been operated upon over a year before, sixteen were free from recurrence (one after the lapse of eight years), eleven had died from the disease, and one from pyelonephritis; eleven had a recurrence, and eleven were not heard from.

The writer believes that statistics will only be improved by early resort to the radical operation, at a time when the diseased tissue can be thoroughly removed. He rejects cases in which the vagina and broad ligaments are involved. Limitation of the mobility of the uterus (the patient being anæsthetized) by indurations in the parametria should be a contra-indication, even if the operator is not positive regarding their malignant character. By operating upon such doubtful cases vaginal hysterectomy is brought into disrepute. His strict adherence to this rule led the writer to operate upon only five per cent. of the cases treated by him.

THERAPY IN ALBUMINURIA AND NEPHRITIS OF PREGNANCY.

Mynlieff writes: (*Der Frauenarzt*, Heft 8, 1891) Prophylaxis aids us but little in preventing this unfortunate occurrence. We can recommend frequent warm baths, the wearing of woolen underwear, and prevention of all forms of excitement. If a chronic nephritis exists, the danger to the mother becomes so great—statistics show a mortality of eighty-four per cent.—that the induction of

premature labor is demanded. If an occasional albuminuria occurs during pregnancy, no treatment need be adopted besides unusual care and vigilance; but where a nephritis exists patient should be placed upon a strict milk diet. This often effects wonders; the quantity of urine becomes increased, the albumen disappears and eclampsia does not occur. If symptoms arise, warm baths and subcutaneous injections of pilocarpine do good service. Gramm and Schröder recommend the employment of the salicylate of theobromine (diuretin). Mynlieff believes that if a nephritis occurs in the early months of pregnancy, in a previously healthy woman, the induction of premature labor is indicated. When, however, it appears in the sixth or seventh month, then interference with the gestation is contra-indicated, except when very serious symptoms develop, such as dropsy, dyspnœa, etc.

PÆDIATRICS.

INFANTILE MASSAGE.

The *Medical Mirror* says: The young infant, which is restless shortly after birth as a result of its inability to accommodate itself to its new environment, should be given the benefits of massage not less than twice a day. The activity of the skin is thus developed, the circulation of all the external tissues is improved, and the child, if the massage is applied judiciously, is rendered restful. Many a time it will gently doze away into that land of Nod which is of such value in building up its force and strength under the gentle manipulations of the soft and tender hand. Not only is its nervous system soothed and comforted, but growth is stimulated for the reason that the growth is made perfect when the rest secured is more perfect, and when there is the greatest activity in the action of the component parts of the anatomy. An active skin, where exosmosis is most perfect creates an endosmosis between the tissues and the absorbents; the food which is partaken of by the child is more actively digested, more industriously appropriated, where there is that perfect activity of all the tissues which can be best accomplished by judicious massage.

That *bete noir* of the nursery—constipation—can be more thoroughly and permanently relieved and avoided by massage over the abdominal region than by any other method. The mechanical manipulation encourages peristalsis directly, and also urges onward, independently of the intestinal contractions, the contents of the intestine. The gentle rubbing of the liver encourages its action, and the secretions are less liable to accumulate. The effect upon the internal muscular system and the muscular coats of the intestine and of the various tubes to the secreting glands, from the stimulus furnished to the exterior is pronounced. The muscular system is 'a complete whole, and thorough exercise of the bulk of the system develops the working power of its individual parts, so that in massage in infants we must have, if applied thoroughly and well, a most potent factor for good.

TREATMENT OF DIPHTHERIA.

Smith (*The Practitioner*, No. 282, p. 430) has successfuly employed carbolic acid by continuous inhalation in seventeen cases of diphtheria. He ascribes the good results largely to the method of application. The patient is placed in bed, lightly clad and made to maintain the recumbent posture. Over him is placed a tent, made of a sheet, closed on all sides except in front. Cloths, about a foot square, soaked with a mixture of carbolic acid, one part, oil of eucalyptus, one part, and turpentine eight parts, (or less, according to indications), are hung about the patient, while the surrounding air is constantly kept impregnated with the vapor of steam. The cloths are to be re-soaked as they become dry. The patient should breathe through the mouth. If necessary, the nostrils may be loosely plugged with cotton-wool. The inhalations do not counter-indicate the employment of other therapeutic measures. Should there be depression, alcohol, digitalis, belladonna, or ammonia may judiciously be administered.

LITHOTRITY IN BOYS.

L. P. Alexandrow (*Deutsche Zeitschr. f. Chir.*, Bd. 32, Hft. 5, No. 6, 1891) has performed lithotrity thirty-two times on boys from one to fourteen years of age in the Olga Hospital for children, at Moscow. In twenty-seven of these cases the operation was successful, the little patients making excellent recoveries. In the remaining cases death occurred, in three from injury to the urethra during the operation, and in two from causes unconnected with the surgical procedure. Alexandrow's experience leads him to the following conclusions: Lithotrity is indicated in boys when the urethra is sufficient to allow the passage of a small instrument (No. 14) and the diameter of the stone does not exceed from 2 two 2½ centimetres (¾ inch to 1 inch). In other cases better results will

be obtained by suprapubic cystotomy with consecutive suture of the bladder.—*Brit. Med. Jour.*

THE SUB-MEMBRANOUS TREATMENT OF PHARYNGEAL DIPHTHERIA.

At the recent meeting of the American Pædiatric Society, Seibert (*New York Medical Journal*, Dec. 12, 1891)gave the results of fifty additional cases treated by sub-membranous injections of chlorine water. The ages of the children varied from six months to fourteen years. In forty-four cases the injections had been efficacious, in three there had been slight improvement, and in three none. Only four patients died, all of them being very severely affected, and evidently fatally so under any form of treatment. Recovery had taken place in from one to eight days.

The satisfactory results of the treatment were shown in a lowering of the temperature, improvement in heart's action, and disappearance of the false membrane. The chlorine water was the officinal preparation, freshly made, and was injected quite deeply so as to reach the sub-mucous tissue. In the majority of cases the author had found it necessary to make only one injection. A suggestive fact is embodied in the statement that neither paralysis nor nephritis had occurred in any of the cases that recovered.

HYGIENE.

ARTIFICIAL TEETH FROM A HYGIENIC POINT OF VIEW.

It is common experience amongst dentists that a very large majority of artificial dentures are discolored and by no means devoid of unpleasant odor. This lack of cleanliness, which arises sometimes from neglect, but very often from want of instruction on the part of the dentist as to the necessary *modus operandi*, is a fruitful cause of inflammatory conditions. Débris of food mixed with saliva and mucus accumulating on a plate rapidly undergo decomposition, with the result of irritating the mucous membrane and producing a general inflammation of the oral cavity. The oral secretions become altered and vitiated, so as to cause dyspepsia, and caries of the remaining natural teeth is set up, which proceeds with great rapidity, especially in "clasp" dentures, not from the friction, but because the inside of the clasps generally escapes the brush. The materials used in the construction of artificial dentures differ widely in their effect upon the tissues with which they come in contact. A larger number of inflammation of the oral tissues occur where vulcanite is used as a basis than with gold or other metals, and so prevalent is this inflammation in the case of vulcanite that it has received the distinctive appellation of "rubber sore-mouth." Several reasons have been assigned for the effects produced by vulcanite. Nearly all this material is colored with mercuric sulphide (vermilion), which ingredient has been accused of being the cause of trouble; but an exhaustive investigation did not substantiate this view, one particular point being that "rubber sore-mouth" often occurred where black rubber was used, which contains no vermiiion. The porosity of vulcanite, especially when not sufficiently vulcanized, renders it liable to retain deleterious material if not kept scrupulously clean.—*Lancet.*

COFFEE-TEA.

Mr. William Sowerby, the veteran and distinguished Secretary of the Royal Botanical Gardens, favors us with the following note on his pregnant suggestion for adding to the number of alkaloid beverages by the introduction of coffee-tea: When walking in the Gardens of the Royal Botanical Society, Regent's Park, and noting the extent of the collection of living medicinal and economic plants of all climes and countries there brought together in one spot, it must have occurred to all of us how very small a number of plants, out of the vast store which Nature has provided, man has bound to his service, and the yet fewer he has taken the trouble to cultivate. During the march of the last half century (in science, medicine, mechanics, steam, and electricity) how little has been the gain from Nature's stores. The artificial culture of cinchona is, perhaps, the most noted of the few. Again, any step in eating, drinking, dress, is so governed by habit or fashion that he must be a bold man who tries to turn the current. This is illustrated in tea drinking. Perhaps there is no one habit so universal; each people has its peculiar tea or closely allied beverage, and most of these have continued the same for many ages. In one it is cocoa, in others, coffee, and in many, tea; in a few special quarters of the globe nothing but *matè* is thought fit to drink, but in only one small district is coffee-leaf tea used. Now we all know that these beverages are found by man to be pleasant and agreeable to him by reason of their containing a peculiar princi-

ple called *theine;* but yet we do not always select for our use the part of the plant containing the largest percentage of *theine*, or cultivate the special plant with a view to afford us the most valuable part. For example, in coffee the leaves are said to contain 1.26 of theine, and the berries only 1.0 per cent, and yet over 110,000,000 of men use the berries, and only 2,000,000 the leaves of coffee, although 500,000,000 use the leaves of tea. Now the cultivation of coffee berries is very trying, precarious, subject to attacks of blight and unfruitfulness—in fact it follows the general line that the produce of fruit by cultivation is far more open to accident than that of the leaves, and very probably good crops of coffee leaves could be obtained at small cost in countries and localities where it would be risky or even impossible to produce berries. Here is a case open to a vast variety of people to solve, for there can be no reason why coffee leaves may not become a valuable item of culture in our warmer colonies and many parts of the world. The one most difficult item to move is to create the demand. Once start the fashion for "5 o'clock coffee-leaf tea," and the thing is done, and many a fortune made. As to the peculiar flavor of coffee-leaf tea much dedends on the manipulation of the leaf after it is taken from the plant. At the Botanic Gardens a variety of flavors have by treatment been produced from leaves off one plant, the general flavor being a kind of combination of coffee and tea so as to get both in one cup.—*Brit. Med. Jour.*

THE DISSEMINATION OF TUBERCULOSIS BY PASSENGER TRAFFIC ON RAILWAYS.

Incited thereto by Cornet's investigations, Prausnitz (*Central. für Bakt. u. Parasit.*, Sept. 18, 1891) investigated the dust taken from passenger trains for the bacillus tuberculosis. He chose for his experiments through-going cars, which were most used by consumptives. After the arrival of the train from Berlin in Munich, he swept up the dust collected underneath the compartment carpets of the selected cars, and mixed it up in a sterilized porcelain capsule, mixed a part of it in sterilized distilled water, and injected it into the peritoneal cavity of guinea-pigs. In this way twenty guinea-pigs were injected with the dust taken from ten compartments of four cars on five days. Of these twenty guinea-pigs, five developed tuberculosis. The dust used in these five cases all came from two cars. The experiments showed that the dust of railway cars, in which one would presume that large numbers of tubercle bacilli might be present, for the most part contains none of these germs, and even in the cars which are the longest on the road the dust contains but few. "The ordinary method of cleaning out railway passenger cars suffices to keep them so free of tubercle germs that danger to the traveling public in this respect seems to be excluded."

MEDICAL CHEMISTRY.

MYRTOL—SO-CALLED ESSENCE OF THE MYRTLE.

An anonymous writer in the *Gazzétta Chimica Italiana* states that the name myrtol, as applied to the essential oil of myrtle, is improper, since the oil is found by late investigations to be composed of two substances, one of which is an isomer of turpentine, and the other an oxygenated body, an isomer of camphor.

TESTING FOR SUGAR IN URINE.

Dr. G. Vulpius, of Heidelberg, suggests a method of insuring the correctness of the conclusions derived from applying Trommer's test to urine suspected of containing sugar (*Pharm. Post*, 1892, 7).

It is well known that the urine contains some normal and may contain abnormal constituents which will, at least under certain circumstances, cause a reduction of the test solution (Fehling's) with production of red cuprous oxide. Such substances are: uric acid and creatinin, when present in large quantities; milk sugar, allantoin, mucin, pyrocatechin, hydrochinon, urobilin, biliary pigments. The same reduction occurs after the administration of benzoic, salicylic, or oxalic acid, glycerin or chloral. Hence it is always advisable to employ, alongside of the alkaline copper sulphate reagent, a second one which is not liable to the same drawback The most preferable are: the fermentation test, the polariscope test, or Nylander's alkaline bismuth tartrate solution.

On the other hand, it often happens that, though urine contains sugar, yet cuprous oxide fails to separate in consequence of the presence of certain compounds interfering with its precipitation. Such compounds are: ammonium salts, creatin, albumen, and products derived from the latter by the caustic alkali of the reagent itself. The interference of ammonium salts may be overcome by heating the urine with caustic alkali until all

the ammonia has been dissipated. In the presence of the other substances a separation of cuprous oxide may often be promoted by suitably diluting the urine after it has been boiled with the reagent, or by cooling it, or in other ways.

The non-appearance of a reaction, when Fehling's test is applied to a sample of urine, is, therefore, not an absolute proof of the absence of sugar. But there is a very simple method to make the result certain, as will be seen presently. If the reaction is prevented by the presence of bodies such as those before mentioned, it will be readily understood that, even if a small quantity of glucose solution were purposely added to the urine, the separation of cuprous oxide would still be prevented. Of course the quantity of glucose thus added must be properly regulated, and the test is best made in the following manner: Heat two test tubes, each containing 5 cc. of Fehling's solution, until the latter boils, then add to one of them 1 cc. of the suspected urine previously diluted with an equal volume of water, and to the other 1 cc. of the same urine previously diluted with an equal volume of a 1 per cent. aqueous solution of glucose, and again apply heat until the contents of the test tubes boil. If there is now still no change in the two liquids, it may safely be concluded that there are substances present which interfere with the reduction of the copper salt. In such cases, then, recourse must be had to other reliable sugar tests. If, however, there is a reduction in the test tube to which glucose solution was added, this proves the absence of substances interfering with the test; hence, if no reduction took place in the test tube to which the urine was added, the latter may be safely regarded as free from sugar.

HYGROSCOPIC CHARACTER OF CAMPHOR AND THYMOL.

In the course of a physiological investigation of the irritability of a fungus, Professor Errera was led to the conclusion that camphor possesses a considerable hygroscopic capacity, which is not shared by thymol. Accurate experiments by Herr Clautriau have substantiated this opinion, and show that whereas 40 grains of camphor will absorb 0·054 gm. of water from air saturated with aqueous vapor at 16° C., thymol does not perceptibly increase in weight under the same condition. The absorption of water by camphor must be purely a physical phenomenon, since the condensed moisture is readily removed even under the influence of anhydrous camphor. The dry substance, although it attracts a comparatively small quantity of water, does so with such energy that its weight increases even in air containing but little moisture.

A GENUINE TEXAS SHOTGUN.

Meyer Brothers' Druggist, publishes the following: Below find a correct copy of a prescription handed me to be filled not long ago. Please publish as a genuine shotgun. If any of the boys can beat it I would like to hear from them through your columns:

It ought to make a hit!

NEWS AND MISCELLANY.

HOW TO IMPROVE THE POSITION OF THE PROFESSION.

Dr. Orlando Jones, in his presidential address to the Harrowgate Medical Society, took for his subject the Possibility of Improving the Position of the Medical Profession. He infers from the writings of Pliny, the medical learning of Druids, and from those of Ptolemy, that their wealth was equal to their learning. Such being the honored and happy case of the ancient representatives of medicine, he argues that it should not be otherwise with the present practitioners. He does not look for any amelioration in the position of the profession by attacking the Council of the Royal College of Surgeons, or by a mere increase in the direct representation of the profession in the Medical Council. These are his negative views. The first of his positive suggestions for improving the tone of the professson is the introduction of a law enforcing at least one year's apprenticeship before the commencement of medical study; the second is the formation of a fund for the benefit of the profession, encouraging thrift among the active and giving help to the less fortunate. There is something to be said for both suggestions, but we confess to thinking them entirely inadequate as the sole levers by which the positive tone and power of the profession are to be raised.—*Lancet.*

THE SONG OF THE BACILLUS.

Once I flourished unmolested, now my troubles never cease;
Man, investigating monster, will not let me rest in peace.
I am taken from my kindred, from my newly wedded bride,
And exposed—it's really shameless—on a microscopic slide.
Sure some philbacillic person a society should start
For protection of bacilli from the doctor's baleful art.

Koch the evil game first stated, and his lymph came squirming in,
But, 'twixt you and me, bacilli did not care a single pin.
We went elsewhere in the body, and it only made us roam.
But it's hard, you must admit it, to be worried from your home;
And methinks the hapless patient had much rather we had rest,
When he finds us wildly rushing up and down his tortured breast.

Then came Bernheim and his dodges; his specific is to flood
All the circulation freely with injections of goat's blood.
That is really rather soothing, and it doesn't seem to hurt,
Though they lacerate your feelings with an automatic squirt;
Time will show if it's effective, but 'twill be revenge most sweet,
If the patients take to butting every single soul they meet.

Next fierce Liebriech, quite a savage, has declared that we shall die,
Shattered and exacerbated by the dreadful Spanish fly,
We should like to ask the patient if he thinks he'll live at ease
With his system impregnated with that vile cantharides?
We perchance may fall before it, waging an unequal strife,
But it's any odds the patient will be blistered out of life.

Therefore, O my friends, take heart, and these indignities endure,
Although every week brings news of an indubitable cure;
We have lived and flourished freely ever since the world began,
And our lineage is as ancient surely as is that of man;
While I'll venture the prediction, as a wind-up of my song,
That, despite these dreadful doctors, we may haply live as long.

—*From Punch.*

THE ODOR OF FLOWERS is controlled, as has lately been shown, by light and partially by air; excluding these agents flowers cease to exhale their perfume.

NEW BUILDINGS FOR THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA.

The Board of Trustees and the Faculty of the Jefferson Medical College have just completed the purchase of two large lots on Broad street, giving them a frontage of about 300 ft. and a depth of 150 ft., upon which they will proceed to erect at once a handsome hospital, lecture hall and laboratory building. The estimated cost of the building is $500,000. The hospital will be built not only as a suitable building in which to care for the sick and injured, but also will be provided with a large amphitheatre for clinical lectures. The basement of the hospital building will be given over to the various dispensaries, each of which will be provided with large waiting and physicians' rooms, as well as rooms for direct teaching for students. All the buildings will be absolutely fire proof and provided with patent sprinklers in case their contents catch fire. By the erection of three commodious buildings, the laboratories where delicate work with the microscope or apparatus is carried on, will be separated from the college hall where didactic lectures are given and so will be free from any jarring produced by the movement of large classes. With the hospital on one side affording clinical facilities, and the laboratory on the other side of the college hall for scientific research and training, the college will be most favorably situated for giving thorough instruction in medicine. Further than this, immediately across the street is the Howard Hospital, and on the adjoining corner the Ridgway branch of the Philadelphia Free Library, which contains all the scientific works belonging to this wealthy corporation. The new site is even more favorably situated in regard to the centre of the city than the old one at Tenth and Sansom streets. The move has been made necessary by the large number of students who are now being instructed in this institution, and because the Faculty desire to keep the school and hospital in the foremost rank of medical education in this country.

The buildings will be ready for occupancy in the session of 1893 and 1894.

DEATH BY HANGING.

The *St. Petersburger Medicinische Wochenschrift* gives a *résumé* of a paper by A. S. Ignatovski on the cause of death by hanging. He refers the rapid loss of consciousness after suspension to the retarded or arrested circulation in the brain brought about by the increased intra-cranial blood pressure. The

effect of this impediment to the circulation is the same as in cerebral anæmia, for in both the nutrition of the brain suffers. It is therefore, not as Leofman teaches, an insufficient supply of blood to the brain, due to compression of the carotids, which interferes with the functional activity of the brain, but compression of the capillaries by increase of the intra-cranial pressure, which has this effect, and which occurs whilst the supply of blood remains the same, or even increases.—*Lancet.*

PHYSICIANS IN CANADA.

Dr. R. W. Powell, of Ottawa, says (*Montreal Medical Journal*) that Canada has about 4,180 medical practitioners, arranged by provinces about as follows:

Ontario	2,300
Quebec	1,110
New Brunswick	170
Nova Scotia	300
Prince Edward Island	60
Manitoba	140
Northwest Territories	50
British Columbia	60
	4,180

TANNIN IN DIPHTHERIA.

Goyard has for several years followed this method of treatment in diphtheria with very satisfactory results (*Traitement Abortif au Croup et de la Diphtérié par le Tannin*, G. Carré, Paris, 1891). The treatment consists simply in the free application of tannin to the naso-pharynx. He uses for this purpose a round sponge, about half the size of an ordinary thimble, fastened to a piece of whalebone. Having first dipped the sponge in water and squeezed it between the fingers, he covers it with tannin by thrusting it into a box containing that substance, without weighing or measuring the dose. The patient being in the sitting position with his head a little raised, the tongue is held down with the left index, which is used as a guide for the sponge. The essential point, according to Goyard, is to get the sponge well beyond the isthmus faucium; after being kept for a second or two against the posterior wall of the pharynx it is withdrawn. When the disease is slight and in the incipient stage one application of this kind is said to be sufficient; in a case of croup or diphtheria following the ordinary course the tannin should be applied every two hours, the frequency of the local medication being reduced as the local and general symptoms of the disease subside. Goyard thinks the same method is indicated in all anginæ and laryngeal inflammations of miasmatic origin. The earlier the treatment is begun the more successful it is, and he urges the routine use of the tannin method in all cases of sore throat as a preventive of graver forms of disease.—*Brit. Med. Jour.*

PRESCRIBING OPTICIANS.

The law relating to the practice of medicine on the Continent is, as we know, administered with a far juster regard for the interests of all concerned than it is in this country, the reason of which is that it is not left to corporations and colleges to take action when rights are infringed and all illegal practice openly carried on. This is made manifest by a decision given by the law courts at Havre. An optician was successfully prosecuted for giving advice as to the condition of a patient's eyes, and who prescribed glasses to remedy the defect of vision. The court ruled it to be just as illegal to order spectacles as to order remedies or give medical advice without being a possessor of the diploma recognized by law. Prescribing and advertising opticians are becoming a nuisance in London, and will soon require to be looked after by the Medical Defence Union.—*Med. Press.*

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

CLINICAL LECTURE.

MYOSITIS.

By PROFESSOR H. LINDNER,

BERLIN, GERMANY.

Gentlemen: Primary inflammations of the muscles are very rare. Ample proof for this assertion is evident in the fact that every typical case yet reported has been found in the largest clinics or hospitals, where the material offered is most extensive; besides this, the cases reported have been but very few in number. The small number of cases reported might lead one to believe that this line of affections possessed but little practical importance; if we look closer, however, and examine the histories of individual cases we will find that in every case reported there were considered diagnostic difficulties. Apart from the surgical interest in these cases, there is another point interesting to pathologists, in reference to the pathogenesis and pathology of the disease, and this is that in the reported cases of myositis in the majority of instances it has been impossible to obtain any material for microscopical examination, and in those cases in which the possibility has been offered and the specimens obtained they have been subsequently lost.

The study of acute myositis is much more simple, since the reported cases—especially those collected by Von Scriba* and Walther†—clearly show that we are dealing with a localized infectious process. Although the material we have had at our disposal is yet very meagre, still it is most probable that in the near future our knowledge of the pathology and etiology of this affection will be considerably broadened.

A most peculiar and interesting case occurred in the practice of Dr. Reuter, and as I had an intimate knowledge of it—being called in consultation on several occasions—I will recite its history. In doing so I will quote from the notes of Dr. Reuter, which he has very kindly placed at my disposal.

The patient was a woman, 28 years old, who had been married for about three months. One day while walking in the street she experienced a sudden, sharp pain in the calf of the left leg. The parts became gradually more and more swollen, and when a month later the patient presented herself for examination the greater part of the gastrocnemius muscle was found to be invaded by a dense, hard infiltration. The swelling was not painful, and the patient was not confined either to her room or bed. There was no fever. Hot fomentations were applied, and subsequently at one point there was a slight softening. This point was opened, but nothing else than serum was evacuated. Soon after the opening was made, however, a profuse fetid discharge began—occasioned, undoubtedly, by the entrance of the atmospheric air. The wound became enlarged, and during the course of the following weeks, one could pull large pieces of necrosed muscle of a yellowish-gray color out of the wound. At the same time three or four abscesses opened spontaneously at different parts of the muscles, from which also large pieces of necrosed muscle were removed.

In the meanwhile the patient went about her daily duties as usual, feeling entirely well, and only coming to the hospital at intervals when the opening of a new abscess, or rather the pressure prior to its opening, gave her feelings of distress and some fever.

Six months after the first intimation of the disease, the necrotic process ceased entirely, and a month later the healing of the parts was complete. The patient has experienced no subsequent difficulties, and the limb which was affected is no weaker than the other, although its circumference at the calf is fully 2 c. m. ($\frac{3}{4}$ inch) less. There is no infiltration remaining in the muscle.

The treatment consisted primarily in the useless exhibition of iodide of potash for

**Deutsche Zeitschrift für Chirurgie*, xxiii, p. 497.

†*Ibid.*, xxv, p. 260.

three weeks. Subsequently, hot applications and poultices over the fluctuating parts until they opened, after which the wounds were dressed with creolin and rotterin.

The healing seemed to be hastened most decidedly by local bathing of the parts with sea-salt and water, and this treatment also seemed to facilitate the discharge of the gangrenous portions of muscle. The question, however, very naturally arises as to whether or not a similar bathing of the parts with plain water would not have accomplished equally good results.

The pieces of muscle taken from this case have been hardened in alcohol and subjected to a most careful examination. But I have only been able to find evidences of a muscular necrosis, with no infiltration or pus formation. In many of the fragments the muscular fibres have entirely disappeared, in others they may still be recognized by their contour, but their normal structure is entirely absent. The inner portion of the muscular fibres was entirely absent, and the fibres looked like hollow tubes, collapsed, tangled, and nicked. No bacteriological experiments were made at the time.

No other similar case to the above has as yet been published. The etiology would seem to point beyond all doubt to an infectious process, but to define this process is no easy task.

More difficult even than in the case of acute myositis, is the etiological definition of the chronic forms. This for the one reason that we are not always able to undertake surgical measures, and therefore are unable to obtain a view of the process as is the case in the acute form.

It seems—and I use the term "seems" advisedly—that there are two forms of chronic myositis: the parenchymatous and the interstitial. Pathological anatomists have left us entirely in the lurch regarding any data concerning chronic iodiopathic inflammations of the muscles, and all direct knowledge has been gleaned by traumatic processes.

When I said that there were two forms of chronic myositis, I should have added that I can furnish no anatomical proof for the existence of the parenchymatous form, since the only specimen I had in my possession has unfortunately been lost. Still, from the course of the case and the evidences gleaned from the specimen in question, I feel justified in having advanced the diagnosis of chronic, or more correctly subacute, parenchymatous myositis.

The patient was a poorly nourished young woman, who subsequently died of pulmonary tuberculosis, and whom I had been already treating for several months for abdominal troubles. The disease began by "tearing" pains in the right side, unaccompanied by any fever. Gradually a hard swelling appeared which occupied the entire iliac fossa. This swelling was painful upon pressure, and at certain points seemed to give evidence of a tense fluctuation. The accompanying stubborn constipation of the patient, and the region of the swelling, seemed to point to a probable disease of the cæcum and surrounding parts. So, I concluded to make an exploratory incision, and although I explored down to the sacrum, found no trace of pus, but only œdematous fluid. The muscles were remarkably hard, very pale, and waxy; the interstitiæ hardly recognizable, and apparently filled up by the swollen muscles. This condition rendered the exploration most difficult. Although the object of the operation was not accomplished, the disease subsequently disappeared within a few months. Probably this result was due to the release of pressure gained by the division of the fasciæ.

The finding in this case points to a process in the muscular fibres themselves. If the theory of an interstitial change were advanced in this case, then the narrowing of the spaces between the muscles could not be explained, for in such an event the spaces would be enlarged and the muscles easily divided. Cases, in which the muscles were similarly acutely and extensively diseased have been reported by Hepp. One of the cases died, and in the microscopical examination of the muscles, subsequently made by Recklinghausen, a parenchymatous inflammation and degeneration of the muscles was demonstrated.

Concerning the second form of chronic interstitial myositis, called "rheumatic" by Froriep, and *myositis fibrosa* by other authors, I am pleased to be able to show you, gentlemen, a most interesting case.

The patient is a woman, fifty-three years old, who came to this hospital* suffering from a most painful swelling of the leg from the knee down. Ten years ago she began to notice a gradually increasing weakness of the left lower extremity. The ankle-joint became swollen, and subsequently this swelling extended to the calf of the leg and nearly to the knee. The patient had complained of especially severe pains at night. These pains assumed the form of a severe burning sensa-

*Augusta Hospital, Berlin, Germany.

tion, the parts affected even feeling hot to the touch. Rest to the limb and cold applications afforded her considerable relief. The patient also says that the swelling and pain have both been greater or less at times. Until two years ago the patient, in spite of her pain, was able to walk without assistance, since then she has been bed-ridden for one year, and during this time the swelling of the leg materially increased in hardness. The patient claims previously always to have enjoyed the best of health. There are no evidences of syphilis and no specific history.

At present you see that the entire left leg from the knee to the ankle-joint is considerably larger than the right, and as hard as a board. It is impossible to distinguish muscle from bone, and it would therefore seem that the limb is surrounded by dense tumor originating from the bone. The skin is only slightly movable, infiltrated, and the veins enlarged. No part of the swelling seems especially painful to the touch, although the patient complains of most intense spontaneous pains. No soft or even points of a doughy consistency can be found; the position of the foot is normal. The temperature of the diseased limb is not different from that of the other.

My diagnosis wavered between a chronic inflammatory process and sarcoma. In order to confirm either diagnosis, I have not long since made several incisions—the patient being anæsthetized—and am positive of the correctness of my first surmise. All the muscles of the calf of the leg were transformed into a dense tissue, which crackled under the knife. The parts most extensively affected—the peronei muscles—were almost pure white, with a few scarcely visible, pale-red spots or strips; while the parts less affected—especially the gastrocnemius muscle—were covered more regularly with these red spots, while in the white substance of these muscles was a yellowish red, and plainly muscular substance visible at various points. Under the circumstances I concluded to refrain from any further surgical interference, and determined to try the effect of hot baths, etc., after the operative wound had healed.

The microscopical examination of portions of the peroneus muscle, which had been excised, showed these to consist almost entirely in tendinous connective tissue, in which isolated, atrophied muscular fibres could be distinguished. In the pieces of muscle excised from the gastrocnemius, bundles of muscular fibres were found, separated by broad divisions of loose connective tissue, which latter in many places is even found between the simple fibres. The fibres are considerably narrowed, the lateral stripe having disappeared, but a longitudinal stripe being very plain. The nuclei seem to be increased in number, although this apparent increase may possibly be due to the fact that the nuclei are brought closer together, giving an appearance of an increase of number.

Now, the woman's condition has not materially improved, and, indeed, an ultimate recovery from the local process is very questionable. The possibility of an ultimate recovery would be slim indeed were it to rest upon the necessity of the restoration to a normal condition of these muscles which have been strangulated by dense connective tissue, or in some instances even obliterated. Cicatricial connective tissue cannot well be regenerated into healthy muscle.

The local pains which the patient complains of so constantly, apart from the severe functional disturbances, no doubt have their origin in a strangulation or constriction of the nerves within the dense cicatrized or connective tissue.

Regarding the pathology of chronic myositis, in all the cases that have come to my notice the diagnosis has primarily wavered between myositis and sarcoma, and has only been confirmed after an exploratory incision had been made. Gies recently reported a case in which he had confirmed a diagnosis of chronic myositis at the end of the femur, by means of an exploratory incision.

It is furthermore an open question as to whether or not in the severer and more extensive forms of chronic myositis the same treatment as in severe cases of sarcoma would also be advisable—viz, amputation of the limb. The gain the patient enjoys by the retention of such a limb—as in the case before you—is entirely illusionary, especially when the constant pain and absolute uselessness of the limb is taken into consideration. And, indeed, the unnecessary postponement of such an operation might lead to a spreading of the disease.

In the case reported by Gies, and also in the one reported by Kreiss, recovery was obtained by the use of electricity and massage; and in light cases such a treatment is undoubtedly not without promise.

Regarding the prognosis, I have touched upon it sufficiently during the course of this lecture.

The etiology remains obscure, unless we would infer that rheumatism—that patient but victimized ailment which answers for so

many indefinable maladies—is its original cause. This theory is, however, of little weight, even when our limited pathological researches are taken into consideration.

PROLAPSUS UTERI, COMPLICATED BY SUPRA-VAGINAL ELONGATION OF THE CERVIX — ABDOMINAL SECTION FOR PUERPERAL SEPTICÆMIA.

By E. E. MONTGOMERY, M. D.

Professor of Obstetrics and Gynæcology at the Medico Chirurgical College—Obstetrician to the Philadelphia Hospital, and Gynæcologist to St. Joseph's Hospital.

Gentlemen:—The patient I propose to bring before you now is a woman thirty-eight years of age, whose occupation is housework; she was married at 16 years, and has given birth to four living and two dead children. Menses are regular, lasting three days and are accompanied with pain in the back and head, and with occasional inability to urinate. She suffers from profuse leucorrhœa, and this distress has been increased for the last two years. Bowels regular, appetite poor.

As we separate the limbs of the patient, you see there is a protrusion from the vulva; this protrusion is hard and dense. the finger can be passed in front of it, showing that it is not a cystocele, and in the same way posterior, which indicates that it cannot be a rectocele; we consequently must have then, a descent of the central portion of the vaginal canal or of the uterus. Prolapsus of the uterus varies in degrees: thus, where it has descended and is situated just within the vaginal orifice, it is known as first degree; where a portion protrudes through the vagina, it is prolapsus in the second degree, and where the entire uterus is protruded, it is known as the third degree or procidentia. In this patient the condition is one of incomplete prolapsus, as when a portion of the surface projects from the cavity and the finger can be passed anteriorly and posteriorly nearly the normal length of the vagina. In this condition consequently, with the fundus of the uterus situated high up, with the vaginal walls retaining their normal length and relations, we have to deal with a condition complicating prolapsus, and that is one in which the cervix has undergone elongation in its supra-vaginal portion, and consequently is known as supra-vaginal elongation, or hypertrophy of the cervix. This condition is one which is likely to take place where the perineal or pelvic floor has undergone disaster during parturition, and the uterus or vaginal walls are no longer supported.

The heavy anterior or posterior vaginal wall dragging upon the cervix will lead either to the displacement of the entire uterus, or in those conditions in which the fundus of the uterus is fixed by a healthy condition of its ligaments, or by inflammatory adhesions, the cervix itself is dragged upon, until, like any elastic tissue, it becomes elongated, in some cases forming a mere thread-like structure connecting the prolapsed portion with the fundus of the uterus above.

This patient, however, differs from the cases thus described, in the fact that there is no turning out of either the anterior or posterior vaginal walls; we have consequently an elongation of the cervix which has originated from the weight of the lower end of the cervix itself. If we come to investigate this, we find that the organ is quite dense and firm, enlarged, that it has undergone a bilateral laceration, and the ends of the cervix or lips are widely separated, giving it the appearance of the condition so aptly described by Goodell as a celery-top cervix. It is this organ, then, which has given rise to the elongation of the supra-vaginal, or intra-vaginal cervix. As I place my finger anteriorly and posteriorly to this, I find that the lower end of the cervix is quite large, spread out, while above it is very much contracted and cord like. The condition here has undoubtedly originated in the bilateral laceration of the cervix, which has taken place in some one of her labors, possibly an early one. The efforts on the part of Nature to restore the condition has led to induration, thickening and increased weight, and dragging upon the parts above, until this elongation has resulted.

In such a condition the patient necessarily complains of the sensation of dragging, weight and want of support, and in the upright position as if everything was about to fall out. There is also a great burning in the region of the cervix, and in the bladder. This burning, particularly of the cervix, is necessarily induced by the exposure of the delicate mucous membrane, and by friction of the sur-

---

* Clinical lecture delivered at the Medico-Chirurgical Hospital, Feb. 9, 1892.

face against the body of the patient, and against her clothing, with frequent bathing in the urine as it is voided. This, in some cases, leads to extensive ulceration. Bladder symptoms are not unfrequent in such states.

The traction upon the anterior vaginal wall leads to displacement of the bladder, which is closely associated with it, so that a portion of it is still below the internal orifice of the urethra, and is only emptied when the organ is pushed up. The retention of a portion of the urine in this way soon leads, by the increased amount of mucus secreted, to the disposition to inflammation of the mucous membrane, to burning and distress, to frequent micturition, and from this condition not unfrequently result calculi, sometimes of considerable size. It is a serious question in a patient suffering from a condition of this kind, as to what shall be done for her relief. How can the uterus be replaced and retained in its normal position? There are a number of mechanical appliances for the retention of a replaced uterus. We can readily understand that internal pessaries in such a patient would be of little value, for the reason that the cervix is so greatly elongated that it is likely to fall through the pessary, and if we should use the disc pessary, or one with a view of blocking up to a certain degree the outlet, and holding the cervix above it, the pressure upon the cicatricial tissue, and delicate cervical mucous membrane would result in abrasion, ulceration, and irritation so great as to render it unbearable, or would develop very rapidly a malignant disease.

Pessaries for external support are equally objectionable, so that we would dismiss the idea of attempting to maintain it by any such means. We are consequently left with the necessity of considering a surgical operation with a view to the correction of the abnormal condition. It is particularly important in this patient that the displacement should be relieved on account of the extensive laceration that exists in the cervix and the tendency there would necessarily be from its continued irritation to the development of malignant disease. The possibility of malignant disease arising in such conditions is no longer questioned; the fact that the disease in the uterus is often in the great majority of cases in the cervix, which is necessarily the site of any lesions following parturition, very strongly confirms the theories suggested as to the influence of this lesion in the development of malignant disease.

In this patient the condition is still more favorable to such degeneration, on account of the prolapsed state of the organ, its necessarily constant friction against the clothing of the patient or against her body, thus greatly increasing the irritation. What shall then be our course of treatment in such a patient? We may, very readily of course, overcome the dangers from the effect of the structure by repairing the cervix, freshening the edges and bringing the surface together by means of sutures. This would overcome the laceration of the surface, but often after it healed, we would have a very greatly elongated organ which would be prolapsed and give rise to a great deal of discomfort and inconvenience. So for this reason, in order to remove the irritation from its presence, I would suggest that an amputation of the cervix be made, pushing off the bladder from the anterior lip and dissecting up on the posterior lip nearly to the peritoneum, making flaps from the uterine mucous membrane, so that the formation of a non-contractile external os would be effected. This operation will remove the wedge-shaped surface from the vagina, which would greatly imperil any operation that might be done of a plastic character upon the vaginal walls, a condition which would sooner or later again develop the displacement of the uterus.

The first step, then, in the operation would be amputation of the cervix, and that high up. We will then retract the anterior wall of the vagina, which may be done by a variety of operative measures; thus, denuding a wedge-shaped surface, or a circular or oblong section, and affording opportunity to retract the vagina in different directions. In some cases the operation known as the circular denudation with purse string will be very effective. The retracted anterior wall must be supported by bringing the perineum up against it, which may be done by the Emmet operation, or in a case such as this, probably preferably by the operation recommended by Martin, which consists in taking out a section on either side of the posterior wall, bringing the edges of each denuded surface together by sutures, and then denuding and suturing the vulvar outlet. The difficulty in all operative procedures upon the vagina in these cases is the want of support of the upper third of the vagina. The result is, the uterus sags down upon the newly united surfaces, and acts as a wedge which favors still further the dilatation, and subsequently, after a length of time, makes its exit externally, leaving the patient in a more aggravated condition than before. This is particularly true of the denudation of the anterior wall of the vagina. If it does not unite readily, we have a push-

ing through the denudation of the bladder wall, covered with simply a thin layer of cicatricial tissue, which is so sensitive to pressure that it will not bear a pessary, and the condition of the patient is an exceedingly difficult one to subsequently relieve by any operative procedure.

If in this patient, we had, instead of the elongation of the cervix such as I show you, an entire prolapsus of the uterus, forming what is known as procidentia, with the uterus retroverted, in my judgment, the better plan of procedure would be to remove the entire organ, performing extirpation of the uterus when the vaginal walls might be closed, retracted laterally, and the tendency to prolapsus be very greatly lessened on account of the decreased weight at the upper portion of the canal. The operation would be an exceedingly easy one, as the vessels could be exposed and ligated without any danger of serious hæmorrhage. The plan of procedure, however, is not an applicable one to this case, for the reason that the fundus of the uterus is situated still high up. In a case of complete prolapse or procidentia of the uterus, in the Philadelphia Hospital some years ago, I performed what is known as the Le Fort operation, which consists in denuding a section upon the anterior wall about four-fifths of an inch in width the entire length of the wall, a similar one upon the posterior wall, and bringing these surfaces together by suturing the edges of the mucous membrane on either side in such a way that the raw snrfaces lie in apposition, forming consequently a septum dividing the vagina into two canals. The lower portion is strengthened by an operation on the perineum to narrow the vaginal outlet. This is a procedure which is extremely serviceable in those cases in which the climacteric is past and the woman is no longer in danger of becoming pregnant. It is, of course, as you would readily understand, an operation that might be attended with serious consequences in a woman during the child-bearing period, inasmuch as the existence of such a septum would necessarily greatly complicate delivery of the patient.

The patient upon whom I operated was seen two years afterward, when the uterus was found on the upper portion of the vagina, greatly atrophied, and the woman was able to resume her duties as a domestic without any inconvenience whatever. This patient I shall bring before you in a few days, if she is willing to consent to an operation, and will subject her to the operation we have just indicated.

PUERPERAL SEPTICÆMIA REQUIRING ABDOMINAL SECTION.

Three days ago, I operated upon a patient for a condition of so great interest that I feel that it would not be time lost to give you a history of the case and the plan of procedure. The woman was a patient of a gentleman engaged in a large practice in this city, and was delivered some four weeks ago of a still-born child which presented by the breech. The labor was quite difficult, was completed by instruments, and was followed in a few days by considerable elevation of temperature; the patient complained of pain over the abdomen, particularly in the right side, and there was not at any time any marked offensive odor. She was promptly placed upon vaginal irrigation and measures instituted to decrease the temperature. I saw her the sixth day after the delivery, when she had a temperature of 105.° We at once began the intra-uterine irrigation, and the use of salines, which resulted in decrease of temperature to nearly normal. This, however, within a few days again ascended, when she was placed under the influence of an anæsthetic and the cavity of the uterus carefully curetted with the finger, a large amount of débris and broken down membranes removed, the uterus irrigated with sublimate and afterwards peroxide of hydrogen, and then a rope of iodoform gauze carried to the fundus of the organ.

Her temperature the following day was below 100 and the second day, normal. The gauze was then withdrawn and intra-uterine irrigation again practised. Her temperature again began to increase, pain was more marked on the right side and we were finally driven by the indications of septic disease to the conclusion that it was necessary to resort to section of the abdomen with a view of removal of whatever might be the offending cause. We were inclined to believe that it would be the supra-vaginal removal of the uterus. In performing the operation, the patient was placed in the Trendelenburg position—that is, upon an inclining plane, the lower part of the body at an angle of forty-five degrees, so that the light from the window would fall directly into the pelvis. The abdomen was opened, and scarcely was the right wall lifted up until the discharge of the pus was observed. The intestines were hastily covered over with a cheese cloth towel, the pus sponged away, the opening effected and the abscess thus emptied.

Quite a large quantity of pus was removed from the abscess cavity, which was found to

consist of the right tube and ovary. These were enucleated, raised up, the pedicle ligated and their removal accomplished. In ligating the pedicle it tore off from the side of the uterus flush with it. As there was no pedicle, the bleeding from this was controlled by continuous catgut suture sewing the peritoneum over it. Bleeding was effectively controlled, the patient lowered, the cavity thoroughly irrigated and a drainage tube inserted.

Her temperature the following day ran up again to 103°, but under the influence of antipyretics it had fallen in the evening to nearly normal. Since that time her temperature has ranged from 95⅘° to 101°. Her condition in every respect is very greatly improved, and the chances for her recovery now seem to be quite favorable.

I recount this case as an illustration of what I have repeatedly told you in these lectures, of the importance of thoroughly clearing out the uterus early in septic cases to prevent the extension of inflammation to the tubes and ovaries, and in those cases in which there is indication of such extension, to use prompt measures to bring about the early removal of the secondary foci before the system of the patient is thoroughly poisoned.

COMMUNICATIONS.

A DISCUSSION ON PHAGOCYTOSIS AND IMMUNITY.*

At the Pathological Society of London, February 16th, 1892.

The President (Sir G. Murray Humphry) introduced the subject in a few words, in which he stated that the discussion was to show how the blood dealt with morbid material introduced into it. He then called upon Dr. Sims Woodhead, who delivered the following address:

II.—G SIMS WOODHEAD, M. D.
Director of the Research Laboratory of the Conjoint Board of the Royal College of Physicians and Surgeons.

Mr. President and Gentlemen:—I am sure we all have some little difficulty in approaching the questions that must be asked and satisfactorily answered before we can arrive at any definite conclusion as to the part that phagocytosis plays in the production of immunity against specific infective diseases. As in all great questions of this kind, the personality, energy, and ingenuity of the supporters of opposing theories have much to do with the temporary success of one or another system, though not with the ultimate result of any controversy. It is easy to prove anything to the credulous, but the proof of it to those who are neutral or who are absolutely incredulous is an entirely different matter, but certainly a much more satisfactory one; and I would here say there is no more satisfactory man to deal with than a friendly unbeliever. His objections stimulate our invention, and his candid criticism tests to the full not only our logical capacity but the soundness of our thesis. It is in that spirit of friendly unbelief, I hope, that we shall attack the arguments of those with whom we cannot agree; that we shall point out the errors of experiment, the faulty deductions, both direct and indirect, and that at the end of the discussion each one of us may carry away some additional facts, some new ideas, and the conviction that if some of our experiments are without flaw, others, interpreted in the light shed on the subject by other workers, may with advantage be repeated under various modified conditions and with the exclusion of any factors by which some of them at least may be rendered fallacious. It is impossible to discuss the relation of phagocytosis to immunity without introducing much concerning chemotaxis, and what has very aptly been spoken of as the humoral theory of immunity: the former of these is not antagonistic to, but may be actually looked upon as an essential part of, phagocytosis. The latter, however, is held as being in direct opposition to Metschnikoff's theory, though an attempt is now being made to combine the two; an attempt which, though up to the present unsuccessful, or, perhaps, one would say founded on little experimental basis, is gaining ground with those who, with the observations and deductions of the earlier investigators at their disposal, have taken up the matter. It would obviously be of no advantage that I should now attempt to make any suggestion even as to which theory—the "phagocyte" or the "humoral"—is supported by the bulk of evidence; though it will be gathered from the short summary here given of the work that has already been done that I lean to the theory of phagocytosis. Although Metschnikoff and Buchner may be looked upon as the present leaders in the two camps, a considerable amount of work preceded their scientific generalisms, and numerous observers are now engaged in testing the accuracy of their observations and deductions, and by improved methods are confirming or disproving the value of the earlier experiments.

From *Brit. Med. Jour.*

Taking first the question of phagocytosis from its physiological standpoint, and quite apart from its bearing on immunity, it has long been recognized that inert particles finding their way into the animal system, or even introduced into the blood immediately after it has been drawn from the body of the newt, say, are rapidly taken up by leucocytes, and, in the body, from them, by the connective or other fixed tissue cells. A similar process has been observed by every pathologist who has examined a healing wound, a section of the lung, or the cells of a normal spleen. The significance of this process was first pointed out by Haeckel, who, comparing the leucocyte of the newt with those of the lower amœboid organisms, indicated that this must be the remaining evidence of a normal process of nutrition common to amœboid cells in whatever position they may exist; these cells, taking the vermilion or carbon particles, merely affording a better demonstration of what is always going on in most amœboid cells.

Then came the observation that the vacuoles in leucocytes appear to be associated with the digestive and metabolic processes, partly as reservoirs for the accumulation of a digestive fluid, but more frequently for the accumulation of effete products.

ROSER'S EARLY OBSERVATION.

Attention was first drawn in 1881 to the part played by phagocytic cells in the production of immunity by Carl Roser, who, in an exceedingly interesting article, gave examples of the possession of this phagocytic power by the cell of both plants and animals, and of its importance in the resistance by them to the attack of the pathogenic fungi by which they are sometimes invaded. He maintained that the mobile amœboid cells of the animal body have the power of incepting, digesting, and assimilating even those living active micro-organisms which in non-resistant or non-immune animals have the power of withstanding the attacks of the devouring cells, and of continuing their existence and carrying on their specific functions in the tissues and fluids, where, as he found, they give rise to their characteristic products and set up the special manifestations of the disease with which they are associated; and he maintained that, as the result of his observations, he was convinced that this power of taking up such micro-organism must be an essential factor in the immunity enjoyed by non-susceptible animals. It was at this point that Metschnikoff—to whose patient researches, fertile and ingenious experiment, and brilliant powers of deduction we owe much of our knowledge of phagocytosis—took up the question, and, approaching it entirely from the experimental and biological sides, was able to build up, first, a theory of phagocytosis, and then of phagocytic immunity.

METSCHNIKOFF'S RESEARCHES.

He confirmed Haeckel's observations, and further demonstrated the fact that certain amœbæ and flagellated or ciliated unicellular organisms in the normal condition depend for much of their nourishment upon bacteria and fungi, which they destroy in large numbers, taking them into the substance of their protoplasm, extracting from them all nutritive substance, and then throwing out such matter as they cannot utilize. One of these small monads was observed to take into its substance within a few minutes filaments of leptothrix ten times its own length. This observation is one of prime importance, but one which we are apt to lose sight of in view of the apparently more interesting questions that have arisen in connection with the destruction of pathogenic organisms. Here we have unicellular animal organisms composed of imperfectly differentiated protoplasm, utilizing as nutritive material vegetable unicellular organisms, taking them into their substance and rejecting what they do not require.

It can scarcely be maintained for a moment that these leptothrix filaments are deprived of their vitality before they are incepted by the amœbæ, and we must therefore accept it as proved that these masses of elementary animal protoplasm can deal with living vegetable protoplasm as a nutritive material, the process of digestion going on within the cells, which do not act merely in self-defence in taking up these lower bacteria or fungi, but are actually dependent upon the process of ingestion and digestion for their nutrition.

It is not necessary here to multiply examples of this process, as Metschnikoff's elaborate researches on this point, quite apart from the many who have followed in his footsteps, place the matter beyond all doubt. Here then is the first fact—that these amœboid cells retain their activity and their functions, whilst the vegetable cells which they ingest are completely destroyed. Going a step further, Metschnikoff demonstrated that one of the layers of special differentiated cellular tissue met with in sponges, the mesoderm cells of which the animal is in great part composed, may still retain this power of ingesting foreign particles, each cell in this mesoderm layer playing the part of a

single amœboid protozoa, and he showed that they depend for their nutrition upon this intra-cellular digestion.

PHYSIOLOGICAL PHAGOCYTOSIS.

Phagocytosis in these cases, then, is not, as I have elsewhere stated, an isolated factor or a function brought into play for a solitary or rare occasion, but it is a habit upon which the animal cell depends for its very existence. This fact is more important when we bear in mind that any "fundamental" function of undifferentiated protoplasm is comparatively easily stimulated into activity when its presence is again required. It is a fact upon which the very foundation of the phagocytic theory depends.

Some time ago, whilst watching the development of the ova of the cod with Brook, of Edinburgh, the process of intra-cellular digestion was pointed out to me as occurring at certain stages in the whole of the cells of which the embryo is composed, small particles of yolk substance being taken into the actively proliferating cells and clear vesicles, which we can look upon as playing the excretory function, making their appearance. Later, however, where the cells are becoming differentiated, the intracellular digestion is confined almost entirely to the mesoderm cells; if we examine the parablast layer, the process of intracellular digestion is exceedingly well marked, the granules of yolk and the vacuoles standing out very prominently.

All will accept it as proved that in the metamorphoses of the tadpole, and of certain larval forms of insects, into fully developed forms, phagocytosis plays a most important part; but here it must be remembered that we are dealing with dead or partially devitalized tissues—tissues which have played their part, and are now to be looked upon as effete matter, and therefore not to be classed under the same heading as living active bacteria. Degenerating muscles, nerves, and fascia are devoured by active amœboid cells, and in this way the rapid removal of effete material is effected, an enormous number of phagocytes congregating to carry on the work at those points at which organs or parts are to be got rid of.

By a very natural extension, the part that this process of phagocytosis plays in the removal of dead or effete tissue after injury or disease has been also traced, the destruction of the myeline sheath of nerve fibres by amœboid cells, the absorption of bone by the large multi-nucleated cells that lie in Howship's foveolæ or lacunæ, the similar cells observed in myeloid sarcoma, especially in various tumors of the jaw, where absorption of the bone is going on rapidly, the inception of fragments of yellow elastic fibre and the absorption of muscle, not only in the tadpole's tail, as observed by Metschnikoff and others, but also in the inflammatory process set up by the trichina spiralis, as worked out so beautifully by Soudakewitch and in the involuting uterus by Helme, and others have all been followed out. Bevan Lewis has also shown that the connective tissue cells in the brain appear to exert a similar function in the removal of effete nerve structures, a most important point when considered along with the "associated fibres" and the part that they play in intellectual processes.

THE SOURCE OF MACROPHAGES AND MICROPHAGES.

Although in the first instance much stress was laid upon the leucocyte Metschnikoff, even in his earlier papers, and later Wyssokowicz, evidently had in view the fact that many of the cells were not true leucocytes, but that they were derived in some way or other from the fixed tissue cells, which appeared to undergo marked change under stimulation; they proliferate rapidly, they lose their specialized forms, their branching processes disappearing and the nucleus occupying a relatively large portion of the body of the cell; this nucleus as a rule remains single, but in all other respects these cells approach very nearly to the ordinary leucocyte, especially as they assume the specialized amœboid activity said to be so characteristic of the small cells. The single nucleated macrophages as distinguished from the small multi-nucleated microphages or leucocytes must indeed be looked upon as the final phagocytes, though, as we shall afterwards see they appear to have less marked powers of taking up living protoplasm than the leucocytes themselves, which in all essential respects approach much more nearly the primitive amœboid cells of the mesoderm cells of the sponge than do the large macrophages. The nearer the microphage under stimulation approaches the macrophage the more aggressive does it become and the less is it content to take up simply effete matter.

Even under normal conditions then these mesoderm cells, according to Metschnikoff, have as one of their functions the inception of all those solid parts of the organism that have became effete or useless, and where they are unable to carry out this function as individuals it would seem that they may combine in order to attack with greater certainty of success. As examples of this in the inverte-

brate kingdom, Metschnikoff points out that the mesoderm cell in the sponge may form a kind of network around bundles of leptothrix, gradually bringing about its destruction. In the same way it has been pointed out by Geddes that particles of organic or other matter, when introduced into the abdominal cavities of certain of the echinoderms, may, if small, be taken up by single cells, but where larger masses have to be dealt with a considerable number of such cells appear to run together, the protoplasm becoming fused into a large plasmodial mass, in which the individual nuclei of the original cells can scarcely be seen. Elsewhere I have indicated the part that myeloid or giant cells play in the absorption of bone and muscle and also in the parablasts of the ovum of certain fishes. In this latter case, however, the multinucleated cells, in place of being formed by single nucleated cells, running together, are the result of partial segmentation, the nuclei dividing but the protoplasm remaining as a single mass.

All this, however, has not led us beyond the point that amœboid cells in the higher animal organisms have the power, or rather the function, of removing innocuous material —organic or inorganic—or at any rate material that has, in the quantities in which it is usually present in the organism, no deleterious effects on the phacocyte cells. This is a perfectly different function from the phagocytic function that is exerted by the single-celled amœbæ or by the mesoderm cell of the lower invertebrate, which actually attack living organisms and depend on this power in a very large degree for their nutriment. We can readily understand how, in the process of development, where this attacking power is to a certain extent lost, as it is no longer necessary for the nutrition of the organism, the scavenging power may still remain in order to get rid in the most economical fashion possible of dead or inert foreign particles of chemical products and of effete materials of various kinds. Although this attacking power has in great measure been lost through disuse, it must still be remembered that it remains as one of the potential faculties of the primitive protoplasm, and that under suitable conditions it may again be brought into play; and, as Metschnikoff holds (and this is the key to his whole position), under certain conditions of stimulation the scavenging phagocytes may regain their original attacking function to such an extent that they may not only remove dead tissue and innocuous micro-organisms, but they may actually attack, ingest, and destroy micro-organisms to which, under ordinary circumstances, they would exhibit the greatest aversion, or, if these are brought into contact with them, to which they would succumb. We have here stimulation, but, as will be pointed out later, it is a special stimulation, and a stimulation that must be commenced gently and carried on for some time, increasing gradually, so that we may say there is a gradual preparation of acclimatization of the leucocytes before they can contend at all successfully with pathogenic micro-organisms, and before they can regain their phagocytic functions from the nutritive point of view, a function that may become so marked that the secondary or scavenging function is relegated to a comparatively unimportant condition.

TISSUE RESISTANCE AND TISSUE CELLS.

Tissue resistance, which may be translated as the power of reaction of cells, is necessarily intimately bound up with their life-history, with their powers of nutrition, with the facilities that they have for the excretion of effete matter, their power of taking up foreign bodies (such as pigment, bacteria, and the rest), and with their capacity for converting these into inert matter, and afterwards for utilizing them for their own purposes, and of getting rid of them. Even the physical surroundings of the cells, and, as we see, the reaction of certain chemicals on the protoplasm of the cells may interfere very greatly with some of these functions, and W. Pfeffer, in his careful observations on the action of aniline colors on vegetable cells, has pointed out what a great part the osmotic condition plays in inducing the absorption and retention not only of coloring matter held in solution, but also of solid particles brought in contact with the cells. He found, for instance, that on placing the cells of root hairs (and other vegetable cells easily examined) in a solution of 3 per cent. of saltpetre or of citric or malic acid, methylene blue, which under ordinary circumstances is taken up with great avidity by the protoplasm of these cells, is utterly rejected. The same appears to hold good in the case of solid particles. So far as one can make out from a careful study of the different results obtained by different experimenters, some such conditions as these have also played a part in determining the inception or rejection of living bacteria by the phagocytes.

It is not here necessary to repeat Metschnikoff's original experiment made on the water flea—the daphnia—with the monsopora dicuspidata—a form of single-celled yeast plant—but I would advise all who have not

read his interesting paper to make themselves thoroughly acquainted with the most fascinating account that he gives of the behavior of the needle-like spores of this parasitic yeast in the body cavity or in the tissues surrounding the intestine of its host. He shows how the small spore is taken up by the colorless blood corpuscles or by the connective-tissue corpuscles where the spore succumbs, and how it is developed into red-shaped vegetative form where these phagocytes, owing to weakness or number, are unable to deal with them. Upon this observation Metschnikoff's phagocytic theory of immunity was based, and it led to a series of the most ingenious and well thought out experiments that we have had since Pasteur's classical experiments in connection with fermentation and the production of disease.

I have pointed out elsewhere that erysipelas has been taken by the opponents of the theory of phagocytosis as an example which supports their contention that phagocytes play only a secondary part, and that entirely a scavenging part, in the process. They point out truly enough that the streptococci in erysipelas are outside the zone in which the leucocytes are collecting, and that there is little or no evidence of inflammatory reaction for some time after micro-organisms have made their appearance in the lymph spaces. They say, therefore, that if the cells in the inflammatory zone play any part at all it is only that of incepting the micro-organisms that have been destroyed by the fluid elements of the lymph or blood. But it may be here observed—to use a homely phrase—that what it "sauce for the goose ought to be sauce for the gander," and that we have no more evidence of destruction by the fluid elements in the spreading erysipelatous zone than we have of their destruction by the leucocytes; whilst we have evidence that as soon as the tissues are stimulated to react in the zone outside the proliferating micrococci, the conditions under which the cells can carry on their phagocytic functions become more favorable, with the result that the disease is localized. But of this I leave others who have worked at the subject to speak for themselves.

Let us see on what Metschnikoff depends for the proof of his theory of phagocytosis, and at the outset we may indicate that he draws a marked distinction between leucocytes and those cells derived from connective tissue—a distinction, however, which does not seem to hold good in all cases, as it is evident from what we know of the life-history of cells that extremely rapid proliferation of the connective tissue cells may take place under stimulation. Metschnikoff, indeed, indicated very early that many of the processes connected with the removal of the tadpole's tail were carried on by the larger fixed cells—a fact that was afterwards accentuated by Wyssokowitscky, and again by Helme in connection with the absorption of muscular fibre, by Metschnikoff himself, and by Soudakewitch. However, we will take the leucocytes as representing the phagocyte cells, and anthrax—a disease with which most work has been done—as the typical disease. In immune animals anthrax bacilli, which may be deeply stained with vesuvin or methyl blue, are invariably found within these cells, not only at the point of inoculation, but also in the blood. It has been stated that this coloring of the bacilli by aniline colors is no proof that the organisms were not killed before they were taken into the substance of the cell—a perfectly legitimate criticism, as we know that bacteria killed by heat, by chloride of mercury, or by absolute alcohol will readily take up the various staining reagents. It has been proved by Mitchell Prudden and Hodenpyl, that tubercle bacilli killed by being boiled for two hours and then injected into the circulation of an animal still take up aniline stains, and may often be seen as brilliantly stained rods lying in the tissue spaces, and in some cases actually within the cells, six weeks after injection.

THE ACTION OF PHAGOCYTES ON BACILLI.

This at first sight would appear an almost insuperable difficulty, but Metschnikoff overcame it by showing that bacilli in the leucocytes taken from immune animals still retain their power of vegetative reproduction by the following experiment. He placed some of these leucocytes containing bacilli on a warm stage under the microscope and by most delicate manipulative measures he was able to isolate three cells, each of them containing anthrax bacilli; each of these cells was taken up in a sterilized capillary tube, was then transferred to nutrient bouillon, and was watched under the microscope, the bacteria were seen to develop in length, and then when these were transferred to larger quantities of nutrient medium, a pure culture of the organism was obtained. Further, he has demonstrated that in immune animals the process of digestion goes on first in the leucocytes or microphages, but that afterwards not only microphages with their contents, but also other bacilli are taken up by macrophages, which appear to be derived rather from local fixed cells, though some of course may come from a distance.

Another proof that the micro-organisms are alive and probably active is found in the fact that although in most cells bacteria are undergoing degenerative changes they do not take on staining material at all readily, their protoplasm is becoming granular, or a great part of it has become absorbed, nuclei of the incepting cells still remaining distinct and deeply stained, vacuoles associated with rapid metabolic changes also being present; in some cases the cells are being actually broken down whilst many of the bacteria within them are as perfectly stained as are those taken from a young pure culture. This appears to be the case especially where a large number of bacteria are contained within each cell and where it would appear that the protoplasm of the cell has become exhausted through over-stimulation, and where in consequence the bacteria have gained the upper hand.

Frank, as the result of his experiments on white rats, in which he was able to obtain the death of one only out of twenty-two, although all the others had local anthrax lesions, maintained that the bacilli were killed *in situ* by the bacteria-killing serum which passed through the spaces in which the bacteria were confined. He says, however, that although they were localized first by the density of the tissues in this region, and secondly by an accumulation of leucocytes around them, in none of these leucocytes was he able to demonstrate the presence of anthrax bacilli. Metschnikoff, on the other hand, working under similar conditions, found that in the cells that accumulated in this part it was a comparatively easy matter by means of the use of special staining reagents, such as methylene blue, to determine the presence of bacteria in these cells, which he therefore holds are true phagocytes, and he further argues that Frank's experiments, in place of being contradictory, bear out his theory in a most remarkable manner.

CHEMOTAXIS.

It has for long been known that certain lower organisms exhibit a certain liking for certain substances, whilst for others they have an instinctive aversion, and from what has been observed it would appear that they are specially attracted to nutrient materials (trophotaxis). They maintain a marked indifference as regards substances from which there is nothing either to gain or to fear, whilst for other substances, most of which seem to exert some paralyzing or other deleterious effect on the cell, they evince the greatest dislike. Gabritchevsky, in summarizing this chemotactic action of leucocytes, gives a very good account of what has already been done (Adami gives a short abstract of this paper in the first part of his communication on immunity which appears in the *Manchester Medical Journal*). De Bary observes that in myxomycetes there were certain solid substances which, when brought near the plasmodium, exerted a vigorous repellent effect, the plasmodium in the first instance getting out of its way as rapidly as possible. If, however, these substances, with definite chemical characters, were introduced sufficiently gradually, the organisms would, after a time, become habituated to their presence, and would then actually take them up into their protoplasm. Metschnikoff, going out from his observations, had already conceived the idea that the acquired immunity against certain diseases might be due to a similar process of acclimatization of the cells, so that they are enabled to carry on their phagocytic functions in the presence of what, under ordinary conditions, would not allow them to come into sufficiently close contact to permit of their ingesting the microbes. This process of acclimatization can undoubtedly be brought about if the conditions be modified gradually and slowly, and it is now well known that cells, which at first would be quite unable to react in the presence of a specific poison, may ultimately be able to withstand large doses of it, and exert their special phagocytic function in its presence.

We have now numerous examples of the fact that if doses of poisons, produced by a specific bacillus, paralyze the amœboid cells, these same cells may by careful preparation, by the administration of repeated—at first small but gradually increasing—doses of the same poison, be so habituated to its presence that, after a time, the paralyzing effect is no longer excited, and the phagocytes are able to treat pathogenic organisms as comparatively inert foreign bodies, and the disease is kept under by the destruction of these organisms by the phagocytic cells. The organisms may remain in the body for some time, they may reproduce their poison, but the prepared cells are now able to carry on the scavenging functions even under these disadvantageous conditions, and in time the whole of the bacilli are taken into the cells, and, being unable to reproduce at any great rate, are gradually destroyed.

ANTIBIOTIC SUBSTANCES.

In marked opposition to Metschnikoff's phagocytosis theory, it was early brought

forward by Emmerich and Mattei that the property of destroying bacteria rested in the fluid constituents of the blood. They first maintained that these *antibiotic* fluid constituents were the result of the activity of the bacteria themselves; in fact, they took up the retention theory. After further observation, however, they receded from this position, and came to the conclusion that the *antibiotic* substances were formed by the living cellular elements. Following them, Flügge, Nuttall, and Nissen, who were afterwards joined by Buchner and others, described a bacteria-killing substance which was present in the blood of immune animals not only while it was circulating in the vessels, but also after it was withdrawn and had practically undergone coagulation, the serum being separated from the corpuscles—in which condition the blood might be said to have lost all traces of vitality. They hold, therefore, that a certain quantity of a toxic material, which apparently has little or nothing to do with the blood as a living tissue or fluid of the body, (in this differing from von Fódór's original idea, which was that there existed in the blood plasma a vital element which killed off the micro-organism). Following this up, Buchner maintains that the cause of recovery from an attack of an infective disease is directly due to a bacteria-killing action of the serum, and he further holds that phagocytosis is brought about merely by the dead microbes giving up their proteins, which, acting chemically in a positive manner, draw the leucocytes to the point at which the organisms are breaking down; here the leucocytes take them up and ultimately digest and get rid of them, so that he looks upon phagocytosis merely as the result, first, of chemotaxis and, secondly, of an effort on the part of the organism to get rid of the devitalized microbes. He admits that phagocytosis occurs only in those cases in which an effort is made on the part of the organism towards recovery, and that it is present only where an animal enjoys a certain immunity.

POSITIVE AND NEGATIVE CHEMOTAXIS.

Buchner holds that phagocytosis is entirely the result of positive chemotaxis, which in turn, so far as micro-organisms are concerned, can only be influenced by their proteids. The specific toxines can have little or no influence on the process. In support of this position he points out that Roux and Metschnikoff, both of whom believe thoroughly in the importance of the *rôle* played by the phagocytosis in the production of immunity, appear to hold different views as to the chemotactic action of these toxines on leucocytes—Roux indicating that they have a positive action; Metschnikoff, on the other hand, leaning to the opinion that they are negatively chemotactic, and that they repel the leucocytes. This, however, does not appear to be an insuperable difficulty, for we have ample evidence from numerous experiments that have been carried on that the same substances in different strengths of solution and under different conditions may exert very different chemotactic actions; and where one strength of solution may actually repel leucocytes, a more dilute solution may cause attraction. In this connection we shall probably have the pleasure of seeing some of Dr. Ruffer's specimens, in which may be well seen the effects of antiseptics, in different strengths, on leucocytes. I need not repeat to this Society Lister's classical experiments on the effect of heat on the movement of the cilia of a cell; but I may be allowed to notice that Schultz was able to show that the ferment power of yeast is distinctly increased by the addition of extremely dilute solutions of corrosive sublimate, arsenic, carbolic acid, and iodine, all of which in stronger solutions exert a very deleterious effect upon the protoplasm of the cells; he states his conclusion in the following words: "Every irritant exerts an action on every living cell in which the effect in relation to cell activity is inversely proportional to its intensity."

In order to overcome the objection of those who maintained that the organisms are killed by the fluids of the blood, and not by the cells, he took small boxes made of rose pith or of the pith of the common reed (phragmites communis), placed within them the spores of pathogenic organisms, and then introduced these into the veins, into the lymph sacs of the frog, or into little pockets under the skin of immune animals. The pith, for a time acting as a filter, kept out the cellular elements, and kept in the anthrax bacilli, but allowed free circulation of fluid through its interstices. He found that not only were the organisms not injured by the fluid, but they were actually enabled to vegetate and increase—in some cases very rapidly—in numbers.

Ruffer, who will probably give you the result of his own experiments, confirmed these observations, and pointed out further that the passage of generations of certain pathogenic organisms through the fluids of the body actually rendered them considerably more virulent—a result for which we had been prepared by Metschnikoff's experiments

on the increase of virulence of anthrax bacillus passed through pigeons.

BEHAVIOR OF LEUCOCYTES OF IMMUNE ANIMALS TO TOXINES.

Roux and Metschnikoff consider that leucocytes may become accustomed to the presence of considerable quantities of toxines in those cases where there is acquired immunity, and this appears to be undoubtedly the case in many diseases. In favor of the humoral theory, the single doubtful case of the vibrio Metschnikovi can be brought forward, for here it has been shown that even a guinea-pig immune to the subcutaneous injection of the organism still remains remarkably susceptible to the action of the toxines, though even here it is maintained that if the habituation be brought about extremely gradually, the immunity extends also to the poisons. In this case, it is supposed that we have stronger evidence of the correctness of the humoral theory than in any other disease, as it is maintained by Behring and Nissen that the serum from susceptible guinea-pigs affords a favorable medium to the growth of this organism, whilst that of immune animals kills them in five hours; but, on the other hand, Metschnikoff has pointed out that the vibrio Metschnikovi will grow in its normal form in the fluids of an immune animal, although when the same organism is cultivated in similar fluids removed from the body, involution forms are frequently met with. Here then we have a marked difference in the behavior of the organism in the living medium and in the dead. It is evident, in this case, that the fluids must have undergone some marked change on leaving the body, especially when we bear in mind that the organism remains alive for at least a fortnight when introduced into the anterior chamber of the eye of an immune guinea-pig. Roger made a similar observation as regards the streptococcus growing in the serum of immune rabbits, the organism growing freely but becoming attenuated. Roger and Charrin noted the same in connection with the bacillus pyocyaneus.

It must be borne in mind, however, that even Metschnikoff does not claim that phagocytosis is the only factor in the production of immunity. He claims merely that in immune animals it undoubtedly plays an important part, as here through the agency of the leucocytes and the proliferating connective tissue cells, living pathogenic bacteria are removed from the circulation; they are prevented from germinating, and thus the number of organisms is gradually diminished. He maintains, moreover, that it is by this process of phagocytosis that diseases are localized, and that from the very fact that we have a local reaction in immune animals we have an indication that the phagocytes are reacting to prevent the spread of the organism beyond the point of its introduction, and that thus we have, as it were, a first line of defence which must be passed before the disease can become generalized; and that in the endothelial cells of the spleen, of the blood vessels, and especially of the capillary blood vessels of organs in which there is very free capillary anastomosis and slow circulation, we have what may be called a second line of defence, and that when this is broken down the animal must succumb to a generalized disease.

In a short article on the recent researches on immunity, Adami suggests that there may be an increase in the bacteria-killing power of the blood plasma through the dissolution of a number of the white corpuscles. It is well-known that the breaking down of such corpuscles sets free materials which induce positive chemotaxis, and stimulates into greater phagocytic activity those cells which remain intact. In this case there appears to be some doubt as to the increased bactericidal power as the result of the setting free of the elements of the leucocytes. Working at this from one point of view, Wright has been able to demonstrate that anthrax bacilli may actually be cultivated on the broken-down leucocytes; further, it has frequently been demonstrated that quinine in large doses exerts a very marked action in destroying leucocytes in the animal body, and for that reason it was anticipated that to this action quinine owed the beneficial results obtained from its use in certain specific fevers.

Wood and I, trying this drug in cases of anthrax, found that in every case the animals treated with quinine died more rapidly than the controls—a most remarkable fact, and one which, along with the other observation, appears to negative Adami's suggestion as to the setting free of bactericidal material from dead leucocytes. Were it proved, however, we might, from our experiments make the very important deduction that the cells in a living condition exert a greater protective influence than they do when dead and broken-down, as even the control animal, in which the quinine has not been present to help to break down the leucocytes, lives longer than that in which the bactericidal power of the fluid is supposed to be increased by the diffusion into it of the elements of the broken down blood corpuscles. This is the more re-

markable when we find that almost all those who believe in the bactericidal power of blood serum assign to it a much greater efficacy after it is withdrawn from the body than when it is left circulating in the vessels. They assume that it has a much greater bactericidal power, so that this power must, to a certain extent, be inhibited within the body. Even here again we are met by a difficulty as a large proportion of leucocytes remain active after they are removed from the body; in fact the changes in them appear rather to be secondary to changes in the condition in the blood plasma.

Lubarsch believes with Flügge that the bacteria-destroying power of serum is exhausted by use, and that if the number of micro-organisms introduced is larger than that with which they can deal the animal must succumb. Metschnikoff, however, has been able, in certain partially immune animals, to demonstrate the presence of living bacteria four days after their first introduction. This would indicate that in cases which recover these organisms had, as it were, been waiting their turn to be killed off, the supply of poison not being equal to the demand, or on the other hand, we must assume that there is here a condition of almost perfect physiological equilibrium, those organisms that are not destroyed being just able to produce a few more than the next batch of poison can deal with, so that, unless some other element comes in, such as increased production of poison or the calling in of the phagocytes to help in the work of destruction, the production of bacteria might go on indefinitely.

IMMUNITY PRODUCED BY VARYING PROCESSES.

One of the great mistakes that has been made, and is still made by many, is that it is assumed that immunity against different diseases may be obtained or acquired in the same way. It is evident that the processes by which immunity can be obtained must vary as widely as do the processes of disease themselves. As Lubarsch points out, tetanus and diphtheria are as different from anthrax as possible. The primary mechanism of the diseases are absolutely unlike, while the same may be said as regards typhoid and tuberculosis. Tetanus and diphtheria must be looked upon as toxæmias or septicæmias, using this term in the sense in which it was used some few years ago. The organisms which produce the poison are strictly localized to a very definite area around the point of introduction, but they form poisonous substances which, taken into the circulation, give rise to marked disturbances and degenerations, especially of the highly organized tissues, such as the nerves, muscles, and excreting epithelium. One can understand what an injurious effect such poisonous material must have on the tissue cells, and even on the leucocytes, at the point where the poison is introduced, especially if these poisons are introduced at once in a virulent form; the cells are paralyzed, they are at once attacked by the organisms, and form a nutrient substratum on which they can grow. If, however, the cells can be habituated to the presence of small doses of poison it is quite conceivable that eventually we might produce an immunity, from the fact that we had acclimatized the animal to larger doses of the poison than it could secrete when introduced; and that, therefore, the cells would be able to carry on their destructive functions, and thus get rid of the organisms before they could do any harm. As a matter of fact, it has been shown that the tetanus organism, unless accompanied by a considerable quantity of its specific poison, is absolutely unable to flourish in the healthy tissues, so that in this case, at any rate, the immunity has to be acquired against the action of a poison formed by the bacillus, and diffused into the body, rather than against the growth of the bacillus itself.

The same holds good to a certain extent in the case of diphtheria, the conditions necessary for infection by this organism appearing to be either (1) inflammations of the mucous membrane, accumulation of secretions, formation of ulcers and similar conditions, or (2) the introduction of a considerable mass of the organism, accompanied by a quantity of the specific poison. In both cases it is probable that we may actually find that in the process of rendering the animal immune we may actually set up the degenerative changes so characteristic of diphtheria.

It is probable that similar changes may be found in animals that have been protected against tetanus. Probably some of those taking part in this discussion Dr. Sidney Martin, Dr. Hunter, and others, will have something to say on this point. In the case of anthrax it is necessary to produce an immunity which (1) will localize the disease at the point of introduction, or (2) which will enable the tissues to act on the organism at once, probably in the first case through the leucocytes, for we can scarcely imagine that a sufficient quantity of the fluid elements of the blood can be brought up to attack a large number of organisms when the blood of the whole body, according to Lubarsch, can determine the destruction of only 10,000

anthrax bacilli. Even a very high degree of alteration in its bactericidal power would scarcely enable it to deal with the large numbers that may be introduced locally. Only some such factor as the bringing up of large numbers of leucocytes, which, owing to a natural or acquired immunity, are enabled to act in the presence of anthrax poison, can bring about, first a localization of the anthrax bacilli by the erection of a cellular barrier, and secondly, their destruction by a process of ingestion and digestion.

In all our researches on immunity we are confronted with the question, How is it that immunity is conferred for one disease only, or certainly for one series only? Why should an attack of vaccinia or variola be necessary to ensure protection against another attack of variola? The exhaustion of assimilation theory was early found insufficient to account for it, as it was also to explain the different action of the bacillus prodigiosus, which, whilst diminishing the action of a dose of anthrax, increases the virulence of Chauveau's bacillus or charbon symptomatique. The local immunity theory in the same way was found insufficient, and local inflammation as a factor in immunity has also had its day, perhaps, however, to be revived at no distant date. The adaptation theory or cellular chemical theory advocated by Klebs and Grawitz, Ribbert's theory of massing of leucocytes, and Metschnikoff's phagocyte theory have in turn ousted the retention theory advocated by Wernich and Chauveau, whilst the serum bactericidal theory has come forward to rout this if possible. It may be that we may have to cull something from each of several of these various hypotheses, but we must always bear in mind that the potential forms and functions of animal protoplasm are as great as the number of directions in which it actually develops. Its property of resistance to any special poison, or its power of carrying on its functions in the presence of such poison, can always be brought about by exercise. It falls into abeyance again, no doubt, when not required, but once revived it is far more readily again brought into play when again called upon. Each poison it is held develops or recalls a special resistance, and it is in the rapid development of this special resistance that immunity consists.

Even should the bactericidal power of serum be proved to exist, it must depend directly upon changes produced in the cells, changes which must be equally specific if what we think we know about immunity is at all to be trusted. Immunity is specific, whilst this bactericidal power of serum is very general in its action unless we accept it that the blood must be loaded with a fresh bacteria-killing material for every disease we contract from childhood upwards, beginning with whooping-cough and measles, and passing through the whole gamut of the ills that flesh is heir to.

II.—J. BURDON SANDERSON, M. D., D. C. L., LL. D., F. R. S.

Waynflete Professor of Physiology in the University of Oxford.

Dr. Burdon Sanderson stated very briefly the general grounds for not accepting the doctrine of phagocytosis. The specific power enjoyed by the organism of protecting itself against the exciting causes of specific diseases was, he said, admitted by all pathologists. It was also admitted that the intervention of leucocytes is associated in many instances with the successful exercise of this power by the organism. In these instances the action of leucocytes is recognized as beneficial, but many pathologists decline to vest in them protective power or to recognize any direct relation between their activity and the specific exciting causes of specific diseases; and attribute the phenomena of phagocytosis to the ordinary endowments which leucocytes manifest, not merely in disease, but under normal physiological conditions, such for example, as those under which they act in the processes by which effete structures are absorbed. Unless it can be shown that this is not the case, there is no reason for assuming the existence of those special endowments by which, according to the theory of phagocytosis, they are enabled to act independently of the organism for its protection.

III.—E. KLEIN, M. D., F.R.S.,

Lecturer on General Anatomy, etc., St. Bartholomew's Hospital.

Dr. Klein admitted his inability to accept the argument advanced by the supporters of the phagocyte theory, and in support of his position he stated that the question of phagocytosis embraced a very much wider field of observation that was included in the views already advanced. Some investigators included all instances in which bacteria were found engulfed in cells. This, he contended, was the first error, and illustrated his remark by exhibiting a number of photomicrographs showing a dozen instances of micro-organisms contained in cells which were breaking down under their influence, thus reversing the process described. He

said, that the influence of chemotaxis, as shown in the cells of bileducts in which psorosperms were growing, was of quite a different nature to that asserted, In the many cases of immunity in which inoculation was not followed by disease, were the bacilli killed by leucocytes, by some other agent, or by the two in combination? He referred to the experiment of Emmerick and Mattei in which it was shown that the micrococcus of swine erysipelas which would kill a rabbit when injected subcutaneously, did not do so when introduced into the circulation, and further, that an animal so treated acquired immunity from infection by some subsequent inoculation, and that phagocytes cannot then be found at its site. Reference was made also to the observation of Metschnikoff that after forty-eight hours living bacilli can still be found in the blood of an immune animal; but it was stated that in such cases there was not a commensurate number of cells containing the micro-organisms. In the dog, cat, and rat, which were insusceptible, it was extremely difficult to find any adequate number of baccillus-bearing cells after inoculation. In the next place, he would ask if there were any well-established cases in which bacilli were known to have been destroyed by lymph or other juices; and here he alluded to experiments being carried out by Dr. Fred. Andrewes, and which showed that pus, already dead, and even when twenty-four hours out of the body, had a rapidly noxious effect upon these organisms. When anthrax was introduced into the dorsal lymph sac of a frog, it was hours before any bacilli were seen inclosed in cells, the lymph itself being capable of destroying them.

Professor Klein then gave an account of some experiments in which it was found that a rapid diminution in bacilli occurred within two hours of introduction into the body, which was not at all in accord with the time observed in their gradual approach and engulfment by cells. He thought it was much simpler to assume that the juices of the body were germicidal, though Buchner's explanation gave little account of what took place with regard to the bacilli after they were weakened by exposure to them, as to whether they were then taken up and carried away by cells acting as scavengers. That important part of the cell's duty had yet to be proved.

IV.—A. A. KANTHACK, F. R. C. S.,

John Lucas Walker Student in Pathology, Cambridge University.

Taking phagocytosis in connection with immunity to mean the ingestion and destruction of living micro-organisms by certain wandering or fixed cells of the body, I assume that, at the present date, no doubt exists as to the occurrence of such a phenomenon. Phagocytosis is almost consistently observed in cases where an animal recovers after being inoculated with a pathogenic germ, or where an animal, artificially or naturally immune, is inoculated in the same manner. It has been claimed that phagocytosis is the chief, if not the only, factor in the acquisition of immunity.

I would abstain from alluding to the origin and nature of the phagocytes, were it not that Dr. Ruffer—as far as I can follow him—asserts that all phagocytes, including microphages and macrophages, plasmic and epithelioid cells, are derived from leucocytes. On the contrary, there can be no doubt that the plasmic and epithelioid cells, observed during inflammation and regeneration, are derived from the fixed connective tissue cells *in situ*. This has been shown by the researches of Grawitz, Ziegler, Nikiforoff, Bardenheuer, and also by Messrs. Ballance and Sherrington. Personally, I have on several occasions repeated the experiments of Grawitz and Bardenheuer, and cannot accept Dr. Ruffer's views.

The question at issue is "whether immunity from infective diseases or lesions is caused by phagocytosis, that is, through the phagocytes alone, and through nothing else." Though phagocytosis may be constantly observed in immune animals, it may for all that be simply a concomitant physiological effect or change due to the acquired immunity.

I shall only discuss acquired immunity, for it is evident that the only logical method to study the process of acquiring immunity is by means of considering the changes in the organism while passing from a non-resistant to a resistant state. Personally, I think that at the present state of our knowledge, we cannot accept any one theory as exclusive, but though acknowledging that phagocytosis is of great importance as a protective mechanism, I am unwilling to accept the exclusive phagocytic theory, believing that the acquisition of immunity rests on a much broader basis than the voraciousness of the leucocyte.

I shall discuss only three chief points, as it is impossible to allude to all the various matters in the short time alloted to me. These points are: I. The Influence of the Body Fluids; II. Chemotaxis; III. Phagocytosis.

I. Do the living fluids of the body play no part in the production of immunity?

The serum of many animals has a marked bactericidal power outside the body, but we cannot establish any general law, because there is no necessary correlation between the natural insusceptibility of an animal to a disease and bactericidal power of its serum over the microbe causing such disease. This has been put forward as a grave objection to the so-called humoral theory. But I think wrongly, for it is to my mind impossible to draw any logical inference as to the artificial causation of immunity by contrasting a naturally immune animal with a naturally susceptible one. In future, experiments should be made in such a manner that the bactericidal power of the serum of a naturally susceptible animal be tested (*a*) before it has been immunized, and (*b*) after it has been artificially immunized.

If, then, any law can be established, we must expect to find one or more of three conditions—namely, after the acquisition of immunity, the serum should be:

(1) either more bactericidal,

(2) or possess greater attenuating powers,

(3) or possess greater destructive power over the toxines of the microbes.

It is too narrow to judge by the bactericidal power alone, for it is impossible to disconnect the bacteria from their metabolic products, and it is these which cause the disease. As long as the poison is not neutralized it matters not whether the bacilli are eventually killed or not.

To give examples, we find—

(1) Under the first head that

(*a*) the serum of the guinea-pig after immunization kills the vibrio Metschnikovi;

(*b*) the serum of a guinea-pig after immunization has greater bactericidal power over the Chauveau bacillus.

As an exception, we may mention the serum of a sheep protected against anthrax. But, on the other hand, Christmas succeeded in extracting from the organs of an immunized rabbit a substance which had greater destructive power over the anthrax bacillus than a substance similarly extracted from the organs of a rabbit not protected against anthrax.

According to Bouchard, it has been proven for nine infective processes that the serum of the immunized animal has greater bactericidal power than the serum of the same animal in the non-immunized condition. These are anthrax, charbon symptomatique, cholera, erysipelas, diphtheria, tetanus, pneumonia, and the lesions caused by the vibrio Metschnikovi and the bacillus pyocyaneus.

(2) Under the second heading, we find that

(*a*) the serum of the immunized rabbit attenuates the streptococcus of erysipelas;

(*b*) the serum of the immunized rabbit attenuates the bacillus pyocyaneus.

(3) Finally, under the third heading, we find that

(*a*) the serum of an immunized animal neutralizes the tetanus toxine;

(*b* and *c*) the same has been asserted with regard to the toxines of diphtheria and pneumonia.

Experiments in this direction and on these lines should be extended.

Now it is true that an experiment in a test tube with *post-mortem* or dead serum we cannot immediately apply to the changes and action of the living fluids. But we must not be too dogmatic, and say "because the serum of the naturally susceptible guinea-pig is more destructive to Chauveau's bacillus than the serum of the naturally less susceptible rabbit; *ergo*, test-tube experiments prove nothing." Such an experiment is not crucial.

Some test-tube experiments are almost conclusive. I am alluding to the action on tetanus toxine of blood freshly removed from an immunized animal. Anyhow, we may claim that test-tube experiments logically conducted are suggestive, for the serum is in the first instance derived from the plasma, and if we find constant changes in one or other direction after artificial immunization, it is reasonable to suspect changes of similar nature in the plasma and body fluids also. With Bouchard we cannot possibly consider this almost constant increased bactericidal power over a particular microbe after immunization against such microbe a mere test-tube accident.

I can only allude to some of the many objections offered. These should always be examined in the light of logical evidence, and if derived from experiments on animals of two absolutely different species, of which one happens to be naturally susceptible and the other naturally refractory, they may be rejected at once.

(1) Those who object to test-tube experiments as being artificial do not hesitate to use little paper bags filled with germs, and place them under the skin of refractory or immunized animals. Such experiments are as little natural as test-tube researches, for (*a*) we thus localize the process by artificial means; (*b*) the fluid which passes through the paper may be of an inflammatory nature, and is not necessarily the same as the normal body fluids. For this reason I have not alluded to Sanarelli's experiments, who showed

by using collodion tubes that the lymph of frogs *in corpore* can attenuate, or even kill, anthrax bacilli without the aid of phagocytes.

(2) Waiving this objection for argument's sake, Dr. Ruffer claims to have disproved the protective influence of the living plasma by his latest experiments. He placed the vaccine of charbon symptomatique wrapped up in paper under the skin of an immunized rabbit, and found that even after forty-eight hours, the vaccine will certainly kill guinea-pigs. This, to my mind, proves nothing, for it is not at all necessary that the plasma or body fluids of the immunized rabbit should kill or attenuate the bacillus; the animal will survive as long as the poison is destroyed, and the immunization of the rabbit may simply have enabled the organic fluids to do this. The fact that the exudation was able to wash away a part of the metabolic products of the bacilli secluded in the paper can only be of advantage to the growth of the same.

It may be mentioned in passing that, claiming such powers for the organic living fluids as I have done, does by no means imply a retrogression to the ancient humoral pathology; for no one, I take it, denies that all our fluids are the products of cellular secretion or excretion, and this is all that cellular pathology demands.

In studying the artificial production of immunity, the absolute followers of Metschnikoff are prone to neglect the most important part of the causation of infective diseases and lesions, namely, the chemical products of the microbes which undoubtedly cause the phenomena of such diseases.

(*a*) We find that an animal made immune against a living microbe can also resist the toxine of such microbe to varying degrees. Examples are tetanus, pneumonia, diphtheria, vibrio Metschnikovi, pyocyaneus, charbon symptomatique, and others.

(*b*) *Vice versâ*, an animal made immune against the toxine also resists the living microbe. Therefore the processes responsible for these results must assumedly be the same. Now immunity against toxines cannot in any way whatever be explained by means of phagocytosis.

I conclude, therefore, that at the present state of knowledge it is impossible to assert that the living plasma (or body fluids) are of no consequence. I will not claim more for the present.

II. *Chemotaxis* has been of late introduced as a welcome support of the phagocytic theory. Certain chemical substances, according to their degree of concentration, attract or repel the phagocytes, but if the phagocytes are in a medium already containing these chemical substances, equally distributed, they will not be attracted on adding more of these substances, unless they be added in a highly-concentrated condition. Analyzing this, we have three possible cases:—

(*a*) The metabolic products of the microbe are present in equal quantity in the tissues and at the seat of lesion, therefore no migration of phagocytes can take place.

(*b*) If the degree of concentration is higher at the seat of lesion, we shall have a migration of phagocytes thereto.

(*c*) If the degree of concentration is higher in the blood, the phagocytes may migrate back into the blood.

This teaches us nothing as to the acquisition of immunity, for (1) if true, it is simply a statement of concomitant facts; (2) on such a view, our successes in the production of immunity become merely a matter of chance and good fortune; (3) it supposes, without the slightest foundation, that in an animal immunized against a microbe, the toxine of such microbe circulates in its vessels; and, lastly, it neglects the fact that besides diapedesis, we have, as a rule, hand in hand with positive chemotaxis, a great general increase of phagocytes and leucocytes, depending of necessity on a stimulation not of the luecocytes and phagocytes but of the elements giving birth to these bodies. Hertwig in his monograph sums up this theory in the following manner; "(*a*) In an immunized organism, the negative chemotaxis, which the body exhibited before being made immune, has been replaced by a chemotaxis behaving positively towards the specific virus." If so, we may ask why and how? We are also told that "effects of the metabolic products of microbes show themselves as positive and negative chemotropism and also as acquired irritability (Reiznackwirkung). The existence of positive chemotropism explains the localization of the virus through the attraction of leucocytes and subsequent phagocytosis. The existence of negative chemotropism explains the possibility of a general infection by means of a diffusion of the micro-organisms. By means of suitable injections of bacillary products a negative may be changed into a positive chemotaxis, and thus a cure be effected." This is mystical and unsatisfactory, and treats of the body as though it were a specimen on the microscopic slide.

III. We now come to the last point, *phagocytosis*. I repeat that I fully acknowledge that this exists, and also that it is an impor-

tant phenomenon during and after the acquisition of immunity, but I am far from accepting that it is the sole, or even the chief, factor active in all cases alike. The exclusive phagocytic theory is both inadequate and unsatisfactory. I will not repeat the classical objections which are always answered by the same classical arguments, but shall enumerate a few difficulties as they have presented themselves to me.

(1) By causing fever artificially in a susceptible animal; two or three hours after the temperature has began to rise considerably there is a very great increase of leucocytes, not only of the so-called lymphocytes but also of the larger elements, and this leucocytosis persists for more than twelve hours. On inoculating the animal when in this condition with anthrax, it will die just as usual. Yet here the army of phagocytes was increased at least tenfold.

(2) Thus the increased number of phagocytes *per se* is not sufficient. They require also the special training. And here we come to the most unsatisfactory part of the theory. Before the animal is immunized the phagocytes are more or less inert against a particular microbe, but as soon as ever a relative immunity is established they are extremely voracious. We must ask, why does phagocytosis appear now or why are the cells suddenly enabled to destroy what previously perhaps killed them? Metschnikoff says by means of a kind of special selection or change of habit. This to my mind amounts to saying that the cells themselves have acquired immunity; and phagocytosis instead of explaining the processes by which immunity is acquired, becomes simply a phenomenon observed during or after the process. We must also remember that in many cases after the protective inoculation we have to wait from four to sixteen days before immunity is apparent, and during this time the natural resistance may even be decreased, as Fränkel's experiments on diphtherial immunity show. Leucocytes and wandering cells are but short-lived, and as far as we know constantly replaced through continuous division of cells which form the elements of certain tissues and organs. Thus the assumed hereditary resistance must be sought at the birth-place of these leucocytes and wandering cells. If we allow so much, we might as well say the phagocytes are immune because the whole body has become immune, or simultaneously with the immunization of the organism, phagocytosis appears.

(3) The occurrence and importance of vaccine fever during the process of immunization points to more general changes than a mere change of habit of the phagocyte alone.

(4) That changes exist in all the tissues has been shown by Emmerich, who succeeded in protecting animals by inoculating them with the tissue juices of immunized animals.

(5) Some of the methods of immunization, as the injection of the so-called antitoxine, or of small repeated doses of poison, etc., point strongly to general changes in the body, the phagocytes being altered with the rest of the body.

(6) Lastly, phagocytosis does by no means explain many of the phenomena mentioned in the first part of these remarks. Other objections might be raised, but I am afraid I have been using up time too much already.

In conclusion, it seems to me that we cannot hold any one process exclusively responsible for the artificial production of immunity. The primary cause of immunity, however, must be sought beyond the leucocyte or phagocyte, and also beyond the fluids of the body and, according to the maxims of cellular pathology, depend on changes in the cell-life of the organism which at the present we are unable to understand. It is in consequence of these as yet obscure molecular changes that phagocytosis and the other phenomena observed after or during immunization appear, but none of these alone can be considered the cause of immunity.

[TO BE CONTINUED.]

PEROXIDE OF HYDROGEN.

The following formulæ are from Dr. B. W. Richardson's Asclepiad:

For Fermentative Dyspepsia:

℞
S lut. hydrogenii peroxidi (10 vols.).....ʒ iiss.
Spiritus vini rectificati.....ʒ iij
Ol. creasoti.....ℳ vj.
Glycerini puri.....ʒ vj.
Aquæ destillatæ.....ad ʒ vj.
Misce. Fiat mistura. Dose, f ʒ j.

For Hæmoptysis and Other Hæmorrhages:

℞
Solut. hydr genii peroxidi (10 vols.).....ʒ iiss.
Tannin.....ʒ ss.
Glycerini puri.....ʒ vj.
Aquæ destillatæ.....ad ʒ vj.
Misce. Fiat mistura. Dose, f ʒ j.

An Antidote and Astringent Gargle.

℞
Tannin (pure).....gr. x.
Glycerine (pure .....ʒ j.
Rectified spirit.....f ʒ iv.
Distilled water.....f ʒ iv.
Solution of peroxide f hydrogen (10 vols.) sufficient for 8 fluidounces. To make an 8-ounce gargle, to be used in the manner directed.

A Useful Collyrium.

℞
Solution of peroxide of hydrogen (10 vols.)..ʒ iv
Tannin (pure).....gr. v.
Rose-water.....to f ʒ viij.
To make an 8-ounce collyrium, to be used in the manner directed.

REMOVAL OF SARCOMA OF MESENTERY AND RESECTION OF A PORTION OF SMALL INTESTINE.

By DR. JAS. McCANN,
SURGEON TO THE WEST PENN HOSPITAL.

Reported by Dr. E. E. Wible, Resident Physician.

Thomas W., a German, æt. 40, was admitted to the general surgical ward of the West Penn. Hospital on Nov. 30th, 1891. He was a married man, and was employed in a rope and cordage factory. He entered the hospital for the treatment of a tumor which he had discovered in his abdomen. His family history was negative, with the exception that his mother and an aunt had died of dropsy. As to his personal history, he said that he had had inflammation of the lungs and rheumatism some years ago. Last September, pain in his abdomen attracted his attention to a hard movable tumor of about twice the size of a normal kidney. This tumor occupied usually the right inguinal region, but it could easily be manipulated to any position in the abdominal cavity.

The existence of this tumor had not been previously suspected by the patient, who states that he has had no gastro-intestinal disturbance, but was troubled some with constipation. His general health is excellent, and he does not seek treatment on account of any pain or physical debility, but the knowledge of the presence of the growth worries him and causes him to be uneasy.

The tumor is hard and smooth, spherical in shape, and it seems at times to change its position with the peristaltic movements of the intestines.

A diagnosis of a morbid growth was made, and it was differentiated from a floating kidney by reason of the absence of any urinary trouble and its free mobility.

Dr. McCann decided to perform laparotomy for the removal of the tumor, which was accordingly done at his surgical clinic before the students of the Western Pennsylvania Medical College, on Dec. 1st, 1891. After opening the abdomen he exposed at once a tumor adherent to the mesentery and a loop of the small intestine. The tumor was partly dissected away, when it became apparent that it would be necessary to resect about eight inches of the bowels on account of the tumor being so closely adherent to it, and incorporated with the wall of the intestine. Gibson's clamps were applied to the fixed portion of the intestine to prevent fæcal extravasation during the operation of enterectomy. The bowel was then severed by scissors and a "v" shaped portion of the mesentery, corresponding with the portion of the bowel, was also removed.

The cut edges of the mesentery were then coaptated by continuous sutures after the hæmorrhage had been arrested. The open ends of the divided intestine were then united by two rows of fine silk sutures; one uniting the mucous surface with continuous sutures; the other uniting the muscular and serous coats with continuous Lembert's sutures. The incision through the abdominal wall was then closed with silver-wire sutures and a rubber drainage tube was inserted, which was removed on the second day. The operation was performed with strict attention in every detail to antiseptic precautions. The tumor weighed a few ounces short of two pounds. The microscopical examination disclosed that it was a spindle-shaped sarcoma. The patient received nothing but sips of hot water during the first forty-eight hours following the operation; he was then allowed a meagre liquid diet for the ensuing two weeks, and he then gradually returned to the use of solid food. No opiates were administered because he did not have any pain. His pulse and respiration never exceeded the normal. His highest temperature was on the evening of the seventh day when it registered 101.4°; it then gradually returned to the normal in four days and remained so henceforth. On the sixth day he had two natural evacuations from the bowels and every day succeeding had one or two evacuations.

In order that he could enjoy the association of his family on Christmas day he departed from the hospital in perfect health on Dec. 21st, 1891, just twenty-one days after the operation.

Three months after the operation the patient reports that he is at his accustomed employment every day and that he never enjoyed better health in his life.

PYOKTANIN IN OPHTHALMIC PRACTICE

As a result of the employment of pyoktanin for a period of three months in the ophthalmic service of Bacchi, Rescoussie (*Annales de la Policlin. de Paris*, 1891, No. 12, p. 549) concludes that the agent is an excellent antiseptic in ocular surgery—to be preferred to all others. It exercises a favorable influence upon simple conjunctivitis, and especially upon granular conjunctivitis. It is of doubtful efficacy in case of rebellious ulceration of the cornea, and is almost useless in case of purulent ophthalmia.

A CASE OF ACUTE PARENCHYMATOUS NEPHRITIS.

By MARTIN W. BARR, M.D.,
Brookline, Mass.

The treatment of acute parenchymatous nephritis is a series of compromises all through the whole course of the disease, and each drug given cannot be too carefully watched. So much has been written on the subject—on purely theoretical grounds—that frequently when a case of this dreadful disease comes under the care of a busy general practitioner he is bewildered by the variety of remedies presented. I have endeavored to describe this case most accurately, going into all the minute details of both symptoms and treatment.

S. T.,—aged thirty years. An unmarried gentleman of unexceptionable habits. Native of England. Had been in America about ten months. Was engaged in intellectual work for a number of years. Family history good. Patient had not been feeling well for several weeks. Complained of headache. Was irritable and listless. Sleep was disturbed at night, would doze much during the day. Appetite failed.

On May 3, 1891, complained of sore throat. On examination I found the throat much congested.

Prescribed:

℞ Fld. ext. rhus. glab.
Glycerine.....āā ʒi
Sat. sol. potass. chlor..... ʒij
M. Sig. Gargle every half hour.

Used gargle during day, and in the evening throat was improved. Took a walk and half-an-hour's smoke after night-fall. Retired early.

May 4th—Was dull and heavy and slept much during the day. Took but little food. In the evening had a slight chill. Became dizzy and staggered when walking. Complained of double vision. Conjunctiva much congested. Tongue was heavily coated. Gave hydrarg. chlor. mitis, gr. iii., and later, sod. brom., gr. l.

May 5th—Passed rather a restless night. Was very nervous and exhibited signs of mental disturbance. Had severe cephalalgia and aching pains in shoulders and lumbar regions. Voided urine in large quantities, but with great difficulty. The desire to micturate was almost constant, and the flow strongly resembled that in polyuria. The urine was colorless, and contained neither albumen nor sugar. Specific gravity was 1006.

Polydipsia was a marked symptom, the craving for cold drinks being most intense. This continued until convalescence.

Kept patient in bed and gave:

℞ Potass. iodidi.....gr. clx
Syr. sarsap. comp.....ʒss.
Aquæ.....ʒiss.
M. Sig. Teaspoonful in water every our hours.

Also:

℞ Fld. ext. hyoscyamus.....grs. xl.
Sodæ bicarb.....grs. xxxii.
Aquæ, q. s.,.....ad ʒi.
M. Sig. Teaspoonful in water every two hours.

In addition I used the galvanic battery, applying the electrodes alternately along the spine, and to the hypogastric, lumbar, and inguinal regions; and also to the root of the penis. I began with moderate currents, but rapidly increased them in strength. Gave milk freely.

May 6th—Patient pessed a bad night. Muscular twitchings of face and limbs. For hours I momentarily expected a convulsion. Uræmic symptoms were very prominent. There was but a faint odor to the urine—breath and perspiration were strongly urinous. Cephalalgia was less severe. Vertigo very marked. Conjunctiva was a bright yellow and blood-vessels strongly injected. Disordered vision—diplopia. A *bruit* was distinctly audible in cardiac region. No fever. Pulse slow and full. Respiration during day was shallow and irregular (Cheyne-Stokes); toward evening labored. There was some delirium which was mild and muttering. Tongue still furred. Teeth covered with sordes.

Ordered tinct. digitalis, m. v., *ter in die*. In the evening gave hydrarg. chlor. mitis., gr. v., followed by a Seidlitz powder.

May 7th.—Patient passed another wretched night. Diplopia more marked. Everything appeared a bright green color. Delirium increased. Would lie muttering to himself, then suddenly have attacks of wild maniacal excitement. Had illusions and hallucinations. Thought that he had had a quarrel on the quay with some negro roughs, by whom he had been injured. Afterwards a strange man had given him a cigar and told him to go lie down in his (the man's) room. This story was repeated over and over. He held conversations with an imaginary man, clad in blue trousers, sitting on a stile. Was much interested in some black trees. Attended his own funeral. Had a severe disagreement with his brother. Was much afraid of a box, which he thought had been placed high up in a window by his head. Became violently angry with me, and, later, imagined that I was the devil. Toward evening became more quiet but insisted that he was not in his own chamber. Bowels moved freely. Urine passed in large quanti-

ties and with great difficulty. Continued treatment, and at bedtime gave: sod. brom. ʒj., and morph. sulph., gr. ¼.

May 8th.—Passed a restless night. Arose frequently to urinate. Was extremely weak and dull. Wild delirium had subsided, and given place to listless apathy. Patient lay during morning in a lethargic state, from which he could be easily roused to take nourishment and medicine. Toward noon he began to wander again. Spoke of a choir singing; held a conversation with a little child of whom he was very fond; then began to talk of suicide. Gave podophyllum gr. ¼ every hour, until three doses were taken. Bowels were freely moved late in the afternoon. Fell asleep early in the evening, waking occasionally. Recognized me. Strong urinous odor to breath and perspiration. Gave chloral gr. x, and morph. sulph. gr. ¼ at bedtime. I now placed patient on an absolute milk diet, feeding him at regular intervals. He would take seven pints in twenty-four hours. My schedule ran thus:—

8 a. m.	1	pint.
10.30 a. m.	1	"
12 m.	1	"
3 p. m.	1	"
6 p. m.	1	"
10 p. m.	1	"
During night when awake	1	"

May 9th.—No change of any importance. Hebetude of mind still continued. Heart irritable and irregular in its movements. Patient had no idea of time. Had completely lost it. Morph. sulph. gr. ½ at bedtime.

May 10th.—Slept rather better during night. Mind was wandering. Was aphonic, speech unintelligible at times. While left alone for a few minutes, escaped down two long flights of steps, and engaged in an altercation with a man whom he met. Was returned to bed much exhausted. Passed urine with less difficulty, and in smaller quantity. Bowels freely moved by hydrag. chlor. mitis. gr. iii, and podophyllum gr. ½. Stopped hyoscyamus mixture, also digitalis.

May 11th.—Much disturbed by having room changed. Toward evening became drowsy.

May 12th—Patient passed a quiet night. Abnormal flow of urine had ceased. He had an almost constant desire to urinate, but could pass only a few drops at a time. Urine of a dark red color, and was loaded with urates. Bowels freely moved, spontaneously.

May 13th.—Urinous odor to breath not so marked. But little odor to the urine. Patient was still very dull.

May 14th.—Micturition not so frequent, and only a small quantity voided at a time.

May 15th—Urinous odor rapidly disappearing from breath. Urine was a pale straw-color, neutral reaction, specific gravity 1010, and contained neither albumen nor sugar. Small cloudy sediment on standing-water. Microscopic examination revealed some pale hyaline casts. Polydipsia was still most intense. Slept much during day. In the evening had an attack of maniacal excitement which came on without warning. Had the delusion of a quarrel. Was quieted with difficulty. In the morning I gave podophyllum gr. ⅔, followed in half an hour by a Seidlitz powder. Full movement resulted. Stopped all other medicine and prescribed:

℞
Tinct. digitalis ..... ℥ lxxx.
Potass. acetat. ..... ʒ vsi.
Aquæ q. s. ad ..... ʒ viii.
M. Sig.—Teaspoonful well diluted every 4 hours.

This I gave between meals. Directly before each meal the patient took tinct. ferri chlor. m. x., together with Mensmen's beef tonic, ʒ jss. Immediately following the meal he took liq. potass arsenit. m. ii., in wineglassful of water. At bedtime gave morph. sulph. gr. ¼ and sod. brom. ʒi.

May 16th.—Had rather a quiet night. Mind was much lighter, although he had no idea of time. Talked coherently. Aphasia disappearing. Diplopia in less degree. Dipsomania unabated. Allowed him to get up for a few minutes. Was extremely weak. Some diarrhœa in afternoon. Promptly checked it by fl. ext. geranium maculatum, and tinct. opii m. x. to iv., every hour until took four doses.

May 17th.—Improving; delusions disappearing. Eyes clearing up, congestion less intense, yellow color fading. One healthy voluntary stool. Allowed him to smoke a little morning and evening. He also took two short walks. Much exhausted afterwards.

May 18th—Gave usual sleeping potion on previous night. Slept through the night and until 11 a. m. Is much improved in every way. Began to take solid food. Steak, eggs, custard, bread and butter, etc. Took two walks. Was not so tired after them.

May 19th.—Mind quite clear. Urine voided in normal quantities, and with no difficulty. Appetite good. Took much exercise during day. Was extremely tired at night. Gave sleeping draught.

May 20th.—Diplopia disappearing rapidly. Dipsomania is not nearly so intense. Urinous odor hardly perceptible on breath.

May 21st.—Took a twenty-six mile ride on the cars, and did much running around in the

city. The day was very warm, and in the evening patient was much exhausted. No movement from bowels.

May 22d.—Slept soundly during the night. Eyes yellow and slightly congested. Urinous odor to breath exaggerated. At 2 p. m. gave pulv. jalapæ comp. gr. xiv. Free evacuation in the evening.

May 23d.—Restless night. Urine light colored. Specific gravity, 1020. Taking nourishment freely. Good movement from bowels. On this day the patient was removed from my personal care, although I continued to prescribe for him at a distance. I followed the treatment last mentioned for a number of days, and the patient improved rapidly. About June 1st I changed treatment, and put him on the chloride of gold and sodium. The prescription read:—

℞ Auri et sodii chlorid. .....gr. iii.
Aquæ.....ʒ iv.
M.
Sig.—Teaspoonful in water after each meal.

When patient had finished this, I reduced dose to gr. , *ter in die.*

No inconvenience in any form was experienced from the continued use of this drug.

By the middle of July discontinued all treatment. Saw patient on August 7th. Looked well and strong. A microscopic examination of the urine was made on October 5th; a number of granular casts could be plainly seen.

At the present time of writing the patient is in splendid mental and physical condition. I have warned him of the great care he will have to take of himself.

The most curious symptom in this case was the vast quantity of urine passed in the beginning. So large was the amount that I at first thought the disease was diabetes insipidus. Usually in acute parenchymatous nephritis the flow is diminished, or suppressed entirely.

The delirium is also worthy of special notice. It was that of enteric fever, but there were no other typhoid symptoms. One thing I should *not* recommend in the treatment of acute Bright's disease—the allowing the patient to smoke. My patient was determined to smoke, and no amount of persuasion nor arguing on my part could prevent him. When I found that he was rapidly working himself into a state of mental excitement, I quietly submitted. Fortunately, no bad results followed, but it is an experiment I should not care to try again. It will perhaps be noticed that I never allowed my patient to lower his vital forces, but kept the fuel burning brightly by the forced feeding—milk and beef tonic.

A HAWTHORN TWIG IN A MAN'S EAR FOR THIRTY YEARS.

By A. O. STIMPSON, M.D., C.M.,
Thompson, Pa.

John Nickels, aged 74 years, came from Parkham, England, to this country some eighteen years ago, and gives the following history of himself:

"In the month of January, 1844, while forcing his way through a dense hawthorn hedge the end of a hawthorn twig entered his ear and broke off, causing him considerable pain at the time. After he had returned home it had bled quite freely, but on examination nothing could be discovered in the ear. In the course of time, however, he became quite deaf, the ear commenced to pain him considerably, attended more or less with a purulent and fetid discharge. Shortly previous to this, he had been to several reputable surgeons and submitted to a thorough examination, but they claimed that no foreign object could be found in the labyrinth of the organ. When the amount of discharge from the ear became diminished in quantity the pain and discomfort became sensibly aggravated, and gradually the sense of hearing on that side became seriously impaired. His wife says that at times he has acted as if he were partially insane, and she noticed that he felt worse when the discharge became diminished in quantity. The pain has continued to be very severe at times, especially after any extra amount of labor or exertion in his daily occupation as a farmer and agriculturist, and, as he describes it, 'crackling sounds were heard in his head.'"

With the exception of this infirmity and the resulting semi-deafness, his general health has been very good. On Monday, the 16th day of January, 1879, he came to my office and requested me to examine his ear and see if nothing could be done for his relief, claiming all the while that he felt as if there were something in his ear. After introducing a silver bivalve speculum in his ear, with the aid of a strong artificial light I discovered a dark hard-looking substance projecting through the internal meatus. With a pair of long narrow-bladed forceps I succeeded in getting hold of the object, and by careful manipulation finally extracted it. There was very little bleeding attending the operation, but a profuse discharge of very offensive purulent matter. The substance extracted was the budded end of a twig a half inch in diameter and one and a half inches long by actual measurement, which was somewhat

flattened on two sides. It consisted of tough, hard, woody fibre with the adherent bark. Mr. Nickels took the substance home with him and unfortunately lost it, so that afterwards I could not obtain it to exhibit as a specimen. He persistently claimed that the substance entered the right ear, while it certainly was extracted from the left ear. I am confident, however, that he certainly must be mistaken in regard to it as the broken end of the twig presented first. It seems almost incredible that this broken piece of a hawthorn twig could have remained in this man's head for over thirty years without giving rise to more serious symptoms; but both his wife and himself at the time persistently attest to the truth of the aforesaid statement.

After the operation he was advised to syringe out the ear with the following lotion, to be used warm:

℞ Acid carbolic, (officinal strength).....gtts xxv
Glycerine,.....℥ j
Aquæ ferveus,.....℥ iv.

His wife stated (a month after the operation) that he had not since complained of severe pain in his head, and that there has been but very little discharge. His hearing, however, has not materially improved, but he certainly has very much gained in general health, and he has not been annoyed with ringing noises in his head as formerly. After the extraction of the twig by the aid of the speculum I could plainly see the drum of the ear had been perforated, hence there was no possibility of his sense of hearing ever becoming improved.

ENDOCARDITIS FOLLOWING CIRCUMCISION.

Czerny (*Prager med. Wochenschr.*, No. 39, 1891) has reported the case of a child of Israelitish parents, that was without antiseptic precautions circumcised on the fourteenth day after birth, and two weeks later presented restlessness, apparent difficulty of breathing, elevation of temperature, and loss of weight. On osculation over the body of the heart systolic and diastolic murmurs were heard, but the organ was not enlarged. The diastolic murmur subsequently disappeared and cardiac hypertrophy developed. Prior to the operation the heart had been auscultated, and no murmurs were heard; so that etiological association between the operation and the endocarditis was quite clear.

Strychnine is used as an antidote for snake bite in Australia.

SELECTED FORMULÆ.

THIOL IN CONSTIPATION.

The following formula has been found useful (*Pharm. Centralb.*) in constipation:

℞ Thiol.....gramme 0.10.
Micæ panis.....q. s. ut ft. massa.
Ft. pil. no. x.
Sig. One pill daily.

—*La Médecine Moderne*, Suppl., November 5, 1891, p. 170.

CREOLIN-IODOFORM OINTMENT.

Creolin.....m. xx.
Iodoform.....gr. xl.
Vaseline.....℥ i.
S. Make an ointment.

The odor of iodoform is completely masked. —*Nouveaux Remèdes.*

INFLUENZA.

Prof. Bacelli, of Rome (*Le Bulletin médical*, No. 4, 1892), praises the following formula in the grippe:

℞ Phenacetine.
Salicylate of quinine, } .....āā cgms. 10.
Camphor,
Kermes mineral, ...āā mgms. 3.

Sufficient for one powder. Three or four such powders a day.

PIPERIDZINE.

Piperidzine (*Lo Sperimentale*, No. 21, 1891), the great uric acid solvent, is prescribed as follows:

℞ Piperidzin. pur..... .....gr mme 1.
Aq. destillat.....grammes 180.
Syrup corticis aurant..... " 20.

Sufficient for twenty-four hours. The dose may be gradually increased to three grammes (forty-five grains) per day.

For hypodermatic use inject as follows:

℞ Piperidzin. pur.....decigrammes 3–5.
Aq. destillat.....grammes 10.

Inject a Pravaz syringeful every two days. After fourteen days the dose may be increased to ten centigrammes

ACUTE BRONCHITIS.

℞ Vini ipecacuanhæ.....℥ ij.
Liq. potassii cit.....℥ iv.
Tinct. opii camphorat.,
Syrup. acaciæ.....āā ℥ j.

M. Sig. A teaspoonful, thrice daily, in the first stage of ordinary bronchitis.

HICCOUGH.

Dr. Whelpley recommends the following:

Subnitrate of bismuth.....grains 45.
Oxide of zinc..... " 60.
Valerianate of zinc..... " 60.
Powdered calumba..... " 60.
Powdered opium..... " 1½.
Spirit of anise to flavor.

M. The dose is half a teaspoonful in a wine glass of sweetened water.

EARACHE.

An earache cure, recommended by a German medical journal, is made as follows:

℞ Chlorinated camphor.....pints 5.
Glycerin..... " 30.
Oil of sweet almond..... " 10.
Mlx and moisten cotton, and place in the ear.

—*Cincinnati Medical News.*

CREOLIN-IODOFORM OINTMENT.

The advantage of this prescription (*Les Nouveaux Remèdes*) is said to be that the smell of the iodoform is well masked.—*Therap. Gazette.*

Creolin.....grains 15.
Iodoform..... " 30.
Vaseline.....drachms 6.
Make into an ointment.

OINTMENT FOR ERYSIPELAS.

Corrosive sublimate .....gr. ss.
Lanolne.....5 v.
Vaseline.....gr. ss.

—*Med. Press and Circular.*

PROPHYLAXIS AND TREATMENT OF MERCURIAL STOMATITIS.

Dr. Feibes (*La Semaine médicale*, No. 57, 1891) regards dentifrice powders and gargles as the best means of preventing mercurial stomatitis during a "course" of mercury. He uses the following powder as a dentifrice:

℞ Cretæ preparat.....grammes 32.
Potass. chlorat.,
Corticis cinchonæ rubræ.....āā " 16.
Ratanhiæ..... " 10.
Sapon. medical..... " 23.
Essent. menth. piperit..... " 3.

As a gargle he employs:

Alumin. acetat.....grammes 10.
Aq. destillat.,
Aq. flor. aurantior.....āā " 200.

If the gums become sensitive they may be sponged three times a day with:

℞ Tinct. myrrhæ,
Tinct. nuc. gall.,
Tinct. ratanhiæ.....āā grammes 5.

CHILBLAINS.

The following is recommended:

℞ Ol. terebinth.,
Balsam copaiba.....āā ʒ i.
S. Apply to surface when not denuded.

—*Notes on New Remedies.*

DISINFECTANT INTRA-UTERINE INJECTION.

Dr. Ter-Grigoriantz (*La Semaine médicale*, No. 59, 1891) praises the following:

℞ Sublimat. corrosiv.....cgms. 10.
Acid carbolic.....gms. 20.
Acid boric..... " 40.
Acid salicylic..... " 5.
Zinci chlorid..... " 10.
Aq. destillat..... " 2000.

DERMATOL.

In the clinic of Dr. von Rogner, at the Wieden Hospital, Vienna, dermatol has been found efficacious in the treatment of wounds, burns and abscesses. It was used:

1. Pure, as dusting-powder.
2. As ointment:

℞ Dermatoli.....ʒ v.
Vaselin. flav.....ʒ xx.
M. Sig. Ungt.

3. In collodion emulsion:

℞ Dermatoli.....ʒ iij.
Collod.....ʒ iij.
M. Sig. Use locally.

INFLUENZA COLDS.

"Few remedies are more reliable, and act better as a preventive, or lessen the distressing symptoms of an influenza cold, than the following mixture:

℞ Sodii salicylas.....ʒ jss.
Liq. ammon. acet.....ʒ ij.
Aq. camph.....ad ʒ vj.
Misce. Capt., ʒ ss. omnis 3tiis horis.

If this be taken every two or three hours when the first symptoms of cold come on, it will usually ward off the attack."—*British and Colonial Druggist.*

BENZOL IN INFLUENZA.

Robertson (*British Medical Journal*, No. 1621, p. 171) recommends the employment of benzol in the treatment of influenza—and he has likewise found it useful in the treatment of whooping-cough. The symptoms of the disease are speedily and favorably influenced, and pneumonia seems to be prevented. Benzol can be dispensed in capsules or in mixture, in doses of three minims for children and five minims for adults, every two or three hours. The following formula may be employed:

℞ Benzol. pur.....ℳ lxxx.
Spts. vini rect.....f ʒ ss.
Spts. chloroformi.....f ʒ iij.
Mucilag. tragacanth.....ad f ʒ viij.
M. Sig. A dessertspoonful or a tablespoonful at a dose, to be taken in lemonade.

MIXTURE FOR HÆMORRHAGE.

℞ Powdered ergot.....drachms 2½.
Sulphuric acid.....minims 30.
Distilled water.....pint 1.
Boil and evaporate to six ounces and then add
Alcohol.....drachms 6.
Syrup of cinnamon.....ounce 1.

—*Pharmaceutische Post*, No. 27, 1891.

GONORRHŒA.

The following (*Lo Sperimentale*, No. 18, 1891) is spoken highly of in gonorrhœa:

℞ Ergotin.....dgms. 3.
Aq. destillat.....gms. 300.
Inject twice a day.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO. (Incorporated)
PROPRIETOR AND PUBLISHER.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.)

CHARLES K. MOUNT, Advertising Manager.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates),..... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts,.....$1.50 each.
Bovine Points or Quills,..... 1.00 a doz.
Humanized Crusts,..... 1.00 small.
Humanized Crusts,..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

LEADING ARTICLE.

IODOFORM GAUZE TAMPON IN POST-PARTUM HÆMORRHAGE.

The method of packing the uterus with strips of iodoform gauze for post-partum hæmorrhage, occurring either from atony of or injury to the womb, was originally advanced by Dührssen. Although the previous experiences with the method have been most satisfactory, still objections are very frequently raised: the tampon may in many cases be superfluous, it might easily lead to an infection, and it hinders the contraction of the womb, all of which would seem designed to increase the possibility of hæmorrhage rather than lessen it.

These opposing statements have led Dr. Stæheli, of the Obstetrical and Gynæcological Clinic of Berne, Switzerland, to report his extended experiences with the method. This report first appeared in a recent number of the *Correspondenzblatt für Schweizer Aerzte*, but has also been editorially discussed by the *Medicinische Neuigkeiten*, and elsewhere.

That the method has an indisputable value is evident from the fact that out of 5,424 births occuring at the above named institute since 1880, there have only been nine deaths from hæmorrhage occurring shortly after child-birth.

Out of forty-nine cases in which the tampon was used, a passing elevation of temperature was observed in five cases, and death in one case, owing to sepsis subsequent to Cæsarean section. These results as opposing the objection of possible infection are most favorable in support of the procedure, especially as it must be remembered that the tampon was used in the most severe cases, where frequent manual examinations had not only been undertaken, but where operative procedures had not infrequently been resorted to.

Regarding the third objection raised, viz. that a tampon in the utero-vaginal canal is likely to do more harm than good, the simple fact that in all of the forty-nine cases all hæmorrhage from the genitalia was rapidly

and permanently checked, entirely sets aside this objection. In no case was any hæmorrhage observable after a removal of the tampon, and only a few insignificant clots were ever formed in the meshes of the gauze. These results were obtained in hæmorrhages resulting from atony of the uterus, which had withstood every other available therapeutic means, and also in cases of injury where a suture could not be made, either from the fact that the bleeding point could not be rendered visible, or else because the undertaking of such an operation in the face of so copious a hæmorrhage was out of the question.

Since the adoption of Dührssen's iodoform tampon in obstetrical therapeutics the course of a birth complicated by post-partum hæmorrhage may be described as follows:

A diagnosis as to the source of the hæmorrhage is of primary importance, whether it be from the utero-placental wound, or from a laceration of the vulva, vagina or uterus. The hand of the operator, placed over the uterus from without, can easily distinguish whether that organ is contracted or relaxed, and at the same time if the bladder is full. In the latter case the uterus will be found to be pushed upwards and usually to the right. The bladder should then be quickly emptied by means of a catheter. If the uterus is relaxed it should be rubbed or kneaded. The organ then becomes firm, but if the hæmorrhage continues unabated it is evident that we are dealing with a laceration. If the bleeding only occurs with a relaxed uterus then we are dealing with a hæmorrhage from the utero-placental wound. If the bleeding occurs only in a somewhat less degree when the uterus is contracted, then we have a hæmorrhage resulting from atony complicated by a laceration.

If the laceration can be rendered visible—and in searching for such an injury we should include an inspection of the clitoris region, the hymeneal ring, the perineum, and the vaginal walls—and if the hæmorrhage is not too copious, a wad of absorbent cotton should be pressed against the parts until the afterbirth has come away. Then the lacerated parts should be united with catgut sutures. In other cases where the hæmorrhage is of a very copious character, the lacerated parts should be immediately united with catgut sutures without waiting for the after-birth to be expelled. If the injury cannot be seen, a careful manual examination of the vagina should be made to see if there is any perforation. If there is, a hot douche (45° to 50° C.) of a 1 : 4000 bichloride of mercury solution, will frequently check the hæmorrhage. If the injury does perforate into the vaginal cavity, then, after removal of the after-birth, there remains no other procedure at our disposal than the tampon.

If we are dealing with a uterine atony we should with all speed, either by Credé's method or manually, remove the after-birth and douche the womb with a hot 1:2000 solution of bichloride of mercury (according to Stæheli); the uterus should be rubbed in the meanwhile, and a hypodermatic injection of 1.0 gramme of ergotin given in the thigh. If these means are without avail, we must use the tampon.

In narrow genitalia the cervix must be caught with hooks and brought forward, but when there is plenty of room the procedure is a most simple one. The armamentarium consists of several strips of 30 per cent. iodoform gauze 2½ meters long (about three yards) and 5 centimeters (2 inches) wide. Each strip contains 1.7 grammes of iodoform; further, a tampon of moist salicylated cotton (4 per cent.) about the size of an English walnut for the mouth of the vagina.

After the tampon has been inserted, the operator should not fail to watch the uterus for an hour or so; or else a firm abdominal binder, into the folds of which a sad-iron or other weight has been placed, is applied, so that the weight comes over the fundus, preventing the relaxation of the womb in that direction. In severe cases an ice-bag may be placed over the abdomen, and one-half to one gramme of ergotin (Nienhaus') injected hypodermatically.

The uterine cavity, cervix and the vagina should all be tamponed, so that the possibility of an external and visible hæmorrhage being

merely transformed to an internal one is obviated, which could easily be the case if only the cervix or vagina were packed.

In the usual cases of atony and minor injuries or lacerations, the tampon can be removed the next day. In cases of severe injuries it should be left in place for forty-eight hours. The tampon should never be removed, however, without having another in readiness in case of an emergency. This rule is of the greatest importance, and should be always followed, at least in cases of severe injury.

In cases where more than five or six strips of gauze are necessary for the tampon, a few strips of salicylated gauze can be added advantageously. A mixed tampon of this kind should be practically odorless after having been kept in place for forty-eight hours.

We would raise another point of warning: in hurried packing of the uterus, etc., lacerations of the vulva in the region of the clitoris very easily occur, but can be prevented by due care.

In cases of rupture of the parts, besides a careful packing of fundus, cervix and vagina, the seat of the rupture itself and that part of the pelvis into which it opens must also be packed. Pressure must be maintained by a firm abdominal binder, augmented by cotton packing over the fundus, etc.

In one case of this kind resulting successfully, reported by Stæheli, no less than seventeen strips of gauze were used in completing the tampon.

In a few cases where large quantities of the gauze were used, iodine was traced in the urine. No unpleasant symptoms were ever observed as resulting from its use.

In conclusion, the obstetrician who has in his instrument case the iodoform tampon may rest assured that no woman need bleed to death from a post-partum hæmorrhage while under his care; and even if he be called in after the bleeding has begun, the chances are that he can save the case. After having applied the tampon in a case of atony, he can leave the patient without fearing a secondary hæmorrhage. Again, the tampon is easily applied; there is no need of a skilled assistant; and, finally, the procedure should not be used as a last resort, but be undertaken as soon as it is seen that the usual remedies have failed, and before the patient has suffered seriously from loss of blood.

LITERARY NOTES.

—The *New Albany Medical Herald* has been resurrected.

—The most recent addition to the list of medical journals is *The National Medical Review*, edited by Dr. Chas. H. Stowell, and published monthly in Washington, D. C.

—Mrs. Gladstone's first article in the series of "Hints from a Mother's Life," which she has written for *The Ladies' Home Journal*, will be printed in the April issue of that periodical.

—The first number of a new monthly—*The International Medical Magazine*—has been issued by the J. B. Lippincott Co. It contains some very interesting papers, and will doubtless prove a valuable addition to current medical literature.

BOOK REVIEWS.

A PRACTICAL RESUME OF THE MODERN METHODS EMPLOYED IN THE TREATMENT OF CHRONIC ARTICULAR OSTEITIS OF THE HIP. By Charles F. Stillman, M. Sc., M. D., Chicago., 118 pages. Price: Paper, 25 cents; cloth, 50 cents. Physicians' Leisure Series: Geo. S. Davis, publisher, Detroit, Mich., 1891.

This work has been compiled by the author with the object of acquainting practitioners and medical students with the most recent views held by orthopœdic writers upon the management of hip disease.

The subject is treated in a clear and concise manner, and apparently, is discussed with entire freedom from personal prejudice.

The individual methods of treating this affection as followed by Drs. H. O. Thomas, De Forest Willard, E. J. Chance, Bernard Barton, E. A. Andrew, Louis, Bauer, C. F. Taylor, L. A. Sayre, N. M. Shaffer, M. J. Roberts, R. W. Lovett, A. B. Judson, A. M. Phelps and W. Blanchard are fully presented, and take precedence to that adopted by the author, with which the volume concludes.

The book is copiously illustrated. The perusal of its contents will amply repay the reader.

DISEASES OF THE HIP-JOINT. FISKE PRIZE FUND DISSERTATION, No. XLII. Robert W. Lovett, M. D. Geo. H. Ellis, Boston, 1891.

This very attractive monograph upon the Etiology, Pathology and Treatment of Diseases of the Hip-joint was awarded the Fiske Prize in 1891. That the award was a just one the readers will be convinced after a careful perusal of the work.

The author first considers Acute Arthritis of the Hip-joint, which he considers a form of that disease which was first described by Mr. Thomas Smith, of London, under the title of Acute Arthritis of Infants. This affection which is a rare one, and one which is often confounded with other diseases, has been very clearly described by Dr. Lovett.

The author also describes acute synovitis and chronic serous synovitis of the hip-joint, and treats these subjects in such a manner that a careful study of his work will do much to correct the error which is often made of classing these cases with the disease we recognize as tuberculous osteitis or hip disease. The subject of tuberculous osteitis of the hip-joint is treated in a masterly manner, and the author's views upon the etiology, pathology and treatment of this affection are fully up to the times.

Dr. Lovett believes that the best results are obtained in this affection by constitutional and mechanical treatment, and is not in favor of early operative procedures, reserving excision of the hip-joint for those cases which have passed beyond the point where mechanical treatment can be applied with advantage, or for those in which it is practised as a life-saving measure. We confess that we have been disappointed in the ultimate results of excision of the hip-joint in many cases, and agree with the author that the results, as a whole, are not as satisfactory as those obtained by mechanical treatment. The author describes many forms of splints and apparatus employed in the treatment of this affection, and shows their application in many cases by means of excellent illustrations.

The work also contains articles upon Gummatous Osteitis, Arthritis Deformans, Charcot's Disease and Malignant Tumors of the Hip, and an excellent paper upon Congenital Dislocations of the Hip-joint.

It has seldom been our fortune to receive a work which shows such careful study of the subject matter treated, and which contains so much valuable information, and we most sincerely congratulate Dr. Lovett upon its authorship. The book is gotten up in a most attractive form, and the numerous photographic illustrations add much to its attractiveness.

THERAPEUTICS.

OLIVE OIL IN LARGE DOSES IN ILEUS.

Dr. Mitchell (*La Sémaine médicale*, No. 51, 1891) has used large doses of olive oil with success in the treatment of eight cases of intestinal obstruction. Seventy grammes (2½ ℥) of oil are taken every two hours, or even more frequently. One patient took 500 grammes (16 ℥) during one night, another a litre (a quart) in a few hours. An improvement took place in from three to twenty-four hours.

CONVULSIONS TREATED BY COMPRESSION OF THE CAROTID.

Dr. Leopold Roheim, of Budapest, publishes in the *Gyógyászat* a case of eclampsia which he had, after the failure of all ordinary remedies, successfully treated by compression of the carotid. The case, which is quoted by the *Pester Mediciñisch-Chirurgische Presse*, was that of a robust man of fifty-six, who had been suffering for years from cancer of the bladder, with occasional hæmaturia. The man had been attacked by a most violent eclamptic paroxysm, which was mainly confined to the left side. Dr. Roheim prescribed in vain musk, valerianate of zinc, bromide of potassium, asafœtida, hypodermic injections of morphia, enemata of hydrate of choral, and frictions with mustard, and at last employed compression of the carotid. After constant compression for some time of the right carotid the convulsions were suddenly arrested, the patient recovered normal respiration, and very soon felt quite well. Two or three slighter attacks followed, which were soon arrested by properly instructed attendants. The effect of the compression was so remarkable that Dr. Roheim earnestly recommends this treatment. He compressed the carotid with the index and second finger between the larynx and sterno-cleido-mastoid muscle backwards towards the spine, just as Trousseau and Blaud had recommended. He was equally successful in the case of a girl nine years old. He considers the *rationale* of the treatment to be that by compressing the carotid and at the same time necessarily the sympathetic nerve fibres, which closely follow the course of the artery, the excitability of the brain is allayed.—*Lancet.*

THE TREATMENT OF PLEURITIC EXUDATIONS BY MASSAGE.

Dr. P. Poliakow reports 10 cases of primary pleuritic exudations, 7 serous and 3 serofibrinous, which were benefited by massage of the affected half of the thorax. The massage is conducted in the direction of the lymphatics, the strokes all converging toward the axillary space. The rubbings at first are slight, but must later be energetic. The sittings are daily, and last from 10 to 20 minutes. By this treatment exudations disappeared in from 8 to 20 days, whereas, the other symptoms of the disease lasted from 9 to 35 days longer. The action of massage of the thorax is that of a counter-irritant, which can be applied daily. The massage also relieves the thoracic pain, and increases the strength of the muscles, thus rendering the amplitude of thoracic movement greater, a condition which beneficially influences the absorption of the exudation and dilatation of the compressed lung.—*Wiener Med. Presse.*

THERAPEUSIS OF SYPHILIS.

Ehrmann (*Centrabl. f. die ges. Ther.*, December, 1891) gives a review of the more recent methods of treating syphilis. The efficiency of mercurial inunction depends among other things on the number of the follicles in the skin, and no greater effect is obtained by rubbing in a larger quantity of the ointment, unless over a greater extent of skin surface. Mercurial injections in exact dosage have the advantage of not depending on the patient for being carried out, and of the distinction of the general from the local effects. The disadvantages in using soluble mercurial salts for injection are that they pass through the body rapidly, and that they produce toxic effects more easily. The remains of the syphilitic poison are still present, and it may multiply so as to give rise to relapses. With inunction as well as with the injection of insoluble preparations a depot of mercury is left which is gradually absorbed. According to Lichtenstein, relapses are more frequent after the injection of partially soluble preparations such as the salicylate of mercury than after the more insoluble such as the oleum cinereum. With the latter the injection is made weekly, whereas with soluble preparations it must be made daily, and thus one advantage over inunction is lost. Great care must be taken in cleaning the needle. As to the duration of treatment the limit is generally put down as three years, but it cannot be named for all cases. The author mentions two years. If after two years a relapse occurs (a rare event in the author's experience) or marriage be thought of, an extra year must be thrown in. The object is to avoid rather than to treat relapses. If a relapse occur within a few weeks after the discontinuance of the first treatment (by injection or inunction) one may be obliged to give mercury internally. At the end of three months, whether relapse or not, pills of the protiodide are given. After 6 months the patient gets seven injections of oleum cinereum at intervals of from 5 to 8 days, or 20 to 25 inunctions. This is repeated at the end of the first year. If there is a relapse in the first half year—and this must always be treated—mercury is given at the end of the third quarter. In the second year the inunctions or injections are repeated twice. If internal treatment is adopted, seventy-five pills of the protiodide correspond to some four injections. Mercury taken by the mouth and absorbed into the portal circulation may be excreted with the bile, and thus the full effect is not obtained. The treatment inaugurated by Fournier is a considerable advance; and though it is not time yet for a statistical statement, nevertheless it is certainly known that hereditary syphilis and severe and early relapses are decidedly diminishing.—*Brit. Med. Jour.*

MASSAGE OF THE PROSTATE.

Dr. Eberman presents the following conclusions as to the value of massage in prostatic disease: 1. It can be advised (*a*) at the decline of an acute parenchymatous inflammation where there remains difficulty in urination, the gland being still slightly swollen, and but little painful; (*b*) when the acute or chronic inflammation terminates in abscess, the massage having for its object the evacuation of the pus, and the resorption of the engorgement still present; (*c*) in cases of chronic parenchymatous inflammation with swelling; (*d*) in soft hypertrophy with uniform consistence of the gland. 2. Partial hard myomatous hypertrophy of the gland is not susceptible of massage; however, the massage in this case does no harm, and it can be tried, first introducing a pewter bougie into the urethra. Perhaps if the resorption of the tumor is not effected, the urethra, which has been modified by the irregularities of the hypertrophied prostate, may be again restored to proper calibre. The middle lobe of the hypertrophied prostate encroaches upon the cavity of the bladder, and by reason of its situation cannot be subjected to massage.—*Wratch.*

MEDICINE.

INTESTINAL OBSTRUCTION BY A MASS OF ROUND WORMS.

Dr. Heydenreich reports a case of intestinal obstruction, in which the Nélaton's operation was performed in the left groin with successful results, and the artificial anus was afterwards completely and permanently closed by a novel autoplastic operation. The subject, a child 11 years of age, came under the notice of the author on the ninth day of a severe attack of obstruction. The case having been diagnosed as one of intussusception, the idea of performing laparotomy was not entertained, as it was thought that the adhesions between the layers of intestines would be too firm to permit of the invaginated portion being drawn out. The small intestine was opened in the left groin, and two days later a bulky mass, made up of seven round worms, presented itself at the artificial anus, and was extracted. The young patient quickly recovered from the attack of obstruction, and the artificial anus was subsequently closed. Blood was passed from the anus during the period of obstruction.—*British Medical Journal.*

PATHOGENESIS AND TREATMENT OF SCOLIOSIS.

Dr. L. H. Petit, of Paris, according to the *Mercredi Médicale,* September 30, 1891, thinks that scoliosis is due to some vice of nutrition that acts at the same time upon the three elements of articulation—upon the bones, ligaments, and muscles—beginning in arrest of development in some point of ossification in the body of the vertebræ. The primary cause of this condition is not rachitis. Subjects attacked with scoliosis are usually lithæmics, neuropathics. Among them, neurasthenia makes itself felt in all the joints, which show a generalized relaxation. If the spinal column seems to suffer oftener from deformity, it is simply because such an important deviation cannot possibly be overlooked. To lithæmia and neurasthenia is frequently joined mental overwork, bad habits of poise while studying or during play. Growth and the establishment of puberty are also a tax. Dilatation of the stomach is of frequent occurrence among lithæmics, neurasthenics, and those suffering from scoliosis. In itself, it is a potent cause of debility. Treatment, exclusive of local or mechanical measures, consists in remedying, as far as possible, this dilatation, the lithæmic state, the neurasthenia, and menstrual disturbances.

WOOLSORTER'S DISEASE.

In the *Arch. de Méd. Expérimentale,* August, 1891, S. Lodge gives an account of broncho-pulmonary charbon with five cases. In a short historical sketch attention is drawn to the diminution of the disease since 1884, when precautionary measures were enforced. A few cases are still seen, owing to the occupation sometimes being carried on in private and with neglect of precautions. The smell and irritant properties of the dust are well recognized. The following are among the symptoms: *Malaise,* bodily fatigue and somnolence, coryza and lachrymation, cough, at first dry then with expectoration containing anthrax bacilli, and difficulty in taking a deep breath. Palpitation, nausea, and vomiting may be present, and the author looks upon a feeling of constriction at the base of the chest as pathognomonic. Physical examination reveals a bilateral pleurisy with moderate effusion and also foci of bronchopneumonia. The urine contains albumen and sometimes even sugar. The temperature is never above normal. When fatal, the disease lasts about six days. If the patient's occupation be unknown the diagnosis may be difficult. The prognosis should be cautious. Attention is drawn in the morbid anatomy to œdema in the tissues of the neck and mediastinum. There is fluid in the pleural and pericardial sacs. Besides injection of the bronchial mucous membrane there are elevations of a deep red color. The organisms are mostly found in the submucous tissue and also in the broncho-pneumonic foci. The spleen is usually normal in size. Prophylactic measures consist in ventilation and burning the dust collected in the ventilators, in the disinfection of hands, and the use of special clothes. Eating in the workshop is forbidden. The diseased wool should also be disinfected by super-heated steam—a point not enjoined in the regulations.—*Brit. Med. Jour.*

OSSIFYING MYOSITIS.

Macdonald (*British Medical Journal,* August 29, 1891) reports the case of a girl, four years old, in whom at two years of age hard nodules developed in numerous muscles of the head, neck, upper extremities, and trunk, occasioning rigidity and interfering with the movements of the affected parts. No hereditary factors could be elicited. Treatment was of no avail. Portions of the indurated parts removed were constituted of bone, having fibrous attachments of origin and insertion.

SURGERY.

THE EXCISION OF CARBUNCLES.

Wölfler (*Centralblatt für Chirurgie*, No. 40, 1891) writes as follows: The slow healing of carbuncles after treatment by the usual method of deep incisions, the gangrene of the skin, and the danger of renewed infection of the adjacent parts, as well as the formation of a frequently disfiguring cicatrix, induced Riedel, since 1883, to excise at once in all cases. For this purpose a circular incision is made around the infiltrated parts. This is followed by radiating incisions, starting from the periphery of the previous one, and perpendicular to it, in the direction of the sound tissue. The carbuncle itself is not incised. In this way, at least four skin-flaps are formed. These are cleared of inflammatory products. Once beyond the area of infiltration, the knife must be carried down to the fascia of the muscles and the whole of the morbid tissue removed, to bring the operation to an end. There is frequently very free bleeding, which is arrested by pressure and plugging. On the evening following the operation, the temperature tends to become normal; on the following day, the skin-flaps are brought nearer together. The central solution of continuity allows escape of secretions. Riedel praises this method for the following reasons: 1. A harmless loss of skin and subcutaneous tissue gets rid of a dangerous focus of inflammation. 2. The excision brings the local morbid processes to an end at once, and, consequently, all danger of general infection is removed. 3. The loss of sound tissue is small. 4. The healing is rapid. 5. The cicatrix is good.—*The Provincial Medical Journal*, December 1, 1891, p. 751.

INTRAPERITONEAL HÆMORRHAGES

Dr. Veit (Volkmann's *Samml. Klin. Vortr.*) discusses the question, why in some cases these hæmorrhages are arrested spontaneously, while in others this does not happen, and death ensues. The most frequent cause of intraperitoneal hæmorrhage is ruptured tubal pregnancy. The author's experience demonstrates that coagulation of blood takes place in the abdominal cavity, but more slowly than in other parts of the body. The action of pressure in arresting the bleeding cannot be relied upon, owing to the absence of counter-pressure in the abdominal cavity. The conditions for effective contraction of the vessels are also wanting in tubal pregnancy. It follows, therefore, that unless adhesions exist which limit the effusion of blood and lead to formation of an hæmatocele, the hæmorrhage will not be spontaneously arrested. If it takes place in a previously healthy abdominal cavity, the case usually terminates fatally. In laparotomies for intraperitoneal hæmorrhage, elevation of the pelvis is of great advantage for controlling the hæmorrhage; ligation of the bleeding vessels, as well as the uterine and spermatic arteries is also required.

THE ENLARGED PROSTATE AND ITS OPERATIVE RELIEF.

Keyes contributes a valuable paper on this subject in the *New York Medical Review*, Oct. 31, 1891. Eleven cases are submitted. In case one, through a perineal incision, a phosphatic stone was removed, and a small third lobe twisted off. Voluntary urination returned and remained for several years. Case two, aged sixty-five. Perineal incision, an outstanding section of the right lobe was twisted off, with much relief, but not complete cure. Case three, aged sixty-six. Perineal incision, middle lobe incised in V-shape and twisted away; cured. Case four, aged sixty-five. Suprapubic section, small projecting lateral growth removed, and urethral opening scraped as free as possible; cured. Case five, aged seventy. Clear urine, no albumen or pus, suprapubic operation, middle lobe pinched off with the rongeur; death from suppression of urine. Case six, aged sixty-six. Suprapubic, prostate around urethra cut and scraped away; cured. Case seven, aged fifty-nine. Suprapubic, large stone and third lobe removed with snare; cured. Case eight, aged sixty-six. Small stones and third lobe removed; good recovery. Case nine, aged sixty-five. Horse-collar enlargement with third lobe removed with scissors and rongeur; good recovery. Case ten, aged sixty. Also suprapubic, small calculus and prostatic bar removed; patient improving. Case eleven, aged sixty-one. Stone removed and also part of prostate gland; sank and died on the fifteenth day. This was a serious case from the start. The following conclusions were presented: (1) Prostatectomy is justifiable, and does what nothing else can. (2) The perineal operation is moderately less severe, but decidedly less reliable than the suprapubic; it should rarely be preferred, unless there be urethral complications. In very feeble men it may still be elected. (3) The operation is not justifiable with present statistics if the patient can be comfortable in catheter life. (4) No physical condition of the patient, short of a practically moribund

state contra-indicates operation. By it, in desperate cases, life is often actually saved, although the operation is a grave one and its mortality high. (5) With the rongeur, better than any instrument, the bladder outlet can be lowered, and polypoid or interstitial growths jutting into the prostatic sinus can be removed, and these points are more essential to a successful operation than is the taking away of a large portion of the prostatic bulk. The instrument next in value is the curved scissors, but the skilled finger is the most important of all. Most of the work has to be done by the aid of touch, as the bleeding soon becomes free and renders visual inspection impossible. Diuretin, perhaps, is of value when the kidneys are damaged. It certainly does no harm. (6) Chloroform alone, in my opinion, should be used as an anæsthetic for the kidney's sake. —*Univ. Med. Mag.*

OBSTETRICS.

TRILOBED PLACENTA.

Tarnier (*Journal des Sages-Femmes*, October 1st, 1891) exhibited before his class a placenta of this kind from an ordinary labor. It consisted of three lobes of considerable size, not of one main placenta with two placentæ succenturiatæ. The cord, contrary to rule, was inserted into the largest of the lobes, and the vessels ran thence to the middle and smallest lobes. On closer inspection the vessels were seen to run from lobe to lobe across the tracks of membrane which separated them. A similar condition is seen in velamentous insertion of the cord where the vessels run first over the membranes before they reach the placenta. This trilobed placenta was of no pathological importance in the particular case where it occurred, but an anomaly of the same kind might prove very serious in other cases, especially as regards the danger of leaving a lobe behind in the uterus.—*Brit. Med. Jour.*

THE TREATMENT OF ABORTION.

The question of the rational treatment of abortion is still undecided, and Dr. Chazan considers that evil results are often due to the too exclusive spirit of the partisans of both methods. In cases of threatened abortion all agree that it is necessary to combat uterine contraction by rest, opiates and every means in our power; but when the death of the fetus has already taken place, and pain and hæmorrhage are present, some authors endorse immediate delivery, while others think the presence of a dead fetus in a closed uterus absolutely inoffensive, and rely upon the expectant method, unless active interference is positively indicated. Opinions as to the treatment of those cases in which the abortion is still in progress are quite as diverse; but Dr. Chazan would divide these patients into two classes—those who have pain without hæmorrhage, and those who have hæmorrhage with or without pain. The former class may be treated safely by the expectant method; and even when hæmorrhage is present, immediate evacuation of the uterus is not always indispensable, and is sometimes impossible on account of the absence of assistants and instruments. The tampon may then be found to fulfil all indications. It may not only arrest hæmorrhage, but on taking it away, all the membranes are often found in the enlarged cervical canal. Contrary to the opinion of Dührssen, the expulsion of the entre placenta is the rule and not the exception. But the tampon, in order to achieve this end, must fulfil the following conditions: Its asepsis must be perfect; it must arrest hæmorrhage and strengthen the pains. The first is easily attained by bathing the genitals and vagina with an antiseptic solution, and making the tampon of iodoform gauze, or cotton dipped in a 3 per cent. solution of carbolic acid. In multiparæ the tampon may not always arrest hæmorrhage, and we may then have recourse to the intracervical tampon, which is generally more efficacious than the colpeurynter. First fill the posterior *cul-de-sac*, and then the cervix. Tampons made of cotton must not be left in place more than 5 or 6 hours. When hæmorrhage continues after the abortion, the expectant treatment can lead to no result; but the decision as to when and how to interfere must depend upon the general state of the patient and the condition of the contents of the uterus.—*Gazette de Gynécologie*, November 1, 1891.

PROLAPSE OF PREGNANT UTERUS: "EXTRA-ABDOMINAL DELIVERY" AT TERM.

F. Stein (*Wein. Med. Blätter*, December 3d, 1891) was called in to a woman already several hours in labor. The midwives declared that labor was impeded by a great tumor growing from the vulva. The patient was a weakly dwarfish woman, about 22 years of age. She had already borne a child. Stein discovered a round mass as big as a child's head, which had descended out of the pelvis with its contents. The os was dilated, and the child's occiput presented. In fact, the greater part of the uterus, except the

fundus, has been forced out of the pelvis by the pains. At the end of two hours the child was delivered, slipping out of the uterus as though from a sac. The pains had been strong and regular throughout. All Stein could do was to support the uterus during the pains, lest it should protrude further or tear off from some of the important structures which serve as its ligaments. The child was well developed and living; it was born at term. The uterus was carefully replaced, with antiseptic precautions, after delivery. No evidence of malformed pelvis could be detected, the measurements being normal. After recovery the patient was able to return to work, a suitable pessary having been applied. Stein observes that it was most instructive to watch the progressive dilatation, gradual thinning, and ultimate effacement of the os as the pains progressed.—*Brit. Med. Jour.*

ACUTE OÖPHORITIS COMPLICATING PREGNANCY.

Three cases of this unusual condition are described by Coe (*American Gynecological Journal*, 1891, No. 9). In one, an exacerbation of a chronic oöphoritis followed overheating and sudden exposure to cold. Recovery ensued without the interruption of pregnancy.

In the second case, septic infection followed abortion, and a second pregnancy supervened. Ovarian abscess was diagnosticated, and stimulants were freely administered. A large quantity of pus appeared in the urine, although there was no evidence of cystitis. The patient's pain and temperature subsided. After gaining for some time, fever and sweats again appeared, when labor was induced. After the termination of pregnancy, the patient progressed steadily toward recovery, and ultimately became perfectly well.

The third patient was a multipara, who had had pelvic inflammation; at seven months of her pregnency she had a chill and fever, with pain over the right ovary. She recovered from this, and was well until her confinement. The third day after labor she had a chill and fever, and complained of pain in her right side. After intervals of gaining and losing, ovarian abscess was diagnosticated, and an incision was made over a mass in the pelvis. The diagnosis was correct, and the tube and ovary of one side were removed. The patient was much better afterward. Recovery followed in four weeks after the operation.

In writing of treatment, Coe advises a largely expectant method. Constipation is to be avoided, and hot applications may be used over the area of pain. Abdominal section is most successful when performed before the fifth month.

GYNÆCOLOGY.

PAPILLARY CYSTOMATA OF THE OVARY.

J. W. Williams, (*Bull, of Johns Hopkins' Hosp.*, December, 1891) disagrees with those authorities who trace this disease to Wolffian elements. Papillomata arise, he believes, in the Graafian follicles, in the germinal epithelium, or from ingrowths of the epithelium of the Fallopian tube into the stroma of the ovary, but this mode of origin is, in his opinion, not yet absolutely proven.—*Brit. Med. Jour.*

ENDOMETRITIS AND ACUTE INFECTIOUS DISEASES.

Massin (*Archiv. f. Gynak.*, vol. xl Part 1, 1891) examined the uterus in twelve cases of relapsing fever, two of pneumonia crouposa, two of typhoid fever, one of dysentery, and one of acute diffused peritonitis of uncertain origin. Not only was inflammation of the endometrium discovered, but the inflammatory process extended to the muscular tissue. There were hæmorrhages in the endometrium, very extensive in the cases of continued fever and mixed infection. Massin lays great stress on the fact, shown by his researches, that the uterus is actively involved in acute infectious diseases.

PELVIC MASSAGE.

Dührssen (*Berliner klin. Wochenschrift*, 1891, Nos. 44, 45, and 46) thus concludes an elaborate paper on Thure Brandt's method, in which he gives a detailed account of the treatment of eighteen cases: If endometritis is absent, the thorough application of massage will stretch or separate bands or adhesions. Organs which are fixed may be more quickly rendered movable by Schultze's method, practised under narcosis; massage should be employed subsequently in order to prevent the formation of fresh adhesions. Laparotomy is no longer justifiable in cases of retroflexion with fixation and chronic oöphoritis and peri-oöphoritis until massage has been thoroughly tried, provided that the trouble is not of gonorrhœal origin. Systematic elevation of the uterus is often sufficient to cure retroflexion. Parametric exudations which were formerly purulent foci are unsuitable for massage; ordinary exudations are generally quickly absorbed.

A NEW METHOD OF HYSTEROPEXIE.

Matlakowski (*Der Frauenarzt*, Hft. 9, 1891) recommends the following method, which he performed with success in three cases: A short incision is made in the linea alba one to two centimetres above the symphysis. The hand is introduced into the abdomen and the uterus raised. The round ligaments are then exposed on each side. Their peripheral portions are ligated and they are cut at about the distance of six centimetres from the uterus and the central end is grasped with a pair of forceps. The peritoneum, fascia, and recti muscles are perforated one to two centimetres to the side of the first incision, and the central portion of the ligaments drawn through these openings, the uterus being held in position; they are fastened to the anterior abdominal wall under the skin by a ligature. The primary incision is then closed and the operation is thus completed.

A CASE OF PUERPERAL PERITONITIS TREATED BY AMPUTATION OF THE UTERUS: RECOVERY.

Dr. A. Lapthorn Smith has reported in the *American Journal of Obstetrics*, January, 1892, the following interesting case: A woman delivered for the second time had an adherent placenta, which was removed piecemeal, with great difficulty, in the twelve hours succeeding delivery, partly by a midwife, partly by Dr. Smith. Forty hours later there was a chill, followed by high fever, although antiseptic injections had been used. Two days after labor a general peritonitis apparently developed. No attempt was made to further clean out the uterine cavity, but the abdomen was opened on the following day, and no evidence of peritonitis discovered. The uterus, as the seat of infection, was then removed, by the extraperitoneal plan, with pins and a nœud. In conclusion Dr. Smith advises:

(1) The temperature should be taken every day after every confinement, and, on the slightest rise, vaginal douches of permanganate solution should be commenced.

(2) If the temperature continues to rise, the douches should be made intrauterine.

(3) If there is no improvement at the end of twenty-four hours, scrape out the uterus with the finger or with the curette, apply strong tincture of iodine, wash out the uterus, and drain with iodoform gauze.

(4) If the case proceeds from bad to worse, and peritonitis sets in, perform exploratory incision, and if no other evident cause can be found remove the uterus.—*Univ. Med. Mag.*

ETIOLOGY AND THERAPY OF WEAK LABOR PAINS IN OLD PRIMIPARÆ.

Borner (*Der Frauenarzt*, Hft, 9, 1891) attributes the weak labor pains so often observed in old primiparæ to a beginning retrograde metamorphosis of the entire generative system. Absolute absence of pains in old primiparæ is to be considered the first indication of the approaching climacteric. The uterus of an old primipara has not the activity or physiological strength of one that has borne children. This the author considers the cause of tardy labors in these cases, and the reason why there is so much risk to both mother and child, requiring careful watching on the part of the physician, and often the use of forceps, turning, sometimes even perforation, or incisions into the portio vaginalis in cases where the os does not dilate sufficiently.

PÆDIATRICS.

THE NON-IDENTITY OF DIPHTHERIA AND THE SCARLET-FEVER DIPHTHERIA.

Heubner (*Jahrbuch für Kinderheilkunde*, xxxi., 1890, p. 56) maintains that there is a distinct difference between primary diphtheria and the diphtheria which occurs in connection with scarlet fever. In five cases of the latter disease he could not once find Loeffler's bacillus, which is generally regarded as the cause of primary diphtheria, while in cases of primary diphtheria he never failed to find the bacillus. Likewise, Kolisko and Paltauf did not find the Loeffler bacillus in cases of angina from diphtheritic scarlet fever.

As further proof that the two diseases are distinct he makes the following statements: In scarlet-fever diphtheria the tissue necrosis is not so marked as in primary diphtheria. Necrosis, and scarlet-fever diphtheria which begins with it, develop from the scarlet-fever angina in the latter part of the first week, and become clinically evident by the symptoms of septic infection, especially by swelling of the lymphatic glands, and by the course of the temperature; the gradual fall of the temperature from the fourth day does not take place, or the temperature again rises when necrosis develops. Moreover, scarlet-fever diphtheria, unlike primary diphtheria, very seldom results in laryngeal stenosis and diphtheritic paralysis.

A CASE OF SECOND ATTACK OF WHOOPING-COUGH.

The possibility of second attacks of pertussis is denied by Rillet, Barthez, and Bergeron. Westen, however, has recorded one case, Trousseau two, and Roger five. The most recent instance is contributed by Legendre (*Rev. mens. des Mal. de l' Enfance*, November, 1891), and constitutes the ninth case of the kind recorded. The patient was a young woman of twenty-five years, who had had pertussis at the age of ten years, at the same time that a sister and brother were affected. Fifteen years later the patient was brought to the author for a cough, which was regarded with suspicion because of the existence of tubercular disease of the lungs in several members of her family. Careful examination revealed no tubercular lesions; and the diagnosis was not made clear until, during a visit of the physician, the patient gave a most characteristic "kink." The girl was then found to have contracted this second attack from a child in the house suffering from severe whooping-cough.

ACUTE RHEUMATISM IN CHILDREN.

A. A. Kisel (*Med. Obozerenië*, No. 20, 1891) reviews a series of 38 cases of acute articular rheumatism observed in patients aged from 2 to 16. Not more than 16 out of the 38 patients complained of pain about joints; in the remaining cases some other symptoms (most frequently referable to the vascular system) were predominant. The author lays down the following general propositions: (1) Heredity plays a very important part in the causation of rheumatism in childhood. A careful inquiry into family antecedents rarely fails to elicit the fact that the child's parents are rheumatic subjects. (2) In children the course of rheumatism very seldom resembles that of an acute infectious disease. (3) Infantile rheumatism very commonly runs a latent course. (4) Cardiac complications occur more frequently, and are of a more severe type in children than in adults.—*Brit. Med. Jour.*

PURULENT VULVO-VAGINITIS IN LITTLE GIRLS.

Chaumier (*Poitu Medical*, October, 1891) calls attention to the purulent vulvo-vaginitis of little girls, which, according to certain authors, owes its origin to blennorrhagic infection. The writer holds that the disease may also be due to other causes, notwithstanding the presence in the discharge of the gonococcus of Neisser. The disorder is contagious, and is of more frequent occurrence in large cities than in the country. It always exhibits the same aspect, characterized by a thick purulent discharge, agglutination of the great lips, and retraction of the vulva and vagina, but without complicating the urethral canal. Vulvo-vaginitis is often accompanied with a slight feverish reaction, loss of appetite, frequent and painful urination, the pain being due solely to the passage of the liquid over inflamed parts. In a case related by the author the disease was complicated by an arthritis of the knee-joint. If the malady is left to itself it may last a long time, but under proper treatment it will generally yield in from two to two and a half months. The treatment consists in the external applications of lotions and in the vaginal injections of corrosive sublimate.

HYGIENE.

PHYSIOLOGICAL RELATION OF ALCOHOL TO FOOD.

Dr. W. H. Porter (*Med Record*) says: Three classes of proximate principles are necessary to maintain life, and must be supplied as food-stuffs.

That the term food-stuff should be limited to those substances which contain at least one element from each of these three classes in its composition, viz,, an inorganic, a CHO, and a CHNOS element.

That the first act mechanically, the second as non-nutritive stimulants, and the third as true nutritive elements which enter into the essential construction of all the tissues and glands of the body.

That the use of the second class or CHO compounds—including alcohol—when taken in excess of the absolute demands of nature, all tend to overtax the oxygenating capacity of the system and prevent a complete oxidation of the proteids or CHNOS bodies.

That this continued over-stimulation and the half-starved condition arising through this excessive use of the CHO or non-nutritive and alcohol-forming compound, tend most decidedly to weaken the vital forces, develop diseased conditions, and create the habit on the part of the system to take to alcoholic stimulation.

That alcohol *per se* is no more poisonous than fat, sugar, and starch, but they are all factors in depriving the system of its full quota of oxygen to act upon the proteids, and from this incomplete transformation of the latter or CHNOS elements, nutrition is impaired and an almost unlimited number of toxic bodies produced.

That alcohol and the chemical elements which enter into its atomic construction, and the transformation they undergo in passing through the system, and the final products eliminated from the body, are practically the same as follow upon the introduction of fat, sugar and starch.

That alcohol should only be classed as a medicinal agent, and never be used in health as a common article of food.

That to combat most satisfactorily and successfully the alcoholic habit, the proteids or CHNOS food-elements should be the principal substances used, and the CHO compounds of all kinds should be avoided as much as possible.

That there is a common tendency to feed improperly the animal economy from infancy to the grave, and to this false habit all the ills of the human race are largely traceable, and in it we find the chief factor in producing and maintaining the alcoholic habit.

DUST AND DUSTINGS.

"It is our littleness that sees no greatness in a trifle." This is true if success is a multiple of careful details. It is true, therefore, of perfection in every art and work, even the commonest, and among such a contemporary has assigned a place to the seemingly menial art of dusting. For, as he says truly enough, there is an art in dusting, and it is one which on every ground deserves far more studious cultivation than it usually receives. Different observers have from time to time described the components of ordinary dust, and these, it is needless to say, exhibit special characters in almost endless variety. Mineral matters, animal and vegetable débris, morbid germs—whatever, in fact, is light enough and small enough to remain for a time suspended in air, come under this common and generic but far from harmless term. The spread of cholera and exanthematous diseases has, no doubt with perfect truth, been attributed to its influence. It is clear, then, that the method to be employed for its removal is a matter of some importance. As regards this, we need hardly discuss every suggestion of housewifery. Some would pin their faith, not without reason, to the damp duster rather than the dry one, but this will not suffice in itself, and, moreover, every kind of furniture does not bear such treatment. Where possible, of course, it is of the two the more effectual plan. Above all, however, it is needful to remember that the object aimed at is not displacement of dust only, but its removal, and for this purpose a combination of thorough daily ventilation by open doors and windows, with careful sweeping, followed by at least displacement of any dust still remaining with a cloth, is the only method alike feasible and effective. All over-crowding with furniture or with woven fabrics is to be avoided. Bed curtains and valances are no less objectionable, and bare floors are more wholesome than the choicest carpet. Nowhere is care in these particulers more justified or more imperative than in the crowded homes of the poor. Let us but mention one other point—the healthy effect of sunlight. It is now admitted that some disease germs lose their power on exposure to light. In this fact we have a standing protest against the custom of darkening rooms with lowered blinds, or that æsthetic error which covers the window space with crossed curtains.—*Lancet.*

AN ATTEMPT TO RENDER TOBACCO HARMLESS.

Smokers may be pleased to learn that Dr. Gautrelet, of Vinchy, claims to have discovered a method of rendering tobacco harmless to mouth, heart and nerves, without detriment to its aroma. According to him, a piece of cotton wool steeped in a solution (five to ten per cent.) of pyrogallic acid, inserted in the pipe or cigar-holder, will neutralize any possible effects of the nicotine. In this way not only may the generally admitted evils of smoking be prevented, but cirrhosis of the liver, which in Dr. Gautrelet's experience is sometimes caused by tobacco, and such lighter penalties of over-indulgence as headache and furring of the tongue, may be avoided. Citric acid, which was recommended by Vigier for the same purpose, has the serious disadvantage of spoiling the taste of the tobacco.—*Science.*

SAFE QUININE.

(LEVI.)

The troublesome buzzing of the head which follows the administration of large doses of quinine is stated by Dr. Levi, a Central American physician, to be averted by the following combination:

Quinine sulphate	gr. lx.
Pepsin	" lx.
Capsicum	" vj.
Ginger	" xij.
Sodium bicarbonate	" lx.

Mix, and divide into twelve powders.

One of these powders is the dose for neuralgia, but more or less of the combination may be taken according to the nature of the disease. In rare cases quinine causes vomiting and purging symptoms, which are averted, says the *Satellite*, by Dr. Levi's prescription.

MEDICAL CHEMISTRY.

THE ANALYSIS OF RUSSIAN BREAD.

According to *Reuter*, the Russian papers of last Monday published the official analysis of the adulterated flour recently bought by the Municipality of St. Petersburg city. The result would appear to show that it was not adulterated to such an extent as the *Novoe Vremya* announced some days ago. While this statement appears in a negative form, yet the fact that it is qualified by the sentence "to such an extent" does obviously indicate a certain amount of adulteration. The exact details of an analysis of Russian bread carried out in our laboratory appeared in our columns last week, and the results showed an adulteration, even in this specimen which was regarded as unusually good, equal to the addition of ten pounds of foreign substances to every hundredweight of flour. Our report was read with very general interest, inasmuch as it demonstrated distinctly that the flour had been tampered with, not, perhaps, to an excessive extent, as has been believed, but still to an extent which is both unpardonable and unjustifiable. In respect to the results, it is so far satisfactory to learn that our report is practically confirmed by the Russian official analysis, although the *Novoe Vremya* maintains that the official analysis is misleading, and it cites the opinion of several experts in support of this contention.—*Lancet.*

DETECTION OF MORPHINE IN THE URINE.

A paper by Professor Theodore G. Wormley, of the Pennsylvania University, on the recovery of absorbed morphine from the urine, the blood, and the tissues, has recently appeared in the *Chemical News*. The paper, which appeared in several issues, is much too long to attempt to abstract, but the gist of it is given in the following general considerations: In the use of amyl alcohol for the extraction of morphine from the urine, the urea taken up with the morphine interferes more or less with the purification of the alkaloid. In a residue consisting of a mixture of this kind, the urea, as such, may, as we have found, be decomposed by heating the mixture in an air oven for a few hours at 135° C., without any appreciable loss of the morphine.

But the presence of the products of the decomposition of the urea prove about as objectionable as that of the urea itself. Since urea is freely soluble in water, whilst morphine is only sparingly soluble, it might be inferred that those substances could thus be readily separated.

This is true in regard to pure mixtures, and also when the morphine has assumed the crystalline state; but when present in only minute quantity, the alkaloid seems to be so closely adherent with the urea and coloring matter that these substances are largely dissolved together. Experiments made in regard to the adaptability of isobutyl alcohol for the extraction of morphine from complex mixtures, especially from the urine, show that on treating excess of finely powdered morphine with the hot alcohol and allowing the mixture to stand sixteen hours, it was found that 1 part of morphine was held in solution by 110 parts by weight of the alcohol. Under the same conditions, 1 part of urea was retained in solution by 49.8 parts by weight of the alcohol. It would thus appear that morphine, while rather freely soluble in isobutyl alcohol, is slightly less soluble in this liquid than in amyl alcohol; whereas urea, on the other hand, is somewhat more freely soluble in isobutyl alcohol than in amyl alcohol.—After *Chem. and Drug.*

IODO-NAPHTHOL.

M. Braille, describes a compound of iodine with *b*-naphthol (*Union Phar.*) It is stated to be prepared by mixing an aqueous solution of 24 grams of iodine and 27 grams of potassium iodide with an aqueous solution of 110 grams of *b*-naphthol and 40 grams of caustic soda, and adding to the mixture gradually a solution of sodium hypochlorite corresponding to ten times its volume of chlorine. The iodo-naphthol is precipitated as a greenish-yellow powder, which is collected and washed several times with water and dried in the dark. When exposed to the light, the greenish color becomes intensified rapidly. The product is said to be odorless and tasteless, insoluble in water, almost insoluble in alcohol and acetic acid, partially insoluble in ether and very soluble in chloroform.

ALTERATIVE.

Dr. Fyke, in the *Courier of Medecine* claims the following to be an excellent prescription in all wasting diseases:

℞

Hydrarg. bichlor.	grs. i,
Lib. arsen. chlor.	ʒ ii.
Tr. ferri. chlor.,	
Acidi hydrochl. dil.	āā ʒ ss.
Syr. limonis	ʒ ii.
Aquæ dest.	q. s. ad ʒ vi

M. To adults a teaspoonful every four hours.

NEWS AND MISCELLANY.

A. C. E.

In the famous old a c. e. mixture,
Both ether and chloroform stay;
But neither of these is a fixture,
As a safe anæsthetic to-day.
Some countries are partial to neither,
Tho' England gives chloroform sway;
"How happy could I be with *ether*,
Were t'other dear charmer way."

L. Lewis.

THE PHYSICIAN.

The following is the translation of an epigram written by Cordus in the sixteenth century:

The Physician like an angel seems
When he in the sick room brightly beams,
And like unto a god is he
When he's removed the malady.
But in a different light we view
The doctor when his bill is due;
Our alter'd eyes we at him level
As though he were the very devil.

Dr. Carl, in Med. Brief.

PROPRIETARY REMEDIES.

Thirty years ago Great Britain derived from patent medicines a revenue of $210,000. The same tax now yields $98,500,000 a year. All this increase is at the expense of the gulled public; the honest apothecary and the doctor being large losers.

INTERNATIONAL GYNÆCOLOGICAL AND OBSTETRICAL CONGRESS.

Dr. Jacobs, General Secretary to the Congrès Périodique International de Gynécologie et d'Obstétrique, which will hold its first meeting at Brussels in September, announces that the following subjects have been chosen for special discussion: (1) Pelvic Suppurations, to be opened by M. Segond, of Paris; (2) Extrauterine Pregnancy, by Dr. A. Martin, of Berlin; (3) Placenta Prævia, by Dr. Berry Hart, of Edinburgh.

INSANITY AN EXCUSE FOR ADULTERY.

A curious medico-legal point was raised in a suit tried a few days since in the Divorce Court. The action was brought by the husband, and the adultery of the respondent was admitted, she having herself taken the trouble to communicate the fact by letter. There was, however, evidence to show that she had left the conjugal domicile under the influence of delusions, and her insanity was virtually established. It was therefore urged on her behalf that under these circumstances she was not legally responsible for her actions. The judges held, however, that though insane she had retained sufficient mental capacity to be aware of the nature and consequences of her actions, and on this ground the divorce was accorded. So far so good, but from a medical point of view, it were much to be desired that mental alienation *per se* should be admitted as a reason for divorce. Even if the demented wife should subsequently recover her reason, it is eminently undesirable that she should regain the right to reproduce and thus to perpetuate the morbid strain. Our divorce laws were based on social and moral considerations, the still small voice of the physiologist not having made itself heard. Pathological, like criminal proclivities entailing the loss of the civil status, ought to be recognized as unfitting their possessor for the conjugal relationship. It is fully as important to the community to prevent the multiplication of the insane or the mentally unstable as to check the manufacture of juvenile criminals. Unfortunately, the authorities who show the greatest solicitude to preserve the breed of horses from contamination display a very manifest reluctance to protect the human race from similar contamination. Perhaps, with the march of intellect, public opinion may by-and-by be educated up to the point of agitating for the enforcement of physiological laws.—*Med. Press.*

DURATION OF LIFE OF VARIOUS ANIMALS.

The *Scientific American* give the following estimates of the duration of the life of various animals: Elephants, 100 years and upward, rhinoceros, 20; camel, 100; lion, 25 to 70; tigers, leopards, jaguars, and hyenas, (in confinement) about 25; beaver, 50; deer, 20; wolf, 20; fox, 14 to 16; llamas, 15; chamois, 25; monkeys and baboons, 16 to 18; hare, 8; squirrel, 7; rabbit, 7; swine, 25; stag, under 50; horse, 30; ass, 30; sheep, under 10; cow, 20; ox, 30; swans, parrots, and ravens, 200; eagle, 100; geese, 80; hens and pigeons, 10 to 16; hawk, 30 to 40; crane, 24; blackbird, 10 to 12; peacock, 20; pelican, 40 to 50; thrush, 8 to 10; wren, 2 to 8; nightingale, 15; blackcap, 15; linnet, 14 to 23; goldfinch, 20 to 14; redbreast, 10 to 12; skylark, 10 to 30; titlark, 5 to 6; chaffinch, 20 to 24; starling, 10 to 12; carp, 70 to 150; pike, 30 to 40: salmon, 16; codfish, 14 to 17; eel, 10; crocodile, 100; tortoise, 100 to 200; whale, estimated, 1,000; queen bees live 4 years; drones, 4 months; worker bees, 6 months.

" Stanford E. C. Chaille, Joseph Jones, A. W. de Roaldes, ... *NEW ORLEANS.*
" C. B. Bringham, R. B. Cole, Levi C. Lane, J. Rosenstirn, ... *SAN FRANCISCO*

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne I find G. H. Mumm & Co's Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it, not only for its purity, but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M. D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

No Openers required. FOR USE IN SICK ROOMS and families. By a recent and most practicable invention, no openers in future will be required for G. H. Mumm & Co.'s Champagne.
To break the wire—bring the small seal to a horizontal position, and bend from side to side till one of the wires is broken, pulling upward removes top of cap and wire—done in an instant.

Pronounced by Connoisseurs the Champagne par excellence.

FRED'K de BARY & CO., New York, Sole Agents in the United States and Canada.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

THE RADICAL CURE OF NON-CONGENITAL INGUINAL HERNIA.

By PROFESSOR PRENGRUEBER.*
PARIS, FRANCE.

Gentlemen:—I am about to operate before you upon this patient, a man 55 years old, who is suffering from an inguinal hernia in the left groin. This hernia is of about ten years standing, it developed slowly and progressively. Actually its weight, if isolated, would be about two pounds. It can be easily and completely reduced. After its reduction has been effected, one is struck with the considerable dilatation of the inguinal canal. In truth, the canal has entirely disappeared, and nothing is left but a large orifice which is a fusion of the internal and external orifices, without any intervening passage. On examination of the right side, we see that here the inguinal canal is also greatly dilated, and at its opening there are also slight evidences of hernia.

This extreme dilatation of the orifices of both inguinal canals is, I believe, the reason our patient has suffered so much from hernia. In this case there are actually no traces of any adhesions, and the hernia is completely and easily reducible. Before proceeding to undertake the radical cure of this case, which naturally involves an operation, we must have decided indications which will fully justify our taking such a step in a patient of the comparatively advanced age of fifty-five. Our indications, which fully warrant the performance of the operation are the following: Although the reduction of the hernia is easily accomplished, its retention in place is most difficult and troublesome owing to the size of the inguinal orifice. The patient has resorted to many styles of trusses, but all are either incapable of retaining the hernia in place or else cannot be tolerated by the patient. The hernia invariably, upon the slightest exertion on the part of the patient, will fall above or below the pad of the truss. The various experiments result in the production of intestinal irritation, or else inflammation, sufficiently violent and menacing to justify the performance of the operation for the radical cure of the hernia. Thanks to the size of the inguinal ring there has been no strangulation in the case, but it is very likely that this complication might occur at any time, necessitating an immediate surgical interference under circumstances much less favorable, and far more dangerous than those existing at present.

This question of the justifiability and value of the radical cure for hernia, has, as you know, excited a vast amount of controversy among surgeons. After the attempts made by surgeons of the last century to perfect this operation, the results they have obtained caused the procedure to fall into disrepute in the beginning of this century. This disfavor was entirely justifiable, since it was then impossible to prevent accidental traumatic infection, but with our present knowledge of antisepsis the operation is rendered quite inoffensive, although very possibly capable of considerable improvement. All the same, as had been said, the subject is still one of controversy among surgeons: First, in regard to the adequate indications for its performance; second, in regard to the efficacy of the operation itself.

Concerning the indications for the radical cure, one is to-day indisputable, that is for strangulated hernia. In the operations for strangulated hernia the "radical cure" is embraced in the final step of the operation. The intestine having been reduced, it is necessary to resect the hernial sac. Without in any way adding to the dangers of the first step in the operation for strangulated hernia, its conclusion by the resection of the sac will only tend to lessen the dangers of an ultimate relapse. Finally, in case of a relapse

*Delivered at the *Hôspital St. Louis*, Paris; translated from *Le Bulletin Médical*.

the hernia will be more easily held in place and better tolerated.

The indications for the operation in cases of irreducible herniæ are to my mind equally forcible. A hernia of this kind is a source of constant pain and perpetual menace to the patient. Trusses are not tolerated, and even specially designed apparatus gives but a poor sort of satisfaction. The radical cure will at least transform the irreducible hernia into a reducible one, which can be retained by a very simple truss, and this alone is surely a decided gain.

Regarding the operative difficulties in such cases, I would say that the irreducibility of these herniæ may be due to either of two different causes: There may be adhesions of the intestine to the hernial sac, or else the presence of the epiploon or omentum in the sac may constitute the obstacle hindering the reduction, either by reason of adhesions or else by reason of its volume. It is not rare, in fact, for the omentum to become tumefied or swollen, and to become chronically inflamed while incarcerated in the hernial sac, forming a sort of stopper or cork in the inguinal ring which will prevent reduction. The operative technique, as well as other difficulties, will vary with indications of this or that case.

A third order of indications, and one which has been freely discussed and disputed, is, as in the case of our patient, a difficulty in keeping the hernia in place. In order to be justified in operating upon this class of cases, it is evident that the reality of this difficulty must be fully established, and that the various styles of suitable trusses have been conscientiously tried. If this has been done, we are surely justified in not leaving the patient menaced by constant suffering, and the possible accidents of rupture or strangulation.

But before deciding upon a surgical interference the general condition of the patient should be most carefully inquired into. As I have already said, the age of our patient (fifty-five years) has caused some hesitancy on my part, and I would not have concluded to operate had the patient not been robust, active, and well kept. In case, however, the patient were feeble, poorly nourished, or had any suspicion of pulmonary trouble, I would refuse to operate. Even in a case of irreducible hernia, were the patient's condition bad, we would be justified in confining the operation to a simple kelotomy without attempting the radical cure. In patients of advanced age, simple kelotomy constitutes a grave procedure, and any prolongation of the operation should be rejected.

These constitute the indications and contra-indications for the radical cure of hernia. What at present constitutes the dangers and the results of the procedure?

The operative dangers, in a suitable case, and when the operation is conducted with antiseptic precautions, may be regarded as nil. I, for my part, have performed the operation nearly fifty times, and my statistics, as also those of other antiseptic surgeons, show no death. I only once had an accident, which very fortunately was not serious, but which I will refer to in order to show you the importance of maintaining strict asepsis.

The patient in question was operated upon by me in the Hôtel-Dieu, and an abscess formed on the fifth day at the neck of the sac. The catgut employed as the ligature had evidently been improperly sterilized and had acted as the exciting cause for this infection. It would, you will therefore see, gentlemen, be useless for you to attempt the operation for the radical cure of hernia, did you not fully comply with all the requirements of strict asepsis.

Regarding the therapeutic results which one may hope for, it will first be necessary to distinguish two different operative conditions.

Among herniæ, one variety, as you know, is produced by force, strain or rupture, and occurs in patients, with strong abdominal walls, but whose vocation in life compels repeated and violent exertions, these would include butchers and bakers for instance. These may be classed as accidental herniæ. The second variety of herniæ comprises those resulting from feebleness, or constitutional herniæ. These are the herniæ met with among aged and debilitated subjects. There exists but slight resistance of the abdominal wall. When speaking of the ultimate results of this operation for radical cure, I also add to this last group congenital herniæ, caused by malformation, a veritable defect in the abdominal wall.

The herniæ of force promise the best results after the operation for radical cure. The recovery is complete, and it is lasting. Two cases of this kind come to my mind, both of which I operated upon over two years ago. In both the cicatrices remained firm and solid, and in spite of the most fatiguing and continued labor on the part of the subjects, there has been no evidence of recurrence of the herniæ. I still advise them to wear a truss, but more as a precaution than a necessity. In one of these cases the hernia was very voluminous, and I was only able to reduce it after the most difficult and laborious operation of the kind that it has yet been my

lot to perform. In the other subject, the continued strain which his occupation has compelled him to work under since the operation has been sufficiently violent to give rise to a hernia on the side not operated upon, while the old hernia has given no evidence of reappearing. These results are very satisfactory.

The herniæ of feebleness, on the contrary, will only result in moderate success when treated by the radical cure. In these cases one may be able to suppress the hernia, but its cause itself, the predisposition caused by the feebleness of the abdominal walls, remains after the operation has been apparently sucessfully completed.

The least successful case that I ever operated upon was that of a child four years old. The hernia was congenital, and returned four months after the operation, as large at it had been at first. But the subject was very feeble, and subsequently died of tuberculosis.

The technique of the operation for the radical cure is simple enough. While maintaining strict asepsis, I do not insist upon all the technical minutiæ, but am satisfied with knowing that the patient's parts to be operated upon, instruments, operator, and assistants are clean. The incision is made cautiously, line by line, until the sac is reached. The laying bare of the sac will be found especially difficult if at the moment of incision the hernia slips back into the abdomen. To avoid this make the patient cough so as to bring the hernia down before administering ether, and avoid the slightest attempt at a reduction.

The sac, when opened to the view of the operation is incised, and we may be able to see the contents of the hernia, whether it be a loop of intestine or a portion of the omentum.

The intestine, if it is non-adherent, can be reduced with the greatest ease, and even if there exist slight adhesions of the intestine to the sac, these may also be easily liberated and the intestine reduced. But the case is quite different if there are old firm adhesions. In such an event the greatest care must be taken in liberating the intestines from the sac, and especially the peritoneal portion of the omentum if involved. These firm intestinal adhesions are, very fortunately, rarely met with. I can only remember one such in all my experience.

The omentum is nearly always adherent, but its liberation is fortunately far less dangerous than that of the intestines. But when liberated it should be resected and not returned to the abdominal cavity. It is advisable to resect as much of the epiploon or omentum as possible, and to accomplish this the omentum should be pulled gently forward, exposing a portion of the intra-abdominal part. If too little of the omentum is excised, the remaining part will not be well drawn up into the abdomen and this may cause an ultimate return of the trouble. If you reduce the omentum and do not excise any portion of it, the chances of its pressure upon the opening of the inguinal orifice causing a relapse, are very large.

After the omentum has been resected the intestines are reduced, a sponge placed in the inguinal orifice, and the resection of the sac is undertaken. This should also be done as high up as possible.

Nothing further remains to be done but to insert a row of superficial sutures in the skin, and one or two deep ones. I would caution you not to forget the use of a drainage tube, as it is of considerable advantage in obviating any danger of septic infection. The wound is then dressed with iodoform and a bandage applied.

The patient before the class was then etherized and the operation begun, and conducted as described. There were no intestinal adhesions or other complications. The patient made good recovery from the effects of the operation, which lasted but fifteen minutes.

HEMIPLEGIA.

By PROF. CHARLES CARY, M. D.
BUFFALO GENERAL HOSPITAL—MEDICAL CLINIC.

This patient, aged twenty-eight, was brought into the hospital six days ago by the Fitch ambulance, with the history of having been stricken with paralysis on the street. He was found aphasic, with right hemiplegia and facial paralysis. He could feel a pin prick in this side. He could swallow with difficulty, and the tongue could not be protruded. The evacuations of urine and fæces were involuntary.

So far as the previous history is concerned, we can learn nothing. We must determine the anatomical lesions, and the condition resulting, entirely from our own observations. Although the patient can tell us nothing of his condition, you will notice as we go through the examination that he is more or less conscious and capable of understanding us to some extent. His mind has cleared up a little since he first entered, when he was inclined to stupor, but not to such a degree as to constitute coma. When I hold his

nose to force him to open his mouth, you will observe that the movement of the lips is only upon the left side. He shuts his eyes, the left completely, the right only partially; the superior branches of the facial nerve being seldom affected to the degree that the lower ones are. When I ask him to protrude the tongue, he evidently understands me and makes an effort to do it which is partially successful, but the tongue is tilted to the paralyzed side. This is due to paralysis of the hypoglossal nerve. There is no motor nor sensory disturbance of the left side.

The patient's hands are hard and he is evidently a man used to manual labor, but he has not the appearance of having been a drinking man, and he has neither the age nor the build which we usually associate with apoplexy. The right hand is a trifle more puffy than the left, and it has an inactive look. On asking him to hold up his right arm, he tries to respond, and assures me by his expression that he can not do it. There is at present a scaly eruption over the right forearm, and a day or two ago it had quite a papular appearance. This is not at all uncommon in cerebral hæmorrhage, and is due to a trophic disturbance. When I first saw him there was profuse sweating of the entire right side, and attended vaso-motor dilatation. There is no question but that his sensations, if not absolutely normal, are but slightly disturbed in the right side. The mild œdema seen here, and which is often found shortly after paralysis, can be explained in this way. The venous return from the extremities is largely due to muscular contraction. If you should hold your arm in the same position for forty-eight hours the lines would be more or less obliterated on account of a very slight œdema a dropsical effusion all through the muscles, and particularly in the subcutaneous cellular tissue. This is due, therefore, in paralysis, not entirely to vaso-motor disturbances, but perhaps even more to the inactivity of the muscles.

When the patient first came in, tickling his right foot would cause it to be removed. On tickling the right foot now, the response is more in the left foot. The former movement was purely reflex—an involuntary, spinal action of a protective nature. The present reflex has more the nature of a conscious effort to drive away the irritating cause. When there is no sensation, tickling of the foot will usually induce quite complete movement of the leg. There is now a certain resistance as I move the paralyzed leg; and this is not uncommon in recent paralysis. It is of the same reflex nature as the attempted withdrawal from the finger on tickling the foot. The patellar reflex is usually rather exaggerated after paralysis, but here it is apparently much reduced. The reflex, however, is equally slight on the normal side.

When the patient was first brought in, his breathing and heart-action were very slow, the slowness being undoubtedly due to the shock he had received at the time of the vascular rupture. The first sound of the heart is normal, sharp possibly, and a trifle prolonged, but without murmur. With the second sound, there is a dragging murmur, not a bellows murmur in any sense, but almost such a sound as you would get from dragging the foot over the floor. I do not know but that it is an uncertain and irregular closing of the aortic valves. It seems a little too distant to be a friction sound. I am not inclined to consider it a regurgitant murmur, for if the patient had had a long continued aortic insufficiency, he would have quite a degree of cardiac hypertrophy or dilation which is not indicated by the point of the apex impulse nor by the area of cardiac dullness. Acknowledging at the outset that the determination of this man's cardiac lesion has not been effected, I wish to wait before stating how far the cerebral lesion depends upon that in the heart. I am inclined to think that he has had a minute aneurism of one of the cerebral arteries, and I take this view because this is the most common cause of cerebral hæmorrhage. I imagine that during some temporary excitement or exertion the force of the heart ruptured this aneurism and poured out a mass of blood which caused the paralysis.

As to the location of the rupture, all evidence places it upon the left side of the brain, either in the cortex or more probably in the neighborhood of the lateral ventricle, that being the locality where the vessels are most numerous and where rupture most commonly occurs. The amount of blood poured out, we cannot determine; sometimes a small clot will produce all the symptoms which we note here, and again a large clot may occasion comparatively slight results.

As to the outcome, I should expect this man to improve and rather rapidly, but I question very much whether he will recover completely for the reason that the arterial disease, the arteritis, which is the probable cause of this aneurism which, we have supposed, has ruptured, makes it probable that under similar circumstances of increased excitement or exertion and consequently heightened arterial tension, and particularly as

age advances, rupture may again occur, not necessarily in the same place, but in some other part of the brain.

The patient has presented no symptoms requiring immediate relief. In any case of paralysis, attention must be given to the condition of the bladder and the bowels so as not to allow retention of urine and fæces. This man has incontinence and not retention. If he had a high bounding pulse with great hypertrophy of the heart, I should have thought blood-letting of service. This, however, is rarely resorted to of late years. Five or six years ago, I bled a man and to the best of my knowledge the operation has not been done in this hospital since. This case I saw very early, the arterial tension was high and I believed the hæmorrhage in the brain to be still in progress. Elevation of the head, cold applications to the head and stimulation of the bowels to draw blood from the upper portion of the trunk and head, would in most cases be about as effective as venesection. I prefer saline cathartics, but it is the custom with many to use a more irritating cathartic, such as croton oil. For the time being, this patient is simply being watched and he is recovering, as such patients generally do unless they die from the first shock, which is not an uncommon thing. In the course of the next five or six days, we shall institute a plan of treatment which will, perhaps, render some relief. I say *perhaps* for the action of our remedies, especially in cases of hemiplegia, is not always satisfactory. I shall put him upon potassium iodide for several reasons. In the first place, because the alkali which it contains is rather good to reduce arterial tension; the iodine promotes absorption as much as any agent that can be used for that purpose, and the blood clot in this patient's brain can be removed only in this way. Again, the cause of miliary aneurism is very commonly endarteritis of syphilitic origin. It would be difficult for me to suggest why a man of this age, with such apparently good health, should have cerebral aneurism even of small size except as the result of syphilis. Do not think of miliary aneurisms as being as big as beans or peas even. They are extremely minute dilatations of small arterioles. This man has been carefully examined for syphilitic markings without finding any. Miliary aneurisms, however, are often due to the rheumatic taint and potassium iodide is as good for a suppressed form of rheumatism as any remedy that can be used. After a few days, in order to prevent degeneration of the muscles, we will undertake massage and passive motion of all the joints, and especially making complete extension, for even now I notice that the flexor muscles are beginning to gain the ascendency over the extensors, and if a contracture once occurs it can never be fully overcome.

COMMUNICATIONS.

A DISCUSSION ON PHAGOCYTOSIS AND IMMUNITY *

At the Pathological Society of London, March 1st, 1892.

The discussion on Phagocytosis and Immunity, which was adjourned from the last meeting, was resumed (Sir GEORGE MURRAY HUMPHRY, F.R.S., President in the chair) by

V.—J. SYER BRISTOWE, M. D., F. R. S.,

Senior Physician and Joint Lecturer on Medicine in St. Thomas's Hospital.

Dr. Bristowe approached the subject from a clinical point of view; he showed that the resistance of the body to the invasion of infective diseases was provided for in various ways: (*a*) mechanical, as the opposition of the skin and mucous membranes; (*b*) by inflammation with subsequent encapsulization or suppuration; (*c*) by active warfare or phagocytosis; (*d*) by unfitness of soil, etc. With regard to (*c*), he agreed with Dr. Burdon Sanderson's position as stated at the last meeting. Should the infective principle succeed in getting past these first barriers, they would enter the system along the blood vessels, or more commonly along the lymphatics as far as the first group of glands. He thought that cure occurred by the infective principle getting beaten at the mucous membrane or at the lymphatic glands; but these modes of spontaneous cure would not include the cure of the exanthemata after their generalization; and it was in these cases especially that immunity most frequently arose.

He then contrasted various types of infectious diseases, taking tubercle, diphtheria, and typhoid and small-pox as types of the different varieties. Local skin tubercle or lupus, instead of producing general tuberculosis, seemed to prevent it. In diphtheria and typhoid the chief symptoms were associated with the local lesions rather than with the generalized poison, which as a rule produced its effects after the subsidence of the local lesions. With small-pox and the other exanthemata the conditions were wholly different. Taking

*Continued from last issue of the REPORTER.

inoculated small-pox as an example, the poison appeared to be developed for nine days, with formation of the pustule and enlargement of neighboring glands; then the generalized condition set in, with eruption on the third day. Immunity seemed to be acquired in the earlier stage of the disease, as it was remarkable that whilst the pocks were developing the poison from them was not absorbed by the body. Probably the pocks were really cut off from communication with the rest of the body by phagocytosis and by the inflammation which surrounded them. By vaccination the generalized disease that was produced and which gave immunity was comparable to the invasion period of small-pox, but he could not say how the immunity was caused. He suggested that it might be possible to avoid the local ill effects of vaccination by injecting the lymph deeply into the tissues or into the glands.

VI.—WM. HUNTER, M.D., M.R.C.P., F.R.S.E.,

Assistant-Physician to the London Fever Hospital; Research Scholar to the Grocer's Company.

PART I.—RELATING TO IMMUNITY.

Before discussing the probability of one or other doctrine, it is well to have the facts clearly before our minds. The facts, then—to take the simplest case—are briefly these: that in non-protected animals virulent bacteria inoculated subcutaneously produce little or no local change, grow unhindered, and cause general infection; while in protected animals inoculation of the same bacteria is followed by a local leucocytosis at the point of injection, a certain degree of inflammation is set up, and general infection is prevented.

In virtue of some change in the body, that which was formerly capable of setting up a general disease can now only set up a local affection. What is the nature of this change? On the one hand, we have the bacteria with their powers of forming poisons undoubtedly capable in many instances of affecting the organism most injuriously. These poisons are of two kinds: (1) easily diffusible substances of alkaloidal nature—toxines—whose mode of action on the organism is analogous to that of the vegetable alkaloids; and (2) less diffusible substances of proteid nature, whose nature is still very imperfectly known. So far as is known, however, their action resembles more that of ferments than of ordinary chemical poisons, inasmuch as it is lost on heating to a temperature of 50° or 60° C., at which the active properties of ferments are generally destroyed. Both these classes of poisons stand in the same relation to the bacteria, in so far as they are the special products of their activity, in the same way that nitrogenous products, such as urea, or active proteid substances, such as ptyalin or pepsin, are the products of the activity of cells of higher organisms.

In addition to these two groups of metabolic products formed by bacteria, there is another class, differing both in origin and action from the foregoing. These are also proteid bodies, having, so far as is known, the character of albumoses. These are substances—first described by Nencki in 1880—derived from the bodies of the bacteria themselves, so-called "proteins," for a knowledge of whose action we are indebted, perhaps, most of all to Buchner. They resist in a remarkable way the action of heat, withstanding when in a moist condition even boiling temperatures. Their most remarkable property, however, is their chemiotactic power, the power of attracting wandering cells, and inducing, therefore, a greater or less degree of leucocytosis wherever they happen to be present. Their action in this respect I hope to illustrate to you later on.

It is to be noted as a further difference between these two classes of bacterial products, the toxines and toxalbumens, on the one hand, and the proteins on the other, that the former are only formed, and are formed most abundantly when the bacteria are active, the latter only, and most abundantly, when the bacteria are dying.

A further difference—an important physiological one—may be noted, namely, that while the former are responsible for the general symptoms of disease, the action of the latter is, in the first instance at least, mainly a local one. Without being entirely confined to the part where they are formed, the most important action of these proteins, and the one which lends them their chief interest, is the chemiotactic power above mentioned.

When we turn now from the invading bacteria to the organism thus attacked, we find that the means it has at hand to defend itself are of a two-fold character. On the one hand, there are the cells—especially those free lances of the body, the wandering leucocytes—having the power of seizing upon everything, animate or inanimate, possessing a less power of resistance than themselves, and, in virtue of this power, doing undoubtedly much useful work for the organism both in health and disease. The theory of phagocytosis, so beautifully and skilfully elaborated by Metschnikoff, in the first instance, assumes, on the basis of many observations whose accuracy cannot be seriously

called in question, that this power is exercised in a special degree by the cells in defending or protecting the organism against bacteria.

This is admittedly, however, not the only weapon possessed by the body in its defense. Apart altogether from the action of living cells, the plasma and serum of the blood is now known, through a series of equally beautiful researches, to possess, under certain circumstances, antibiotic properties when withdrawn from the body, bacteria being killed after a short exposure to their action.

It has been shown, moreover, for certain bacteria (for example, vibrio Metschnikovi, by Behring, and Nissen) that the power which the body possesses of resisting their action is proportional to the antibiotic properties of its blood serum, the serum of animals rendered immune having strong bacteria-killing power, while that of the ordinary animal favors the growth of the bacteria. This then is the basis of the view opposed to the phagocyte doctrine, of the so-called humoral doctrine. It is assumed by the upholders of this view that the protecting power possessed by the body is really due to these antibiotic properties of blood serum to the action of the fluids of the body rather than of the cells.

Unfortunately for this view which, in presence of such facts as those above referred to, seems a reasonable, not to say a seductive, one, it is admitted that this relation between degree of protection possessed by the body and the antibiotic properties of its blood serum is not only not a constant, but that in certain cases it is completely reversed, and that the serum of an animal very sensitive to the attack of certain bacteria, when these are injected into the body, may be nevertheless extremely bactericidal in its action on these bacteria when tested outside the body. Thus it has been shown by Roux and Metschnikoff that the serum of young rats sensitive to anthrax has a bactericidal action on anthrax bacilli outside the body; and by Lubarsch that the extravascular blood of a rabbit can kill millions of anthrax bacilli, while a few of these injected into the blood suffice to kill the animal.

It is clear, then, that some caution is necessary in deducing from the action of blood plasma and blood serum after it is withdrawn from the body what its action within the body is likely to be. So far as the evidence at present goes, there is no established relation between the two.

As regards the nature of the substance or substances in plasma or serum to which this bactericidal action is due, little is known further than that they are proteids. In one case the substance was found to have the characters of globulin (Hankin); but with this exception—and the observation is an isolated one—but little progress has yet been made in identifying these substances with any special class of proteids. The most recent work renders it to my mind exceedingly probable that it is not to any one definitely characterizable proteid substance that this bactericidal property of serum is due, but rather to some special association, of an altogether more complex character, of one or more proteids.

The recent work of Dr. Wright, on which I trust we may hear something from him in this discussion, appears to me to have a special interest in this relation, and a very direct bearing on this point.

He has shown that the "tissue fibrinogen" to which Wooldridge ascribed such an important *rôle* in coagulation phenomena, and which he found also to be capable of conferring a certain degree of protection against anthrax, is, in all probability, a double proteid body, one of albumose nature and the other a nuclein substance.

PART II.—INTERPRETATION OF THESE FACTS.

So much, then, for the facts on which, as Professor Sanderson has said, we are for the most part agreed, and so much incidentally for certain of the difficulties that arise in interpreting aright their significance. If we now consider the application of these facts to the phenomena of acquired immunity, as above described, we find that the divergences of opinion which exist amongst bacteriologists relate more to the order of occurrence and relative importance of the events than to the events themselves.

The two chief events are that a short time after the inoculation of virulent bacteria into an immune animal a large number of leucocytes are found at the seat of inoculation, and a large number of the bacteria are found lying enclosed within these leucocytes and other adjacent cells.

According to the doctrine of phagocytosis, the leucocytes have been attracted thitherwards by the chemiotactic action of certain of the products of bacterial action; that they then act as phagocytes, and engulf the bacteria. It is not denied that in "reacting" to the presence of these products they may likewise produce substances capable of acting on the bacteria injuriously without the latter being taken up. It is nevertheless maintained that the intracellular method is the chief method employed in injuring the bac-

teria. The protein substances given off by the dying bacteria exert further chemiotactic action, and attract more leucocytes, till finally, at the seat of attack, is mobilized a regular army of agents capable of resisting successfully all further invasion.

The opponents of this view maintain that the first event is not an attraction of leucocytes, but a death of certain of the bacteria brought about through the agency of bactericidal substances present in the serum, and that the leucocytosis is secondarily induced by the proteins set free from the injured bacteria. The subsequent inclusion of the bacteria within these cells is an event of altogether secondary importance. The cells in taking up the bacteria exercise merely their ordinary scavenging function, and not any special phagocytic function.

The question at issue between the two opposing schools of "phagocytists" and "humoralists," as will be seen, is thus one that lends itself readily to active discussion and controversy, for the differences between them are those of degree rather than of kind.

The phagocytists assert that their opponents attach too much importance to the bactericidal action of blood serum, and too little to the cells; while the latter report that the so-called phagocytic function is a purely scavenging function, and that the chief factor in inducing the leucocytosis is the production of proteins from the already dying bacteria.

In the words of Buchner, the chief exponent of the humoral theory, the essential active processes underlying immunity can only be of chemical nature. According to this theory it is a fatal error to assume that in protected animals the bacteria find themselves precisely the same conditions, before leucocytosis sets in as in non-protected animals. According to the doctrine of phagocytosis, it is the special reaction of cell protoplasm that determines the issue, the action of chemical products being of secondary importance. A certain antagonism there undoubtedly therefore is between the two views; but the doctrines are not in my opinion so opposed to each other as to be mutually destructive.

I gather from the course the discussion has so far taken that some misapprehension seems to exist on this point. It is assumed that there is an inherent antagonism between the two views, and that to establish the one it is only necessary to show up the weakness of the other. Acting on this assumption, the speakers so far have confined themselves mainly to pointing out in how far the doctrine of phagocytosis falls short of perfection. The result has been to show that in their opinion it falls very far short indeed of that point; for we have heard that not only is it imperfect, as we all admit, but that it is utterly opposed to general biological principles; much of it untrue; what of it is true is not new: it is illogical, mechanical, in fact altogether unsatisfactory. Having made out this case to their own satisfaction, the speakers quietly assume that they have firmly established the immense superiority of the opposing view.

Their practice appears to be based on one, if report speaks true, not altogether unknown at the bar, which consists in supporting a case itself weak, by exposing the weak points of the one opposed to them. In the present instance it takes the form of abusing the doctrine of phagocytosis, and letting judgment go by default in favor of the "humoral" doctrine. They have unconsciously accepted a brief for the latter doctrine, and have done their best for their client by abusing the opposing one.

Like many other arguments that in the first instance appear very strong those adduced against the correctness of the doctrine of phagocytosis lose in my opinion much of their weight on being carefully looked into. I feel myself freer to express this opinion because I am not at present appearing on behalf of that view, but have accepted a "watching brief" on behalf of a client of my own; an intervening client whose interests and reputation appear to me not unlikely to suffer in the action thus raised against the doctrine of phagocytosis.

Exercising my right, I do not choose to divulge this client's name.

Objections to the Doctrine of Phagocytosis.—The objections raised in this discussion against the doctrine of phagocytosis group themselves into two divisions: (1) General, those which impugn the inherent probability of the doctrine charge it with being mechanical, illogical, opposed to biological principles; and (2) special, those which dispute the accuracy of the data on which it is based.

1. *General Objections.*—With regard to the more general objections, it is extraordinary how much opposition has been called forth by this doctrine, and how much warmth of feeling has been imported into its discussion by the parties on both sides. It is little wonder that outside witnesses of the controversy should conclude that some deep underlying principle must be at stake, and that the two views must be utterly opposed to each other.

What then are the principles involved? On the one hand it is asserted by the upholders of the doctrine of phagocytosis that living cells have the power, under certain circumstances, of taking up living bacterial organisms; of acting on them in such a way as first to kill them and then completely destroy them.

In other words, it is asserted that one form of living protoplasm has the power of taking up within itself another and presumably weaker form and destroying it altogether. If any biological principle is more firmly established than another, it is surely that such a power is possessed by protoplasm. It is maintained, further, that this is the chief way in which the body protects itself against attacks of infectious disease, and that the difference between one who has had an attack of an infectious disease—for example, scarlet fever—and has thereby acquired protection, and one not so protected, is that in the former the individual cells have acquired some additional property, which enables them to resist successfully from the beginning where previously they had only been able to do so after the disease had run a certain course.

As thus put, the doctrine seems to lay itself open to the charges brought against it; that it does not add much to what we previously knew; that it only expresses in terms of the cell what we have long been in the habit of stating equally clearly in terms of the body as a whole; moreover, that it brings no new properties of the cell to light, for that we have long known that the cells had a sort of scavenging function, and were in the habit of taking up, so to speak, whatever they could lay hold of.

Further, as Dr. Klein would maintain, it is not proved that the bacteria find themselves so uncomfortable with the body as is generally supposed; that possibly the cells, so far from enjoying their repast of microorganisms, suffer as often as not from surfeit, and themselves die, victims of their own voracity. In short, the doctrine is in great part not new, true, nor logical.

In reply to these various objections it may be urged with some force that, even if it had only directed our attention from the body as a whole to processes going on in the individual cells of that body, an important step would, in my opinion, have been taken—a step in the direction in which all advance in pathology has been, and is destined to be, made—namely, from the general to the special. The history of pathology is a history of such advance, from the spirits which formerly caused disease, independent of the body, to the body itself; from the body as a whole, with its vapors and humors to the particular organs involved; from the organs to the special cell structures implicated; from these in turn to the nature of the disturbing cause. Further, that while it is not claimed that any new property of cell protoplasm has been discovered, the observations on which the doctrine of phagocytosis is based are an important extension of our knowledge of cell function in an entirely new direction. It is the application of the teachings of cellular pathology to the phenomena of infectious disease and immunity from that disease, and to that extent it can fairly lay claim to have added something new to our knowledge.

As to Dr. Klein's demonstration of the phagocytic process in leprosy and other chronic diseases, and his contention that it can, therefore, have nothing to do with immunity, I venture to submit that that contention is altogether beside the mark, for it is not asserted that phagocytosis and immunity are synonymous terms, and the contention fails altogether to take note of the difference between an acute infectious disease and one running a slow course such as leprosy. The upholders of the doctrine of phagocytosis cannot be held responsible for these differences; they are only concerned, so far as they can, to explain them. And when we endeavor to do this, we find that not only does the above contention fall altogether to the ground as an argument against the relation of phagocytosis to immunity, but it lends, in my opinion, strong support to that view; for chronicity of an infectious disease like leprosy or tuberculosis can only be due to one or other, or both, of two causes —relative weakness and harmlessness of the attacking microbe, that enables it to maintain a precarious existence by not exciting any particular disturbance, or only a local disturbance; or, secondly, presuming the microbe to be fairly strong, great and prolonged resistance carried on on the part of the body for a term of years.

In warfare, next to a complete defeat of the enemy, that which speaks most for the efficiency of a force is its power of carrying on a protracted struggle against superior forces. And so likewise in infectious disease. Next to successful resistance once for all to a disease as in measles or scarlet fever, that which speaks most for the resisting power of the body is chronicity of the disease itself. When, therefore, Dr. Klein points to phagocytes crammed with bacilli in leprosy, he points to facts that, so far from upsetting the doctrine of phagocytosis, lend strong support

to it, for chronicity of an infectious disease I would define as a relative immunity. His argument would have had weight against the phagocyte doctrine if he had been able to point to leprosy or other chronic infectious disease, and demonstrate that no bacilli were to be found in cells, and yet the body had been able to carry on its struggle for many years. As the facts stand, any force his argument has is in favor of the phagocyte doctrine.

And when we come to the question of logic, which position is the more logical—that which ascribes to cell protoplasm and direct cell action, as the doctrine of phagocytosis does, or that which ascribes to certain products of that activity acting at a distance from the cell, as the opponents of that view maintain, the power of combating and ultimately destroying pathogenic micro-organisms, I confess for my own part I have little hesitation in giving my opinion.

And it is this that the view which ascribes to products of cell action present within serum or plasma the property of being able successfully to wound, maim, and render harmless invading bacteria, and yet denies to the protoplasm of the cells which produce them the slightest power of controlling or in any way influencing the growth or virulence of bacteria. Such a view, I submit, is as utterly illogical as any could well be.

On grounds of logic I give decidedly the preference to the view which subordinates the product to the cell which produces it, and hence if I have to choose between the phagocyte theory which exalts the direct action of the cell without ignoring its more indirect action and the humoral theory which exalts to a pinnacle the action of bactericidal substances admittedly produced by cells, while denying to these same cells any special bactericidal action, I give my decision unhesitatingly for the doctrine of phagocytosis.

2. *Special Objections.*—The above does not constitute, however, the head and front of the offending of this doctrine in the eyes of its opponents. That which above all appears to them as gratuitous foolishness in it is, I take it, that it not only ascribes to cells, but to certain particular cells, this special phagocytic function. It is this pretentious claim on behalf of the leucocyte and lymphocyte that rouses the special scorn and indignation of the humoralists; and they express a contempt for these little structures that, could they but feel it, would cause them to shrivel up with shame at their own want of modesty and general aggressiveness of conduct towards bacteria.

Curiously enough, it is this special claim of the phagocyte theory, when considered in relation with the facts on which the humoral theory is based, that commends it specially to my acceptance, and strengthens its otherwise inherent probability—the inherent probability of the view, namely for which it contends, that the duty of defending the body against the attacks of infectious disease is not distributed amongst the cells of the body as a whole, but is relegated to certain special cells. These are arranged so as to constitute what has been termed two lines of defence. The first line of defence is formed by the leucocytes of the blood; the second by the lymphocytes and of follicular tissue generally, chiefly that of spleen. The former bear the first brunt of the attack at the seat of inoculation, the latter act as reserve forces. It is these cells on whose behalf I consider myself "retained."

According, then, to the doctrine of phagocytosis, acquired immunity is due to an altered habit of body on the part of these cells, transmissible from generation to generation. Its opponents, scorning such a view as visionary and unsatisfactory in the extreme, and based on insufficient data, prefer to refer it instead to a change in the character of the fluids of the body. This latter view implies an altered constitution on the part of the plasma and serum of the blood, without even suggesting in what way such an alteration has been brought about, except through the agency of cells.

Moreover, this alteration is one that in certain cases presumably lasts for years, and hence one of two conclusions follows: either that, once produced, it remains permanent—that blood plasma can transmit its characters without the intervention of cells; or that the change is one constantly being carried out by the cells of the body, The former, I need hardly say, is a wild hypothesis having no support either in facts or analogy; and therefore we must accept the alternative conclusion that, *even on the humoral theory of the nature of immunity, the essential change is an alteration in the cells, such as the doctrine of phagocytosis contemplates.*

This, however, it may be urged, does not carry us very far forward. We knew before, as Professor Sanderson has already pointed out, that the body possessed what he has termed a specific power of resistance to disease; and this *vis medicatrix naturæ* is naturally derived from its cells, if not resident in them.

The final teaching of the doctrine of phagocytosis would thus appear, as Mr. Kanthack

pointed out, to resolve itself into this: that what we formerly in our ignorance referred to the organism as a whole, we now refer to the individual cells of that organism. I have already replied to this objection so far as it applies to the cells of the body as a whole; I have now to submit that in going further, and referring to certain particular cells of leucocyte and lymphoid nature, a special *rôle* in combating infectious disease and in conferring immunity, the doctrine of phagocytosis is not only an advance, but constitutes, in my opinion, a great advance in our knowledge of the mechanism and nature of immunity.

I base this belief on grounds independent altogether of bacteriological studies—on data derived from my study of the physiology and pathology of the blood—and I will now endeavor to make these grounds clear.

The changes relied on by the opponents of the phagocytic doctrine of immunity affect in a special degree, if, indeed, not exclusively, the plasma and serum of the blood, and are to be referred to antecedent changes in the cells of the body as a whole, rather than in any particular group of cells.

In this view I recognize a great resemblance to one still widely held by both physiologists and pathologists regarding the constitution of the blood and blood plasma—namely, that the composition of the blood at any time is determined by the united action of all the tissues of the body.

As I had occasion to point out in the Arris and Gale Lectures of 1889, such a view is not supported by facts; the facts, on the contrary, point to a certain class of cells grouped for the most part in relation to a particular portion of the circulation as being primarily, if not exclusively, concerned with the constitution of the blood plasma—whether in building it up or in effecting alterations in it.

These cells are the leucocytes of the blood and the mass of lymphocytes lying in relation to the portal tract, especially those of spleen and alimentary tract.

It is a coincidence to which I am inclined to attach not a little importance that the class of cells thus found to be mainly responsible for the constitution of the plasma is precisely the same group of cells found by the upholders of the doctrine of phagocytosis to possess phagocytic properties in a specially marked degree, and that the chief seats of phagocytic action outside the circulation itself are, as is agreed to by all, in the first place the spleen, and, as has been clearly shown by Ruffer, in the second place the alimentary tract.

Action of Spleen in Relation to the Blood and to Infectious Diseases:—It is not my intention to adduce here or now the evidence on which the above conclusion is based, so far, at least, as the leucocytes generally and the lymphoid cells of the gastro-intestinal tract are concerned. Suffice to say that I have always found changes in the constitution of the plasma associated with evidences of great activity on the part of these cells—nuclear division, increased fragmentation, and formation of granular *débris*. And as to the important part taken by these cells as phagocytes, I leave to others who afterwards speak in this discussion. In the hands of Dr. Ruffer and others, I have no doubt ample justice will be done to that *rôle*.

For myself I propose to confine my attention solely to the spleen, and endeavor to establish the justice of the claim made on its behalf by the doctrine of phagocytosis, that its cells have a special phagocytic function independent altogether of the scavenging function common to them and other active cells. In particular I hope to show that they have what is claimed for them and to a less degree for the leucocytes by the phagocyte doctrine a greater selective power than other cells of the body, and that this selective power is specially exercised by them in relation to causes tending to affect the constitution of the blood plasma.

The observations I am now about to refer to date from 1887. They were not made with any reference to their bearing on the doctrine of phagocytosis—a circumstance that should, in my opinion, enhance any value that may attach to them in this relation.

The evidence I would adduce from them relates to the action of poison on the blood (1) in the presence and (2) in the absence of the spleen. Briefly stated, it goes to show that the power possessed by certain drugs of altering the constitution of the blood depends primarily on the action of the splenic cells, and not on the cells of the body generally.

My experiments show for the poison toluylendiamin that its well-known destructive action on the blood is in an altogether special degree dependent upon the presence of the spleen; and that in the absence of that organ animals (rabbits) can tolerate about twice the dose without the slightest effect that would otherwise suffice to produce recognizable changes in the blood.

This difference in the action of poisons on the blood when the spleen is present and when it is absent does not apply to substances whose action on the blood is mainly phy-

sical, such as distilled water or glycerine, or, although to slightly less degree, pyrogallic acid. Nor is the power thus possessed by the spleen in the case of certain poisons due to any scavenging function on its part—the presence of a greater quantity proportionately of the substance in the spleen than elsewhere. On the contrary, by a method that enabled me to recognize the presence of even one-hundredth part of a milligramme of the above poison, and whose margin of fallacy I found to be by accurate control to be less than ½ per cent., I was able to show that the amount present in the spleen was less than in any organ of the body and less than that in the blood.

The result I interpret as showing what indeed other observations clearly satisfied me was the case that its injurious action on the blood was not a direct one, but an indirect one due to the intermediate action of certain cells, notably those of the spleen.

The bearing which these observations have on the subject now under discussion, the *rôle*, namely, of the cells of the spleen in modifying the constitution of the plasma of the the blood will, I trust, be obvious. For the subject of immunity and phagocytosis in relation to immunity involves a consideration not only of the action of cells on microbes, but also of the action of the cells on the products of these microbes. And these experiments appear to me clearly to establish that as regards these products, whose action can in no case be considered a purely physical one, their action on the plasma of the blood, for good or ill, must in a very special degree be dependent on the action of the splenic cells —of cells, which are claimed by the doctrine of phagocytosis to possess this phagocytic power in a special degree. *They clearly show at least for the products what the doctrine claims to be the case for the microbes themselves, that the splenic cells possess a special selective power that must render their action of the very greatest importance in the struggle against infectious disease.* And we are not without more direct evidence that such is the case. A series of experiments have recently (1889) been published, by Bardach, showing that the absence of the spleen affects materially the chances of recovery from infectious disease. His experiments were made on dogs, which are not naturally susceptible to anthrax even when inoculated subcutaneously; when it is injected into the blood they also resist, although a certain number succumb. After removal of the spleen they become much more susceptible. Thus out of twenty-five dogs whose spleens were removed, no fewer than nineteen died, while out of the same number of normal dogs similarly inoculated with anthrax only five died.

On the humoral theory of the nature of immunity it is difficult to understand how the absence of the small quantity of serum —to whose antitoxic and antibiotic properties recovery in such cases is ascribed—presumably present in the spleen could make a difference of such vital importance. Moreover, it is not easy to reconcile these facts with Dr. Klein's contention that even when phagocytes are present it is as probable that the microbes find themselves as comfortable within the cells as outside of them. If such were the case, the spleen ought really to be a favorable seat for the growth and multiplication of bacilli rather than the converse; and its removal should rather increase than diminish the animal's chance of recovery.

It must not be supposed for a moment as tending to weaken the force of this argument that the animal after the removal of its spleen is in an unhealthy state. On the contrary, except in respects of its power of resistance to the action of poisons and microbes, it appears to be in no way affected by the operation, as I have constantly had occasion in the course of my experiments to observe.

Time will not permit me to touch, as I should have liked, on the subject of chemiotaxis and its relation to phagocytosis and immunity. What I should have said I may compress into the few remarks that I may make in demonstration to you, as I now propose to do by means of lantern slides the chemiotactic properties of certain of the tox-albumoses I have isolated from tuberculin. The method employed to study the action of these substances was the one of which you will hear more from Dr. Ruffer, whose method it is. To Dr. Ruffer I am indebted for his great kindness in himself making the first obsevations with these substances for me; and I gladly take this opportunity of thanking him.

CONCLUSIONS.

In conclusion, I would formulate in a few words the chief grounds on which I think the doctrine of phagocytosis claims from us a greater credence than the one which has been opposed to it. I am disposed to claim for it that in revealing to us as it has done for the first time the potentiality possessed by cells of themselves combating the attacks of virulent microbes, it has added much that is not only new, but it is also valuable and important regarding the means by which infectious diseases are combated, and that our

knowledge of the bactericidal properties of blood serum, to which so much importance is attached by the opponents of the phagocyte doctrine, is itself the direct outcome of the attention drawn by Metschnikoff to the action of cells.

So far from being antagonistic, the two doctrines—the phagocytic and the humoral—mutually supplement and support each other; disproof of the phagocytic theory, so far from proving the correctness of the humoral, tends, in my opinion, to weaken it. Both theories recognize the existence of antitoxic and antibiotic substances of blood serum and blood plasma; but it is, in my opinion, the peculiar merit of the phagocytic as opposed to the humoral doctrine that it subordinates them in interest and importance to action of the cells from which they admittedly derive their origin. If a choice has to be made between the two views, the one we can least do without is that which attaches a preponderating importance to the cells of the body than to the fluids, to the action of the cells rather than to the products of that action, to the agents rather than to the instruments.

I am disposed to claim for the phagocytic theory that, while it does not profess, as its opponents allege, to be in any way a complete or satisfactory explanation of the phenomena of immunity, as a working hypothesis—and it is that we must first look for—it is in all respects more logical, more tenable, more in consonance with the teachings of cellular pathology, and I would almost say more biological than that which ascribes to the fluids of the body the first *rôle* in protecting it against infectious disease.

Considered apart from the teachings of phagocytosis—as the supporters of the humoral doctrine appear always desirous of doing—the humoral doctrine has as its chief characteristic, in my opinion, a self-satisfying sufficiency for which there is no real basis. It appears to explain, without explaining. It speaks much of antibiotic and antitoxic substances in body fluids, and is apparently content to rest there; it does not ignore their origin from cells, indeed cannot possibly do so; but, unlike the doctrine of phagocytosis, it does not encourage further inquiry into the nature of the changes of cells which lead to their production, into the conditions which determine the precise "reaction" in the cells necessary for their formation in the first instance.

On both views the final nature of the change, whether in cell or in product, is unknown; but as the change in the cell must necessarily precede that in the product, and the doctrine of phagocytosis directs most attention to the cells, that doctrine has in my opinion claims on our support out of proportion greater than any teaching that would even temporarily draw our attention away from the cell to the fluid in which it lies, that would exalt the product at the expense of the producer.

Lastly, I claim for the phagocyte doctrine that in attaching special importance to the action of certain cells—leucocytes of blood, cells of spleen, and lymphocytes generally—it draws attention to facts of wide physiological importance, namely, that it is precisely these cells that govern, in a special degree, the constitution of the plasma and blood serum. Whether acquired immunity be due to a direct phagocytic action of these cells, or to antibiotic or antitoxic properties of the plasma of the blood, the preceding changes must affect in a special degree these cells.

VII.—SIDNEY MARTIN, M. D.,

Assistant-Physician, University College Hospital.

Dr. Sidney Martin said that the question might be studied in two directions: (1) as to what rendered an animal naturally immune to a disease, and (2) as to the mode of production of experimental immunity. Immunity produced by experiment was a much better method of research than the investigation of natural immunity, inasmuch as the conditions of experiment were controllable.

Of the several examples of experimental immunity now known, that of anthrax was perhaps the best to be discussed, as the morphology of the bacillus anthracis was so well known.

In the classical experiments of Pasteur the attenuated bacillus anthracis when inoculated into a sheep was found to produce some digree of illness, which passed off. The animal was rendered immune, as the inoculation of a virulent bacillus one month after vaccination failed to produce death. What they wished to know was what happened to the virulent bacilli injected; why did they not kill the sheep as they did in an unprotected animal? Those who depended on phagocytosis for an explanation would say that the action depended on the activity of the leucocytes at the seat of the inoculation of the virulent bacilli, and that these leucocytes effected the destruction of the bacilli. This explanation was, to his mind, by no means sufficient. They had in the experiment just quoted first the injection of an attenuated living virus, and then

a subsequent inoculation with a virulent virus, also living. Now, as he had shown in his last paper in the Report of the Medical Officer of the Local Government Board (1890–1891), the attenuated anthrax bacilli formed the same chemical products as the virulent bacilli; but that whereas the attenuated bacilli would grow well for a time in a culture medium (such as alkali-albumen broth) in which they could form the products, after a certain period they stopped growing; the virulent bacilli would, in a similar solution, go on growing for a much longer time, and would produce a much larger quantity of chemical products than the attenuated. A bacillus, whether attenuated or virulent, acted by means of its chemical products. In the case, therefore, of Pasteur's sheep experiment, it must be said that immunity was produced by means of the chemical products of the attenuated bacilli, and yet the virulent bacillus which produce the same products did not kill the animal. Its natural growth and activity had been inhibited. How could this be explained? Part of the explanation appeared to be that the inoculation of the attenuated virus accustomed the animal to the specific chemical poison of the bacillus. Several instances of tolerance of drugs, such as morphine and arsenic, were well known in pharmacology—a tolerance which, when established, would enable the person to take with impunity a dose of the drug which would be fatal to an unprotected person in a few hours.

A certain degree of tolerance to virulent anthrax bacilli might be established in animals by means of the chemical products of the micro-organisms, as in the following experiments quoted:

A guinea-pig was inoculated under the skin of the right thigh with 10 milligrammes of the anthrax albumose and 9 milligrammes of the alkaloid; under the skin of the left thigh, with a "mash" of the spleen of an animal which died of virulent anthrax. This dose of the chemical products produces only a slight physiological effect in guinea-pigs. The animal lived four days and a half, whereas the control animal died within twenty-four hours. The lesions found were those of anthrax. In a second guinea-pig, done at the same time, the same dose of chemical products and of "splenic mash" were mixed together and injected under the skin of one thigh. This animal showed no change for twenty days, when it died somewhat suddenly. A *post-mortem* examination showed no œdema at the site of inoculation, and only a slight enlargement of the spleen, which was very pale.

In the first experiment, he should say that part of the explanation of the delay of death was that the chemical poisons influenced the organs (of the central nervous system) which they selected for their action, and that the effect of this action was to prepare them for the onset of the larger amount of products produced by the virulent bacillus, but that the alteration in the tissues was too slight to prevent death. Such an experiment was a very imperfect imitation of what occurred after the inoculation of an attenuated living virus, for he thought that the products of the attenuated bacillus, being gradually formed, were gradually absorbed, so that the physiological effect was one of repeated small doses of the specific poison, the action lasting for a long period of time. That the chemical products of pathogenic bacteria were a long time in the body he knew from his own experiments. A single dose of the anthrax albumose would produce fever lasting five days, and with the products from other diseases he found evidence of their presence in the blood ten, or even twenty-four days after inoculation. It was probable, therefore, that the chemical products of attenuated bacilli would remain longer in the body than when the chemical products were simply injected, and he had but little doubt that this retention of specific chemical substances in the blood (which they profoundly affected) had an important bearing on immunity.

Why, it might, however, be asked, did not the virulent bacillus grow in the artificially immune animal? Even supposing the chemical products of the attenuated virus were present in the body at the time of inoculation with the virulent bacilli, could they be supposed to stop the growth of the bacilli, or weaken them so that they behaved like the attenuated virus in having a short existence? The second experiment appeared to bear on this point, for mixing the chemical products with the bacilli delayed death for twenty days, while in the first experiment, where the injection occurred once on each side of the body, death was delayed for only fourteen days and a half. Now, if virulent bacilli were grown in a flask containing a nutrient medium from which they could form their products, after a time the growth stopped, just like peptic digestion, where the products choke the action of the ferment. It was hardly possible, he thought, that the small amount of products which might be present in the body after the injection of the attenuated virus could choke the growth of the virulent bacillus by their own action, but it is not improbable that the profound effect which they

had on the blood might diminish the advantages which that liquid possesses of serving as a nutrient medium for the bacillus. He did not pretend that what he had stated explained immunity, but they were matters for thought and for future experimentation, as showing that there was something beyond phagocytosis in the question of immunity.

VIII.—ALMROTH E. WRIGHT, M. D. DUB.,
Late Grocers' Research Scholar

Dr. Wright said he did not intend to enter upon the main issues of the debate, as he had no original observations to communicate which had a direct bearing upon phagocytosis as a method of resisting disease. Without, however, taking a side as a "phagocytist" or a "humoralist," he might perhaps be permitted to bring into hotchpot a few observations upon the subject of chemical immunity which might turn out to be pertinent to the matter in discussion.

The history of the subject he had been engaged upon was shortly as follows: The late Dr. Wooldridge, in 1888, described a method of what he termed "chemical protection" against anthrax. He found that when he administered tissue fibrinogen to rabbits they remained immune against a subsequent injection of anthrax. He employed tissue-fibrinogen solutions, which were prepared either from the thymus or from testicles, and which he subsequently boiled in order to render them sterile. His results did not appear to have been uniformly successful, and he seemed to have attributed the failures in great part to the fact of his protective fluid becoming inert during the process of boiling. Dr. Wooldridge died, and his work was left in this incomplete condition.

Mr. Hankin, of Cambridge, in whose mind a somewhat similar idea with regard to to chemical protection had been simmering before the date of Wooldridge's publication, was the next to take up the matter. He adopted the term "defensive proteids" for the albuminous substances in which protective chemical properties were supposed to be resident, and he proceeded to graft the idea of a bactericidal power on to the more generic conception of a defensive proteid. He suggested, for instance, that if Wooldridge's tissue fibrinogen really conferred an immunity against anthrax, it probably conferred that immunity by virtue of a bactericidal property with which it was endowed. Dr. Wright gathered that Mr. Hankin had since abandoned this suggestion.

The next observation of Mr. Hankin which he wished to bring into relation with Wooldridge's work was his observation that a particular substance—or more probably mixture of substances—of protective virtue could be extracted from the spleen of the white rat—that is, from the spleen of an animal which was known to be relatively immune against anthrax. This substance or mixture of substances, under the name of an alexin, was, if he understood Mr. Hankin aright, to be considered responsible for the measure of immunity which the white rat possessed over the more susceptible brown rat. He would endeavor to deal very briefly with the work of those two observers.

With regard to Wooldridge's work, it was obviously necessary to reopen the investigation of the subject by repeating his experiments, and then proceeding to isolate the constituent to which the immunity was due. It also seemed desirable to adopt some more appropriate method of sterilization than that of boiling, for Wooldridge himself had recognized the disadvantages which were associated with this method.

Dr. Wright attempted to do these three things in a paper which was read at the International Congress for Hygiene last year.* He there showed that sterilization by means of a Chamberland's filter might with advantage be substituted for the method of heat sterilization. He further showed that tissue fibrinogen was a proteid substance which belonged to the class of the nucleo-albumens or nucleo-proteins. Lastly, he reported several series of experiments in which he succeeded, by means of tissue-fibrinogen injections, in prolonging or preserving life in rabbits which had been inoculated with virulent anthrax.

Certain defects in his experiments in the matter of preserving his tissue-fibrinogen solutions in an absolutely aseptic condition throughout the experiments he had since remedied, and had obtained exactly the same results with absolutely sterile solutions. The results of his experiments on anthrax were that he had never made a series of experiments without obtaining either a prolongation of life or a complete cure by means of the tissue-fibrinogen injections. The results were, however, as yet by no means satisfactory, and there were difficulties to be contended with in the matter of the attenuation of the tissue-fibrinogen solutions during sterilization by the retention of the tissue-fibrinogen on the pores of the filter.

Having got thus far, he was naturally anxious to obtain some information as to the

**British Medical Journal*, September 19th, 1891, p. 641.

manner in which this curative property of tissue fibrinogen became effective. He found, in conformity with Wooldridge's previous observations, that anthrax could be got to grow in tissue-fibrinogen solutions. He therefore concluded that whatever the effect of tissue fibrinogen might be due to, it was clearly not due to a bactericidal power. Mr. Hankin, he believed, agreed with him in this.

Dr. Ruffer had suggested to him at the outset of his work that tissue fibrinogen might possibly act as a cell stimulant. From this, and from a paper of Groth* upon the effects of an intravascular injection of leucocytes he had turned his attention to the examination of the blood and to the enumeration of the leucocytes after tissue-fibrinogen injections. These enumerations gave at once some very tangible results. In every case the injection of tissue fibrinogen was observed to be followed by a remarkable increase in the number of leucocytes. He had repeatedly seen them increased to as much as six times their normal number, and at the same time a remarkable poikilo-leucoytosis made itself felt, some of the corpuscles being of enormous size, and others, again, of very diminutive size. At this stage of the paper he came across the very remarkable paper of Horbaczewski's† upon the physiological effects of nuclein.

Now, since he had shown in his previous paper that nuclein was a constituent of tissue fibrinogen, and since Horbaczewski proved that the admistration of this nuclein resulted in the production of a leucocytosis, he naturally turned to investigate whether the protective effects of a tissue-fibrinogen solution could be obtained by an adminstration of its nuclein moiety alone. He anticipated that he should incidentally reap the advantage of an exact dosage, and also an advantage in the matter of obtaining aseptic solutions with greater facility. He had only just begun the investigation of the matter, but had already been able to satisfy himself that a very remarkable prolongation of life resulted from he administration of the nuclein before an anthrax inoculation, and that this prolongation of life was associated with an increased leucocytosis.

In what relation did this chemical protection stand to Mr. Hankin's researches on immunity? Mr. Hankin obtained his alexin from the spleen of the relatively immune white rat. He obtained it by extracting it with what was practically a normal saline solution. If there were any tissue fibrinogen present in an organ a watery solution would extract it, and in the spleen, where there were leucocytes in relatively large quantities, the main constituent of leucocytes, that was, tissue or cell fibrinogen, must of necessity be present. Therefore Mr. Hankin's extracts of white rat spleens would contain tissue fibrinogen. Mr. Hankin's next proceeding was to precipitate his watery splenic extract with alcohol, redissolve the resulting precipitate in water, and to employ this last extract, after dialysing away the salts, as a protective fluid. The method of preparation was an almost ideal method for ensuring the presence of tissue fibrinogen in Mr. Hankin's final solution, for while the alcohol precipitation might exclude other elements which might be present in the splenic extract, it certainly could not exclude the tissue fibrinogen, for this substance was not rendered insoluble by alcohol.

He thought, therefore, that Mr. Hankin's alexin was the same thing as Wooldridge's tissue fibrinogen, or at any rate that it could not fail to be contaminated with it. In this connection he would point out that the nuclein with which Horbaczewski's experiments were conducted was prepared from the leucocytes of the spleen. With regard lastly to Mr. Hankin's observation that his alexin was found only in the spleen of the relatively immune white rat, he suggested that this might possibly depend upon a greater development of the adenoid tissue of the spleen in the white rat, for it was well known that the spleen played an important part in the conflict of the organism with the micro-organism of disease. A greater development of adenoid tissue would go hand in hand with a larger percentage of tissue fibrinogen in the extracts.

In conclusion he adverted for a moment to the newer development of the Metschnikovian doctrine which aimed at the reconcilement of the opposing schools of phagocytists and humoralists by assuming that the disintegration products of the white corpuscles played a part in the conflict of the organism with infective disease. Each of these chemical disintegration products might possibly act in a protective manner by virtue of either a chemiotactic power, a bactericidal power, or a cell-stimulating power.

Dr. Ruffer had determined for him that tissue-fibrinogen solutions had a powerful positive chemiotactic power. The observation seemed to him of interest as it might help to explain how fresh leucocytes might be attracted to the seat of infection the bacteria

**Dessert*, Dorpat, 1884.

†*Sitzber. d. Wiener Acad.*, C. Abth., April, 1891.

having gotten the better of the first leucocytes which had arrived on the scene.

With regard to the bactericidal power of tissue fibrinogen, it seemed to him that the question had not finally been decided in the negative as his observations on growing anthrax in tissue-fibrinogen solutions were made upon tissue fibrinogens derived from the testicle, and there might conceivably be points of difference between the two varieties of tissue fibrinogen. On the other hand, he thought that great caution was required in inferring from a bactericidal property of a solution in a test tube to the bactericidal power of the same substance in the organism, because such a substance, for instance, as tissue fibrinogen was rapidly broken down inside the organism.

With regard to the cell stimulating powers of the products of the decomposition of leucocytes, it has already been seen that tissue fibrinogen possessed such powerful stimulating properties. He thought that tissue fibrinogen and nuclein might be regarded as cell manures; for by whatever method these substances were introduced into the organism, they were invariably found to produce a leucocytosis.

IX.—J. G. ADAMI, M.A., M.B.,
Fellow of Jesus College, Cambridge.

When the time allowed to each participant in this evening's discussion is necessarily so short, perhaps the best method of attacking this subject of immunity is to start with the best and most complete series of observations in the case of one disease, observations that are both recent and reliable, and then, accepting the facts so gained, to observe how they oppose or confirm the various theories which have been brought forward. For this purpose I would select the very full and pregnant research of Klemperer upon pneumonia. The result of these observations may be briefly stated as follows:

1. Immunity against pneumonia can be bestowed upon susceptible animals by introducing in the tissues the sterilized products of growth of the pneumococcus. This immunity is, in general, but of a temporary nature.

2. Such immunity induced by injection of bacterial products does not immediately manifest itself; indeed, fourteen days must elapse before the simple products bring about their effects. But if the sterilized products be heated either to 106° or 107.5° F. for three or four days, or to 140° F. for two hours, then injections induce immunity within four days.

3. The warmed "vaccine" leads to a reaction of but short duration; the unwarmed brings about a long-continued febrile state at the end of which the animal becomes immune.

4. Thus the fever, with its elevation of temperature, and the antecedent heating of the vaccinal material induce the same result. One or other process would seem to be necessary in order that sterilized bacterial products develop immunity.

5. But, further, the blood serum of a "protected" animal injected into the veins of a susceptible animal confers immediate immunity. There is no delay. Evidently, therefore, some substance is present in the blood serum of an animal made immune—a substance not present in the sterilized culture fluids of the pneumococcus. The bacterial products, therefore, do not *per se* bring about immunity, but, through the febrile reaction, some other body, having immunity-conferring properties, is gradually developed.

6. What is more, this same substance has curative properties, acting, not so much on the pneumococci themselves (for in its presence these continue to proliferate), but upon the poisons or toxines manufactured by them.

7. Hence Klemperer distinguishes two proteids, the pneumotoxine, which can be isolated from cultures of the pneumococcus, and the anti-pneumotoxine, to be obtained from the serum of immunized animals.

It is unnecessary for me to dilate upon the way in which this work of the two Klemperers fulfils and elucidates the previous observations of Salmon and Smith, Christmas, Roux and Chamberland, Hankin, Bouchard, and his school, Brieger and Fraenkel, etc., upon bacterial products, of Wooldridge, Christmas, Hankin, Buchner, Hankin and Martin, Tizzoni and Chattani, and Fraenkel upon proteid bodies capable of inducing immunity, and, in the case of some of these observers upon the antitoxic properties, as opposed to the bactericidal properties of such proteids. Nor need I do more than point out the light that these observations throw upon the meaning of the febrile state. Evidently, as shown by a large number of recent studies, the phenomena of infection and immunity are at base chemical; certain substances are produced by the bacteria on the one hand, by the organism on the other, whose action is of a chemical or chemico-physical nature.

But now comes the question, how is this action exerted within the body? Are bactericidal and antitoxic substances normally free in the blood, are they developed within

special cells, or are they generally distributed throughout the tissues of the body?

In the first place it cannot be too strongly insisted that their presence in blood serum is no certain indication of their presence in blood plasma. Blood serum and blood plasma exhibit marked differences in their characters, and nothing is more marked than this difference in the bactericidal powers of the two fluids. An animal which is most susceptible to a given disease has time after time been shown to yield a serum capable of destroying large numbers of the micro-organisms causing that disease; and, at the risk of repeating what is well known to many, I would again call attention to Lubarsch's classical observation, that whereas 10,000 to 12,000 anthrax bacilli are all that can be injected into the circulation of a rabbit without causing a fatal disease, one cubic centimetre (15 minims) of the blood serum of such a rabbit will in a few minutes destroy the same or a much greater number of the bacilli. While I am far from convinced that under no conditions the plasma can become bactericidal or antitoxic, I still think that sufficient satisfactory evidence has not yet been brought forward in support of the humoral theory. The cases mentioned by Professor Klein are not without a flaw; the rapid diminution of the number of bacteria present in arterial or venous blood is not conclusive evidence that these bacteria have undergone destruction in the blood plasma (phagocytosis being as yet undeveloped). Professor Klein and the humoralists have to bring forward surer proof than has yet been adduced that the bacteria, as foreign bodies, have not been arrested in the capillaries of various organs, and that the diminution of their number in the circulating blood is not caused by such a filtration process.

Again, while I am prepared to admit freely that bactericidal and antitoxic substances may appear or be developed in the cells forming many of the tissues of the body, I hold that it has yet to be proved that this can obtain to any great extent. We are still without proof that, save in the case of organs formed largely of leucocytes and potential phagocytes, the tissue can have powers at all comparable to those possessed by the serum and body fluids. We therefore are driven to a third possibility, namely, that the difference between serum and plasma depends upon an alteration in the condition of the white corpuscles, and that the leucocytes are a most essential factor in the production of immunity. There is not time here to bring forward all the arguments in favor of this view, but this I may say: what other interpretation is to be placed upon (not simply the engorgement, but) the enlargement of lymphatic glands, the enormous increase in the number of white corpuscles in the blood in zymotic disease (under conditions to be referred to later), the determination of leucocytes towards legions of bacterial invasion, unless it be that the leucocyte plays a most important *rôle* in protecting the organism? It is true that there are conditions in which it is wanting. In pneumonia, for example, as Tchistovitch has shown, where the virus is not very powerful there an increase occurs, where the virus is very strong there a diminution is to be made out in the leucocytes of the blood. The same occurs in regard to the amount of diapedesis resulting after local invasion, this depending upon the virulence of the invading organism. Taking into consideration general rather than local infections, we learn that the leucocytosis is dependent upon the reaction of the organism to the soluble products of the virus.

That the leucocytes can possess bacteria-killing powers is supported by Hankin's observations upon the lymphatic glands and spleens of refractory animals, in which he showed that from these organs, composed as they are largely of mature and immature leucocytes and the parent cells of the same, can be obtained a bactericidal substance acting specifically upon the microbes to which the animal was refractory. It is impossible for me to criticise Dr. Woodhead's objection to this—namely, that Dr. Wright has grown micro-organisms freely upon leucocytes—until the conditions of these experiments have been fully described.

To come now to the assumptions of bactericidal powers by blood serum, I would remark that, as Reuschenbach has shown, and as a matter of common experience, coagulation of the blood and production of serum is accompanied by a great disintegration of certain of the white corpuscles,* and I would suggest that to this disintegration is due the presence of bactericidal substances in the serum. Just as from fresh blood, and intact white corpuscles no fibrin ferment is obtainable, so it may be that the intact leucocytes do not *normally* contain bactericidal substances but precursors thereof. Possibly this is fitted to explain Dr. Woodhead's contention with reference to quinine.

I am unwilling that this working hypothesis whereby I have attempted to reconcile for the time being the divergent results of a host of capable workers should be dubbed a theory,

* Upon these points see fuller details given by Dr. Wright in the *Lancet* of February 27th.

still more do I regret that it should have been accredited to me; for while I have worked it out along my own lines, its origin is to be found in Mr. Hankin's work, and to all intents and purposes this is the hypothesis brought forward by Hankin at the International Congress of last year. If for no other reason, I am glad to join in this evening's discussion in order that honor may be given where honor is due.

Lastly, as to the way in which the leucocytes act upon the bacteria, I cannot help being impressed by the fact that the more perfect the methods employed the greater is the phagocytosis observable in the course of resolution of disease; and I must conclude that even though leucocytes have other methods of acting upon bacteria and their products, phagocytosis is a most important, probably the most important, factor in the production of immunity. Professor Burdon Sanderson's main objection—that leucocytes are to all intents and purposes independent organisms, and that, therefore, they cannot reasonably be expected to act in accordance with the needs of the organism—is, it seems to me, based upon the idea that the leucocytes are generation after generation propagated in the blood, free from the fixed cells of the body, But this is scarcely the accepted view. Very little mistosis of the leucocytes occurs in the blood, whereas the characteristic mistotic areas in the lymph glands offer an almost certain indication that the proliferation of leucocytes occurs in regions where the parent cells may be regarded as fixed, and capable of being influenced by nervous and other stimuli. It is to these parent cells, rather than to the free, motile leucocytes, with their short span of life, that we must look to explain continued powers of resistance to bacterial products on the part of leucocytes, the development of increased resistance, the development of immunity.

X.—T. J. BOKENHAM, L.R.C.P., M.R.C.S.,
Research Scholar British Medical Association.

Mr. Bokenham gave the results of some investigations on erysipelas which would have to be explained before the question of the causation of immunity could be settled: (1) Different effects of injecting cultures of true steptococcus erysipelatis into rabbits and guinea-pigs. Inoculation of a virulent culture into a rabbit's ear produced a typical spreading erysipelas without pus formation, though the lymph, whilst the process was advancing, was very rich in leucocytes. If some of this lymph were injected into a guinea-pig and another rabbit, the latter would contract a disease in every respect similar to that in the first rabbit, but nothing would happen to the guinea-pig. (2) Alteration of virulence of streptococcus erysipelatis under varied conditions: If a culture of streptococcus erysipelatis (too attenuated to produce the disease in a normal rabbit) were injected into one into which a simultaneous intraperitoneal injection of a sterilized culture of bacillus prodigiosus had been made, typical erysipelas would appear at the point of inoculation.

In this case a rabbit which was immune to the erysipelas of a low virulence was made susceptible, and inoculation from it to a normal one would produce the typical disease in the second; and, by continuing the process through successive rabbits, a very virulent form of erysipelas could be produced in which a highly infective disease occurred with generalized symptoms, though no reaction occurred at the point of inoculation. Here undoubtedly the local cellular infiltration seemed to have played some part in the localization of the disease. If a rabbit vaccinated against the bacillus pyocyaneus were inoculated with streptococcus erysipelatis, a general fatal infection occurred without local reaction at the seat of inoculation, but blood from this rabbit could only produce the local disease in a normal rabbit. Association of attenuated erysipelas with a common mould increased the virulence of the streptococcus both generally and locally.

HARD CHANCRE OF THE LIP AND SOFT CHANCRE OF THE GENITALS.

Dr. P. I. Messarosh relates, in the *Meditsinskoye Obozrenie*, No. 17, 1891, the case of a young man, 20 years of age, who presented himself at the Astrakhan General Hospital for treatment of a sore lip. Examination revealed the presence of a true Hunterian chancre on the upper lip, and also a soft chancre of the penis. The patient stated that he had accidentally bitten his lip some time before, and that soon thereafter a sore appeared which refused to heal in spite of numerous domestic remedies which he had applied. While the man was still under treatment a woman presented herself for treatment for syphilis. She was found to be suffering from general syphilis, having mucous patches in the mouth, and also from soft chancres in the vagina. This woman, it was subsequently ascertained, was the mistress of the other patient, with whom he had lived for several months, and from whom undoubtedly he had acquired his lesions.

PUNCTURED FRACTURE OF THE SKULL TREPHINE AND RECOVERY.

By A. D. BINKERD, M. D.,
WEST MONTEREY, PA.

On Sunday about 10 o'clock A. M., Sept. 13th, I was called to see H. L——, who had jumped from a rapidly moving train and sustained serious injury. He was picked up within fifteen minutes, unconscious and bleeding from a small scalp wound over the occipito-parietal suture, a little back and probably two inches above the tip of the ear on the left side of the head. It seems highly probably that the car struck the patient after he jumped, and that some sharp point produced the punctured fracture. There was a severe contusion of the deltoid muscle with abrasion of the skin on the upper third of the arm on the same side. Thorough examination discovered no fracture other than a small puncture and angular depression of both plates of the skull beneath and a little forward of the clean laceration of the scalp.

There were evident symptoms of both concussion and compression of the brain. The pulse was slow and feeble. Respiration twenty-four. The patient vomited and remained in a semi-comatose condition all night.

In the morning I telegraphed for Dr. R. S. Wallace, of East Brady. On his arrival he confirmed my diagnosis.

After a liberal use of Squibb's ether, Dr. W. proceeded to remove a button with the trephine, just beneath the puncture, but so sharp and angular was the depression that we found it impossible to raise the plates without removing them bodily, which we did.

Little spiculæ of the inner plate had been thrust into the dura mater. These were carecarefully removed. The hæmorrhage was profuse and the operation necessarily consumed considerable time owing to a scarcity of trained assistance.

When the work was done the convolutions of the brain were exposed, fully three cm. by two cm. in extent.

The hæmorrhage was kept under control and the integument brought into apposition by sutures, the whole being done antiseptically, as nearly as possible.

In due time the patient rallied from the anæsthetic, but symptoms of compression continued till the next day, when they gradually disappeared. There was perceptible dilatation of the pupil on the side of lesion.

Fifteen grains of the bromide of potassium with three drops of tincture of aconite root every three hours with cold compress were agreed upon as the treatment for the first few days. This was strictly carried out. Second day we began calomel, four grains every four hours; this was continued for several days, keeping a sharp lookout for the blue line. A low diet and absolute quiet were required. Kidneys acted well, but there was torpidity of the bowels.

About the fourth day fever began to rise. Temperature 104.° Pulse 120. Respiration 26. Symptoms of herniæ cerebri, so much dreaded by Dr. D. Hayes Agnew, began to threaten as a new complication. It now happened that we had a very hot day, being nearly the hottest in September. The effect upon the patient was severe and to some extent alarming. Arterial hæmorrhage was controlled with difficulty at one point only to burst forth anew at another with increased vigor. A tumor, the size of a hen's egg, had forced itself through the wound. This had little tendency to calm the fears of the friends and parents. Calling to my aid the "lost art" of phlebotomy, I took blood from the arm in a full stream, till the patient expressed relief from pain.

The battle for ascendency continued for four days and nights, when improvement began.

The bromide and aconite were continued. In due time the bowels were evacuated, and the secretions established. Milk and bread constituted the chief diet. A ripe peach was allowed daily, then ripe cantaloupe or musk melon. During the second week thoroughly boiled wheat served with cream and sugar aided in keeping up gentle action of the bowels.

Delirium and incoherence were controlled by fifteen grain doses of chloral hydrate with bromide. A three to five grain capsule of quin. sulph. daily constituted the tonic from the second week.

The wound was thoroughly cleansed twice daily with standard antiseptics. Very little suppuration occurred.

The dropping of the scalp over the abrupt edge of the skull now gave us some concern, and the effort to prevent this natural phenomenon by inserting a pin, and thus bridging the scalp, did not result in any apparent benefit to the cicatrice.

The wound had now diminished to the size of a large corn grain, but refused to recede farther. One day while cleansing the wound I discovered a hard white substance which I could not readily remove. The next day I took it away. It was a fragment of the inner plate $1\frac{1}{8}$ in. long and $\frac{3}{8}$ of an inch wide. Some ten days later I removed another small spicula.

The young man had begun to gain in weight, slept well, with increasing appetite, and had general good health.

Dizziness in walking was not a prominent feature. But he has as yet no recollection whatever of the occurrence of the accident.

The contusion of the shoulder resulted in resolution by suppuration, and showed a marked sluggishness in healing, yielding, finally to iodine injections supplemented by the seton.

This young man is 20 years of age, and was in robust health at the time of the accident. He has been at work in a rolling-mill in Pittsburgh since the first day of January, 1892, being less than four months after the occurrence of the accident.

Though we advised him strenuously against the resumption of physical labor till a considerable time had elapsed, he says he feels about as well as he ever did.

At this writing, careful inquiry elicits the fact that there exists a perceptible transudation from a small area beneath which it is highly probable a small fragment of dead bone still remains.

That the natural covering of the convolutions of the brain which we removed by the operation has been in part restored by analogous tissue is highly probable. Whether the process of restoration will continue to completion and possible compression of the subjacent convolutions of the brain, or whether the arch will be sufficiently concave to prevent such compression and its consequences, is the important point yet to be determined in this case— a point in which all brain surgeons must be vitally interested.

REPORT OF A CASE OF OVARIOTOMY.*

By DRS MARTIN AND CRAWFORD,
KAHOKA, MO.

Jan. 3d, Mrs. B——, aged 61, consulted Dr. Martin concerning a growth or tumor in the abdomen, which was of rapid growth and producing a variety of distressing symptoms. The abdomen was enlarged to the size of full term of gestation, the uterus was crowded down into the vagina; the breathing was interfered with from pressure against the diaphragm; the bladder could not be emptied except while in recumbent position, and the patient would then lift the tumor with her hands so as to remove the pressure from the neck of the bladder, and allow the urine to dribble away while in this position. These, with other distressing symptoms, were sufficient to cause the patient to willingly consent to the performance of an operation for the removal of the tumor, which we diagnosed an ovarian fibroid cyst.

We began to prepare her for the operation by giving her supporting and tonic treatment, with saline cathartics to free the bowels the day previous to the operation, enjoining daily baths and strict cleanliness of clothing and bed. On Jan. 14th, with the assistance of Dr. H. W. Stover, of Kansas, and other necessary help, we removed the tumor by first using all the care possible with regard to complete antisepsis, believing that success in all cases of laparotomy depends more upon thorough and complete antiseptic measures than any other one thing.

Our instruments and everything to be used were first placed in boiling water and afterward submerged in a solution of bichloride of mercury; the hands of operator and assistants were bathed in the same. The anæsthetic used was a combination of chloroform, ether and alcohol, one and a-half ounces of whisky being given a few minutes prior to administering the anæsthetic, which was given her while in bed. She was then placed on the operating table, and the operation commenced by making an incision from immediately below the umbilicus down to the linea alba to pubic arch, through integument, fascia and muscles to the peritoneum, waiting a few minutes to use sponge and ascertain if any vessels claimed attention. Just here we will say, that less than one ounce of blood was lost in the entire operation. The peritoneum was cut through and the tumor brought to view; it was found to be adherent to peritoneum and slightly so to intestines.

Notwithstanding the incision was six inches long, we decided to puncture the sack before removal, which we did and drew off about four quarts of gelatinous fluid, greyish in color and of the consistency of strained honey.

The adhesions were then broken up and the tumor lifted out of the abdomen by the hands of the operator; its attachment was then found to be the broad ligament on the right side of the uterus. The pedicle was two inches long and about two and one-half inches wide; we now passed a large needle, armed with double silk ligature, through centre of pedicle and tied from both sides. After which, we used a heavy ligature encircling the entire pedicle; we then excised and laid the tumor aside, sponged out the abdominal cavity, examined the stock to see if any bleeding ensued and immediately began to

*Read before the Tri-State Medical Society at Keokuk, March 1, 1892.

close the wound by fixing the pedicle at lower angle of incision and fixing it firmly there by pins and sutures; continuing sutures every inch or less until the incision was entirely closed.

After drying the body, we placed a layer of absorbent cotton, previously baked in the oven, over the incision and placed a bandage of new white flannel neatly about her and laid her back in bed where just thirty minutes before we had taken her out for the operation. She endured the anæsthetic well and the shock soon passed off, so that only a few minutes after she reached her bed she regained consciousness, and one hour later felt comfortable and took nourishment. We allowed no solid food for fifteen days, held the bowels in check for eight days, at which time we used injection and bowels responded nicely. The only medicine given was an anodyne of Tully's powder every ten or twelve hours; we saw her daily for seven or eight days and occasionally thereafter for the next three weeks. At no time did the temperature rise above 100°, and the pulse was at no time above 90. Soreness was slight from the beginning and no actual pain was experienced, the incision healed by first intention. Patient slept well and expressed herself as having felt more comfortable at the end of the first week than she had for seven months prior to the removal of the tumor. After ten days the patient began to sit up in bed, could turn herself without assistance, and now, at the end of thirty days, can walk about the house, and is entirely well.

We did not weigh the tumor, but believe it would, together with contents, have weighed 13 or 14 pounds. The usual weight of the patient is about 90 pounds.

APPOINTMENT OF RESIDENT PHYSICIANS AT EPISCOPAL HOSPITAL.

An examination for the position of resident physician in the Methodist Episcopal Hospital, of Philadelphia will be held on Tuesday, March 29th, 1892, at the hospital, Broad and Wolfe Sts., Philadelphia, at 8 p. m.

The examinations is open to both men and women; but applicants must, in accordance with the charter of the hospital have the degree of Bachelor of Arts. Two residents will be selected by the Trustees from the candidates who obtain the first four places in the examinations by the Medical Board.

Applications to be made to

Dr. John B. Roberts, 1627 Walnut St.
Dr. Richard C. Norris, 1028 Spruce St.
Dr. Wm. C. Hollopeter, 1408 N. 13th St.
Dr. H. H. Kynett, 1728 Spring Garden St.

SOME REMARKS ON SCARLET FEVER.*

By A. F. HEISING, M. D.,
MENOMINIE, WIS.

The etiology of this dreaded disease is no doubt due to a specific germ not yet perfectly isolated. The poison having entered the system either by ingestion or inhalation permeates the blood and the contents of the miliary vesicles, as experiments on healthy individuals prove. It has been observed that the contagion is manifested throughout the course of the disease, especially when desquamation takes place, the viability of the germ extending even from 5 to 8 weeks after the cessation of the disease.

When we speak of scarlet fever, we invariably consider it a disease of childhood, yet even adults, as your own experience proves, are not entirely exempt. Women in the puerperal state seem very susceptible to it, and I have no doubt that many a time a physician has mistaken this disease for some septic condition. Children having open wounds, as observation teaches, are more liable to take it.

It is a common opinion among the laity, that scarlet rash and scarlet fever are quite different diseases; yet in what really does the difference consist but in the intensity of the poison?

The prodroma are uncertain, usually a sudden chilliness with angina seems to initiate the disease, followed by vomiting and occasionally convulsions. On the second or even at the close of the first day a characteristic eruption of small red dots closely crowded together, makes its appearance, first on the chest and face, becoming general as the disease progresses, reaching its limit on the fourth and fifth day.

The temperature on the third day is usually the highest, subsiding from the fifth to the ninth day by lysis, unless other complications arise. Comparing pulse and temperature, the former is rather rapid. Next to the temperature, the throat symptoms are almost invariably present, although I have heard of cases in which they were absent. The severity of the throat symptoms may differ from an ordinary angina, with enlarged mucous follicles and suppurating portions of tonsil to the diphtheritic form.

Last spring diphtheria almost decimated its victims in our city, at the same time scarlet fever also prevailed, and I noticed that the throat symptoms of scarlet fever

*Read before the Inter-County Medical Society, March, 1892.

patients were by far more severe. I cannot help but think that many a time the two are closely allied, but in those cases assuming the diphtheric form, I never noticed the occasional paralysis which follows diphtheria. If a person can have diphtheria and scarlet fever simultaneously, one thing is certain, that while the scarlet fever is aggravated the characteristic diphtheria is mitigated.

Whether the Klebs'-Loeffler bacilli and those of scarlet fever antagonize each other, future experience and study will reveal. Bacteriologists teach us that we are surrounded by countless microbes, that almost threaten to devour us while our system is unaware. That they may be parasitic and thus antagonize one another, I would not be willing to say; but if this be true, that a person may have both diseases simultaneously and that one mitigates the other, who knows but many others may be found that will act in the same way and open up a new avenue of treatment?

The swelling of the glands in the neck, followed occasionally by an abscess, is of no rare occurrence, especially in the diphtheritic form. It seems strange that children having purulent otorrhœa after scarlet fever very seldom have meningitis.

Considering the elimination of the disease partly through the urinary tract, we ought to be prepared for the kidney complication, thus a timely examination of the urine in the third week may warn us of the approaching complication.

The fact that patients may have had the disease lightly does not vouch for the escape of nephritis. I remember a family in which eight children were taken down with the disease, one of the number had it very mildly, but he suffered with the worst uræmic convulsions and vomiting I ever saw, necessitating almost all medicines to be administered hypodermically.

I would call your attention to the fact that in the early stage of the nephritic complication, I have noticed pains in the abdomen opposite the kidneys. This may be misleading at times, yet it is a fact that pains are not always felt in the organs affected.

The pneumonia noticed in scarlet fever seemed to be more the result of kidney complication. Friëdlander has found that an acute nephritis of only a few weeks' duration resulted in hypertrophy of the left ventricle.

It is a peculiar fact that after desquamation there is occasionally articular rheumatism.

As to treatment, I suppose there is a great variety, nevertheless similar to a great extent in principle. As a preventive, I have tried *salol.* In some cases it seems to act perfectly well, while in others it is of no avail. In the early stages when marked symptoms of over-poisoning are manifested, I use potassium chlorate in doses to suit the age of patient every two or three hours. For the throat symptoms I use peroxide of hydrogen every two or three hours. Hot fomentations applied early to the swollen glands of the neck abort abscesses. For the fever, sponging with cold water or the cold pack whenever indicated. In order to be on the safe side, I usually give a mixture of digitalis and sweet spirits of nitre in doses to correspond with the age of the patient. This seems to cleanse the kidneys and thus many a complication may be avoided. This solution I also use in the case of nephritis. To prevent further contagion I order the patient to be anointed with carbolized vaseline, while all the clothes are either burnt or soaked in a suitable germicide solution. When the bowels are constipated calomel acts very nicely.

I may have omitted many points in the treatment, but in 70 cases I have lost but seven, three in the early stage from over-poisoning, two from nephritis, one from post-pharyngeal abscess, another died from some cause which I could not ascertain.

BRONCHITIS MIXTURES.

The following seasonable excerpts are from *Guy's Hospital Gazette:*

℞

Carbonate of ammonium	grains	16.
Syrup of tolu	fluid oz.	½.
Tincture of squill	minims	40.
Compound tinct. of cinchona	fluid drachms	2.
Spirit of chloroform	minims	4.
Rose-water	fluid oz.	2.

Mix. Dose, 1 fluid drachm every four hours.

Dr. J. Davies says of this that it is "stimulating expectorant in bronchitis and pneumonia."

Dr. W. T. Caldwell says that "for chronic bronchitis in old people, dispensed as a solution, preserved with a little spirit, the following is much preferred to taking as a pill. The quinine acts as a germicide, and the purulent discharge is removed."

℞

Sulphate quinine	grain	1.
Extract of hemlock	grains	3 to 5.
Dilute hydrobromic acid	minims	4.
Water to	fluid oz.	1.

Mix. Dose, 1 fluid oz. every four hours.

Another, of which Dr. R. Woods speaks highly, is:

℞

Tartarated antimony	grain	¼.
Spirit of chloroform	minims	12.
Tincture of opium	"	7.
Burnt sugar	grains	3.
Water to	fluid oz.	1.

Mix. Dose, 1 fluid oz. three times a day.

SELECTED FORMULÆ.

CONSUMPTION.

The following (*O Galenos*, Etos I, Arithmos 9) is praised for internal administration in pulmonary tuberculosis:

℞ Creasot. pur.....fl. ʒ j.
Spirit vini.....fl. ʒ iijss.
Vini Santorini.....fl. ʒ x.
Syrup simplicis.....fl. ʒ iljss.
A large spoonful three times a day.

ANTISEPTIC TREATMENT OF PTYRIASIS VERSICOLOR.

The pathogenic rôle of the *microsporon furfur* is secondary, the parasite developing only on the skin of dyspeptics affected with seborrhœa. Hence, there are two indications in the rational treatment of this affection.

General and Antidyspeptic Treatment.—(1) Encourage intestinal evacuations by purgatives, salicylate of magnesia, castor-oil. (2) Associate intestinal antiseptics with these purgatives and with alkalies.

℞ Bicarbonate of soda,
Salol,
Magnesia.....āā grammes 5.
Divide into fifteen powders and give one before each meal.

Local Antiseborrhœic and Parasiticide Treatment.—(1) Each morning hot lotions and frictions with green soap, allowing the foam to dry on, and subsequent cleansing bath with plenty of water. (2) Every second day, sulphur baths followed by frictions with green soap, with the addition of naphthol or pumice-stone.

℞ Green soap.....grammes 500.
Finely pulverized pumice-stone " 250.

(3) Daily antiseptic inunctions with the following mixture:

℞ Resorcin.....grammes 5 to 10.
Ol. ricini..... " 45.
Spt. vini rect..... " 150.
Bals. Peru.....centigr. 0·50.

or,

℞ Acid. salicylic.....grammes 2 to 3.
Sulph. precip..... " 10 to 15.
Lanolin..... " 70.
Vaseline..... " 18.

—*Revue Gén. de Clin. et de Thérap.*, No. 49, 1891.

RHEUMATISM.

The following prescription is a good combination in rheumatism. I have tested it personally, and know whereof I speak:

℞ Pot. iodide.....ʒ iiss.
Tr. cimicifuga.....ʒ iss.
Vin. colch. sem.....ʒ j.
Fl. ext. henbane.....ʒ ss.
Simple syrup.....ʒ v.
M. Sig. Teaspoonful well diluted with water every four hours.

Dr. Conger, in N. E. Med. Monthly.

OTALGIA.

In otalgia the following (*Ugeskrift for Læger*, Nos. 28 and 29, 1891) is recommended:

℞ Chloral camphor.....grammes 5.
Glycerine..... " 30.
Ol. am gdal. dulc..... " 10.
Dip a pledget of cotton into this mixture and introduce it into the meatus.

MONIN'S KOLA ESSENCE STIMULANT.

Essence of kola (roasted).....Gramme 40.
Tincture of canella..... " 5.
Essence of peppermint.....gtt. 10.
Flavor, mucilage.....ad. lib.
Water, enough to make.....Gramme 150
This is to be consumed in 24 hours.

—*Bulletin Medicale.*

EMMENAGOGUE.

The following is recommended as a reliable emmenagogue in many cases of functional amenorrhœa:

℞ Bichloride of mercury,
Arsenite of sodium.....āā gr. iij.
Sulphate of strychnine..... " iss.
Carbonate of potassium,
Sulphate of iron.....āā " xlv.
Mix, and divide into 60 pills. Sig. One pill after each meal.

—*Revue de Médico-Chirurgicale des Maladies des Femmes; Times and Register.*

CHLOROFORM SALVE FOR LOCAL ANÆSTHESIA.

Dr. Kittel (*La Independencia Medica*, No. 42, 1891) uses the following:

℞ Chloroform.....part 1.
Ceræ..... " 1.
Adipis.....parts 3.

APPETIZING TONIC.

℞ Quiniæ sulph.,
Ferri citr.....āā ʒ ss.
M. Ft. capsulæ No. 40. Sig. One after meals.

DIARRHŒA OF CHILDREN.

Dr. E. M. Sympson (*La Semaine médical*, No. 59, 1891) recommends the following:

℞ Borax.....grammes 4.
Glycerin. pur..... " 16.
Tint corticis aurant..... " 3.
Aq. destillat..... " 60.
A teaspoonful every one to three hours.

This is not only an excellent anti-diarrhœic, but also quiets the colic.

WHOOPING-COUGH.

Dr. Schmid (*Lo Sperimentale*, No. 21, 1891) uses the following in a spray with success in cases of pertussis:

℞ Acid carbolic.....grammes 0.03.
Sol. menthol (4 per cent.)..... " 20.
Sol. cocain. (3 per cent.)..... " 15.
Aq. lauroceras..... " 60.
Spray the child's throat once an hour, or even oftener.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO. (Incorporated)
PROPRIETOR AND PUBLISHER.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.)

CHARLES K. MOUNT, Advertising Manager.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates),..... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts,.....$1.50 each.
Bovine Points or Quills,..... 1.00 a doz.
Humanized Crusts,..... 1.00 small.
Humanized Crusts,..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

LEADING ARTICLE.

THE INFECTIOUSNESS, CONTAGIOUSNESS, AND HEREDITY OF LEPROSY.

Professor A. von Bergmann contributes to the *Sammlung klinische Vortraege* an article, which is an interesting and valuable exposition of this subject which has of late been brought so forcibly to our attention, both by the press and clinical experience in the larger cities of the United States.

In the city of New York the subject of the contagiousness of leprosy has become of such importance that the authorities have seen fit to place the matter under investigation, and have decided that the bulk of the evidence goes to answer the question in the affirmative. However, in this decision, no discrimination has been made between what is known as tuberculous leprosy and the variety known as anæsthetic leprosy. There are many authorities whose words cannot be disregarded, who look upon leprosy rather as infectious than contagious.

A. von Bergmann, living as he does in a locality rich in lepra material, has had such a vast experience that his views demand attention. He starts out by saying that he has placed together all cases which came under his consideration without any distinction between the tubercular and the nervous varieties, and as an excuse for this he quotes Danielssen, Dehio, and Gerlach, who consider the scales which come away from the skin in this affection to be parts of a specific lepra tissue. The main distinction between lepra nervorum and lepra tuberosa that he makes is the length of the course which the disease runs; the former lasting often more than twenty years, and the latter ranging from four to twelve years. In contradistinction to these views, we have Kaposi, who at the Tenth International Congress maintained from a practical standpoint the non-contagiousness of leprosy.

Von Bergmann asks: How do the anti-contagionists explain the spread of leprosy? And then goes on to say, "In the first place, through inheritance, next through spontaneous generation, poverty, scant food, special

rancid oil, spoiled and raw fish-roe, and especially from fish food. Hutchinson is a most zealous supporter of the fish nutrition theory, and finds disciples in such men as Hillis, Zambaco, Sandreczki, Wyndham and Cottle. Hutchinson reports more than twelve cases that he observed in London, which without exception emanated from leprous regions and who ran the risk of eating fish, especially salt fish. The beginning of the fish theory dates back to Avicenna. Danielssen and Boeck have investigated fish in Norway which had been attributed as a cause of leprosy, and have between them found examples which possess greater and smaller nodes, and they point to an undoubted relation to the lepra tuberosa. Exact investigation proves that we have to deal here with vegetable parasites.

Petersen and S. Moore allege that on the other hand leprosy appears in people who are remote from the sea, and who never even see a fish. We can, therefore, well pass over the fish theory as long as supporters of the same can bring forth no definite data for the support of the truthfulness of their speculation.

Dr. Bergmann likewise disregards the theory that leprosy is due to extreme poverty on account of the lack of sufficient and exact data to support the theory, and goes on to to say that inheritance of leprosy is considered by most of the auto-contagionists as the chief factor to induce the spread of leprosy.

Kaurin, Carter and A. Wernich have worked out the percentage of hereditary leprosy in Norway, Katywar, East India and Japan. Kaurin finds of the cases of leprosy in Norway 30 per cent. are hereditary. Carter likewise in Katywar finds it to be 30 per cent. A. Wernich finds that hereditary leprosy in Japan is 40 per cent. Out of 107 cases reported by English physicians, in the East India service, 69 cases are put down as undoubtedly hereditary. On the other hand, there are Armauer Hausen and Leloir, Bidenkap, Pr. A. Marrow, J. de Arazedo Lima and many others, who consider that hereditary leprosy can seldom be traced. *A priori*, it is easy to see, that the conditions for the hereditary transmission of leprosy are favorable. The *potentia coëundi* appears in lepers first in advanced stages. The testicles of lepers are very frequently the seat of bacilli and the same has been found by Cornil, Neisser, Hansen and Leloir in the seminal duct. Neisser and Leloir have in a single case found bacilli in the coni vasculosi Halleri. Accordingly it appears that the transmission undoubtedly takes place through the medium of the spermatic fluid.

In a book written by Danielssen and Boeck, in a table of 145 cases of lepra tuberosa, it is shown that 127 cases of the disease were due to inheritance, only 43 were in a direct line of transmission. From these 43 direct cases of inheritance 13 are entirely in the first generation, 25 came from grandparents, one comes from the third and four from the fourth generation. In 145 cases of leprosy, in only 13 cases were the parents leprous; this makes scarcely 9 per cent. A table of 68 cases of lepra nervorum, shows about 10 per cent. of cases in which the parents were leprous. Naturally there are doubtful cases as to the heredity and as to the contagiousness of the disease.

The greatest hindrance to an understanding of the contagiousness of leprosy is conclusively offered in the question of the length of the period of incubation. This period is long, from four to five years intervening between the exposure and the outbreak of the disease.

These cases of direct and indirect transmission are but a handful from the rich material which Von Bergmann has collected. He has handled the matter in a thoroughly scientific way, and the bulk of the evidence from his own cases goes to show that leprosy is contagious and hereditary. He has devoted considerable space to the method of infection, quoting inculation experiments upon animals made with blood taken from leprous patients. In every case of inoculation of the lower animals the results have been negative; of course, the factor of the long period of incubation must not be lost sight of here, even as in other specific granulomata the animal often dying long before the disease has had time to manifest itself.

He has very little to say in regard to the bacillus of leprosy as being its cause, and seems to attach but very little importance to it as a diagnostic factor. After placing all his cases in a table he describes them both separately and in groups and closes his article as follows: "The longer and the more critically that I collect the histories of lepers the easier it is to prove that cases are related that at first appeared isolated. However, it may readily be perceived that these cases furnish a practical support for the theory of transmission of leprosy, for in 60 per cent. of the cases contagiousness is undoubtedly established; in others presumably so. Think of all the cases of diphtheria, scarlet fever, small-pox, *et cetera*, that you come upon in your practice as isolated cases, where in spite of every endeavor you are not enabled to establish the source of infection; also consider the experience which we have had in chronic infective diseases. No one today considers it a proof against the transmission of syphilis, if a syphilitic man inoculates neither wife nor children. Why should it be held for a proof of the transmission of leprosy that man in each case must share his leprosy with his wife. Our material can also be brought to support the length of the period of incubation of leprosy. In not a single case does the same fall below three years, the majority of the cases ranging between four and five years. I believe as soon as the long period of incubation is established, the opposition against its transmission will be silenced."

THE DEATH OF DR. D. HAYES AGNEW.

Dr. D. Hayes Agnew, the greatest American surgeon, died on Tuesday, March 22d, and was buried on Friday, March 25th. An obituary notice will appear in a subsequent issue of the REPORTER.

IT is claimed by good authority that two infectious diseases can exist in the same person at the same time.

BOOK REVIEWS.

TREATISE ON GYNÆCOLOGY, MEDICAL AND SURGICAL, BY S. POZZI, M. D., Prof. Agrégé à la Faculté de Médecine, Paris, etc. Translated from the French edition under the supervision of, and with additions by, BROOKS H. WELLS, M. D., Lecturer on Gynæcology at the New York Polyclinic, etc. Vol. I. Large 8vo, pp. xxiii—581 Illustrated with 305 wood engravings, and 6 full-page plates in color. New York: Willliam Wood & Co., 1891.

The task of the reviewer of this work is a most agreable one. Judging the whole work by the first volume, it is the most important addition to gynæcological literature in recent years. The most striking feature of it is, that it is distinctly in touch with current thought; its matter is neither obsolete nor obsolescent, but everywhere represents what is good in modern progressive gynæcology. Another striking feature is that it is French, and that it sets forth the work of the French in diseases of women from the dark ages down to the present time. The work of all nations is duly credited and with a broad, liberal spirit, but as a true Frenchman, the author never loses an opportunity to bring the work of his countrymen into prominence. This fact gives an added value to the work. Because of the long silence of French writers on gynæcology during the time when writers of other nations have been so prolific, we have rather forgotten the good work which France has done in this department of medicine, and it is well to have the facts recalled to our attention.

Chapter I. treats of antisepsis in gynæcology. This is a useful innovation, as bringing prominently to the attention of the reader the importance of the subject. The only criticism upon this very full chapter is that the editor should have added notes on the use of the steam sterilizer for the sterilization of instruments and dressings; and also the use of sterilized water to cover the instruments during operations, instead of the carbolic solutions. These improvements in technique have become general since the chapter was written by the author. Chapter II. treats of anæsthesia, Chapter III. of methods of suture and hæmostasis, Chapter IV. of methods of gynæcological examinations, each being systematically written. The author still clings to the routine use of the sound and to the use of the tents for dilating the cervix, but the dangers of the practice are pointed out.

Chapter V. discusses metritis, under which head is embraced metritis and endometritis, and laceration and erosion of the cervix.

The classification is adopted because of unity in the ætiology of the conditions—all being inflammatory and due to germ infection. To those who have admitted subinvolution, congestion, and hyperplasia from congestion, and especially those who with Thomas and Emmet have combated the theory as to the inflammatory character of metritis, this classification comes as a shock. The author can easily fortify his position with proofs. For example, subinvolution is almost always due to infection in child-bed, and the condititions brought about by long continued congestion are favorable to infection. As to the primary cause of the conditions embraced under the title "Metritis," being infection in all cases, the author certainly goes too far. Early rising from the lying-in bed can cause subinvolution, displacement of the uterus, and subsequent metritis (a late infection ?). Here the primary cause is not infection, and it is well known that the large hyperplastic uterus is usually found in poor women who bore babies at short intervals, and who go to work while the uterus is still subinvolved. And these illustrations might be extended, by studying the endometritis accompanying fibriods, etc.

The author is a strong advocate of the curette in chronic endometritis when it is complicated, the curetting to be done under strict asepsis. This method of treatment is coming more and more into favor.

The relations between inflammation of the uterus and the uterine appendages are more definitely stated than in any other systematic treatise.

Chapters viii–xvi treat of uterine fibroids and cancer. Chapters xvii–xix, contain 104 pages, treating of displacements of the uterus in a specially complete and admirable manner. It is to be regretted, however, that an exception must be made in the chapter on prolapse of the genital organs. The relation of the injuries of the pelvic floor to prolapse of the pelvic viscera is scarcely hinted at, and yet these injuries are almost always the direct cause of the prolapse. Apparently the author is not familiar with Emmet's operation on the perineum, as he makes no mention of it.

Chapters xx–xxii are devoted to inversion of the uterus, certain deformities on the cervix and uterus, and to disorders of menstruation. The two points in treatment which will not commend themselves to most American readers are the use of tents to secure dilatation of the cervix, and the use of the syringe in making intra-uterine applications. The dangers of the tent as compared with the steel dilator should prevent its employment. The author uses the uterine syringe only after preliminary dilatation and curetting, under which conditions its use is a very different procedure than when the cervical canal is of normal calibre.

The notes of the editor are valuable, and reflect great credit. Unquestionably he has placed the profession under obligations to him for this admirable translation of Pözzi's great work.

CORRESPONDENCE.

THE CHEMICAL STUDY OF THE ÆTIOLOGY OF SUMMER DIARRHŒA IN CHILDREN.

Editor of the Medical and Surgical Reporter :—In your issue Oct. 17th, 1891, page 637, there is an article under the above title, translated from the Italian, and credited to the investigations of Varyas. This is from an article which was read by me before the American Pædiatric Society in June, 1890, and was published in the transactions of that society and in the Archives of Pædiatrics date of Oct. 24th, 1891.

That the article is a translation and condensation of my paper will be evident to any one who will compare the two.

Victor C. Vaughan,
Ann Arbor, Mich.

FLORENCE REDIVIVUS.

A striking example of the beneficent influence of sanitary reforms on the health of cities is afforded by a study of Florentine death-rates before and after the improvements which have been carried out of late years. The ameliorations have consisted for the most part in the prevention of floods, the suppression of private slaughter-houses, and a better water-supply, together with sundry house and street improvements. These are still in progress, but on comparing the death-rate from 1818 to 1877, equal to 34.6 per 1,000, to that of the years in which unsanitary conditions were being dealt with, we find that the returns fall successively to 32.8, 28.6, and, in 1890, to 2g.3, and this in spite of a severe epidemic of typhoid fever during last year. It is worthy of note that a similar epidemic occurred at Pisa about the same time with a mortality of 3.75 per 1,000, while at Florence it was only 1.279. According to Sir Douglas Galton, under whose superintendence these works have been carried out to a large extent, Florence only needs a more efficient system of drainage to make it the healthiest city, not only of Europe, but of the world.

PERISCOPE.

THERAPEUTICS.

THE GERM THEORY OF DIPHTHERIA FROM A THERAPEUTIC POINT OF VIEW.

According to the *Bulletin Géneral de Thérapeutique*, October 30, 1891, Dr. Jacques, of Marseilles, promulgates the following doctrine: While diphtheria is due to a specific germ from which emanate toxic properties, causing various disorders in their journey through the economy, the germ itself exists only in false membranes, and does not penetrate the blood or organs. The mouth and false membranes contain other micro-organisms beside the specific diphtheritic germ. Gargles are recommended every hour, first of perchloride of iron in solution, followed by washing the throat with warm water containing three parts boracic acid to every hundred parts water; and the alternate hour, a gargle of carbolic solution, 1 to 100, without washing the throat afterward. For very young children powders may take the place of gargles.

PROPHYLAXIS AND TREATMENT OF INFLUENZA.

Cyrus Edson, of the Health Department of the City of New York, publishes a monograph on "*La Grippe* and its Treatment." Three indications are to be fulfilled: (1) means must be taken to assist the system to rid itself of the poison to which the attack is due; (2) pain must be relieved; and, (3) not the least important, depression must be counteracted. The first indication is obtained by means of castor oil or 2 compound rhubarb pills. Three or four 3-grain powders of phenacetin are usually sufficient to relieve headache and muscular pains. Salol, 2½ grains to each dose, may be added to the phenacetin with advantage. He deprecates antipyrin and its congerers, which serve to augment the depression, and recommends instead Hoffman's anodyne, which is diaphoretic, diuretic, and stimulant. To overcome depression during and after the disease, he recommends the free use of tonics. He repeats Professor Laffont's (of Lille) recommendation of coca preparations, those of Mariani being given the preference. During the disease a hot grog, one-third Mariani wine of coca and two-thirds sweetened water, is administered, taken very hot, several times a day, the slight diaphoresis induced being a valuable addition to the tonic.

Edson considers champagne, generous wines, tonic doses of quinine, iron and strychnia also of value. The catarrhal irritation of the air-passages are best allayed by inhalations of compound tincture of benzoin. Chloroform liniment is recommended as a rubefacient; opium and carbonate of ammonia for the cough. The treatment of pneumonic *grippe* is essentially the same as that of uncomplicated pneumonia, the author emphasizing the advisability of preserving the strength of the patients.

TREATMENT OF ACUTE CORYZA.

Capitan, in *Médicine Moderne*, No. 46, 1891, recommends the following powder, which, he says, arrests generally, almost immediately, a commencing coryza, if from the very onset the patient takes pains to snuff up a pinch into each nostril, and draw it in deeply:

℞ Salol..... 1 gramme
Salicylic acid.....20 centigrammes,
Tannin.....10 "
Powdered boric acid..... 4 grammes. M.

Take a pinch every hour for half a day, and then discontinue the use of this snuff, for if it be persevered with it may cause an eczematous eruption on the margins of the nostrils from the action of the phenic acid formed from decomposition of the salol.

Another snuff-powder by the same writer is recommended as being similar in its action to the preceding, but less powerful:

℞ Powder of talc..... 5 grammes,
Antipyrine..... 1 "
Pulv. boracic acid..... 2 "
Salicylic acid.....25 centigrammes. M.

This powder may be snuffed up the nostrils without fear of irritation.

M. Tessier, in the *Annales de Médicine*, indicates several formulæ for the treatment of this affection. The following is a mixture for inhalation:

℞ Acid carbolic fort..... 5 grammes,
Liquor ammon. fort ..... 5 "
Water..... ...15 "
Alcohol.....15 " M.

Pour a few drops on blotting paper and inhale for a few seconds. In some cases, chloroform or tincture of camphor may be advantageously substituted for the water in the above.

Dobson, in the *Lancet*, May 31, 1884, advises respiration of camphor coarsely powdered and placed in a jug of boiling water as an effective remedy against coryza. "About one drachm of camphor should be added to half a pint of fluid, and the steam thus impregnated should be inhaled slowly ten minutes every hour, repeating it three or four

times, when the nasal inflammation will be much relieved. The jug containing the water as well as the face of the patient must be surrounded with a paper cone during the period of inhalation.

The following formula is recommended by Dr. Beverley Robinson:

℞ Pulv. fol. belladonnæ..... .....ʒ i.
Pulv. morph. sulph.....gr. ij.
Pulv. gum acaciæ, ad .....ʒ ss. M.
Sig. Use with the powder-blower for anterior and posterior nares.

This powder should be blown through the nose both anteriorly and posteriorly so as to coat over the mucous membrane lining the nasal passages very thoroughly. "Its most noticeable action is to diminish the congested condition of the interior of the nose, so as to permit freer passage of the inspired and expired current of air. This it does, doubtless, by contracting the small blood-vessels and lessening the amount of watery fluid which exudes from them into the cellular structure. Besides all three agents, morphia, belladonna and gum are decidedly antiphlogistic in their action upon the inflamed pituitary."

Dr. Morell Mackenzie advises the following snuff, which is to be used from the commencement of the cold, but never longer than twenty-four hours:

℞ Morph. sulph.....12 centigrammes,
Subnitrate of bismuth.....3 gr. 50. M.

To conclude: A person who is conscious of having taken a cold in the head should take his room and resort for relief to some one of the measures of local treatment above given. For internal medication we do not think that much confidence is to be placed in the small doses of atropine or the larger doses of quinine advised by some authorities. If there be a furred tongue and a deranged state of the *primæ viæ*, a saline laxative, a full dose of rhubarb and soda, or even a cholagogue cathartic may be indicated. Hourly doses (one drop) of tincture of aconite may be given, or two or three five-grain doses of acetanilid two hours apart, or two ten-grain doses of phenacetin at the same or a longer interval, if there be considerable fever and headache. It is worse than useless to take any other nourishment than a little hot liquid food till the acute symptoms have somewhat subsided. General diaphoresis will seldom be advisable for a simple coryza. Dover's powder is apt to disturb the stomach and constipate, and can seldom be required. Antimonials, jaborandi and pilocarpine are not to be thought of. A teaspoonful every two hours of aromatic spirits of ammonia can do no harm; or two or three drops of the liquor morph. sulph. along with two and a half grains of ammonium carbonate every hour for six hours, and afterwards every hour and a half. According to Phillips, a few drops of the tincture of euphrasia officinalis (eye-bright) taken at the beginning of the attack of acute coryza, and repeated every two or three hours will often abort it, and this treatment is endorsed by Dr. G. M. Garland.—*Boston Med. Surg. Jour.*

DUBOISIN AS A SEDATIVE AND HYPNOTIC.

Dr. Ostermayer (*Allgemeine Zeitschrift für Psych.*) regards the sulphate of duboisin as superior to hyoscine, in not having the inconveniences of the latter drug. It is chiefly a hypnotic, producing sleep in from twenty to thirty minutes, and is to be given in doses varying from one to three milligrammes, according to the character of the case. It is said to produce no dangerous or disagreeable symptoms, and although continuous use produces tolerance, by leaving it off for a short time the full effect can be obtained.—*Lancet.*

COPAIBA BALSAM AS A DIURETIC.

Following up Obolensky's researches on the diuretic effect of balsam of copaiba (see Supplement, August 8th, 1891, p. 45), M. I. Svetükhin (*Vratch*, No. 35, 1891) has come to the following conclusions: 1. Copaiba balsam undoubtedly has a very powerful diuretic action. 2. It induces an abundant diuresis not only in cases in which the daily quantity of the urine has previously been subnormal, but even where the quantity has been oscillating within normal limits. 3. The remedy is equally reliable in cases of cardiac, hepatic, and renal diseases, as well as in arterio-sclerosis and serous pleurisy. 4. Under the influence of the drug serous pleuritic effusions are rapidly absorbed. 5. Neither the arterial tension nor the pulse curve shows any alteration. 6. The diuretic effects are usually obtained even on the administration of 5-grain doses thrice daily; 10-grain doses, given three or four times a day, should be regarded as medium ones; 10 or 15-grain doses, given every two hours, as large ones. 7. Neither the small nor the medium doses ever give rise to gastro-intestinal disturbance or renal irritation. If albuminuria is present they never increase the proportion of albumen in the urine. 8. Given by intravenous injection to healthy dogs, copaiba balsam augments the daily quantity of the urine, but has no effect on the blood pressure.—*Brit. Med. Jour.*

MEDICINE.

CATGUT INFECTION IN THE DRY TREATMENT OF WOUNDS.

Brunner, in *Langenbeck's Archives*, Bd. 42, Heft III, replies to the article of P. Klemm, in the same journal, Bd. 41, which was abstracted in the July issue of the *University Medical Magizine*. He says the conclusions of Klemm are in direct opposition to those he himself had submitted in the *Beiträge zur klinische Chirurgie*, Bd. 6, Heft I. Klemm favored the use of silk, and argued against the asepticity of catgut, quoting the remarks of Bazzini and Biondi at the Italian Surgical Congress in his support. The author cites Novaro, Postempski and Bonnano as upholding his views at the same meeting, particularly the latter, and says that when suppuration occurs in the track of a deep catgut suturé it soon stops with absorption of the suture, but if silk is used it persists until the thread is removed. Both silk and catgut, when buried in the tissues, produce a local disturbance favoring the development of organisms, but the catgut less than the silk, because it remains there a shorter time. Such infection, when it occurs, he attributes to outside sources and not to the catgut itself. Klemm claimed that his experiments showed that silk sutures were less liable to provoke suppuration than catgut ones. To this Brunner replies that the experiments were too few in number, and recalls the failures of Lister, Socin, Mosetig, Kocher and nine other operators with silk ligatures; also, the report on its use in Billroth's clinic by Von Eiselberg to the same effect. That catgut, as a rule, heals readily in deep wounds has been too often demonstrated by experiments to be overthrown by the four experiment of Klemm. The twenty experiments in which the author buried catgut which had been infected with the germs of splenic fever, and then sterilized, were not noticed by Klemm. Catgut has been used in the Zurich clinic for ten years with good results. Socin gives twenty-three cases of extirpation of goitre in which buried catgut sutures were frequently used with perfect satisfaction; also, Kappeler writes that he, too, has good results in its use. Brunner concludes as follows: Any method of wound treatment which does not preserve the sterile catgut from secondary infection is inefficient, and all the more so if drainage is dispensed with; if lack of proper disinfection of the catgut is such a cause of failure as Klemm holds, then we ought to have them occurring as a rule and not the exception. Catgut will retain its place in surgery along with silk, but it should only be used after being thoroughly soaked in an efficient disinfectant, and not employed when simply sterilized by heat alone.—*Univ. Med. Mag.*

PATHOLOGY OF PROTEIDS.

S. Martin (*Brit. Med. Jour.*, January 1, 1891; *Jour. Chem. Soc.*, 60, 761). The changes in structure that occur in a diseased tissue or organ are associated with chemical changes, and it is to certain changes in the proteids, the most abundant constituent of most living structures, that attention was chiefly directed in the present research; although peptones and albumoses are found in the alimentary canal, their presence elsewhere in the body is pathological, as during normal absorption they are regenerated into the blood proteids. The action of microörganisms during putrefaction is, first, similar to that of pepsin, namely: it forms albumoses and peptones, but, subsequently, ptomaines may make their appearance. Putrefaction (using the word in the wide sense of the changes due to microbes) is, moreover, a frequent factor in pathological processes, and albumoses and peptones are poisonous substances. If these poisons are found in decomposing collections of cells, as in abscesses, empyema, phthisis, etc., they pass into the lymph and blood-streams, passing ultimately from the body by the urine, constituting what is generally termed peptonuria, but which should be more properly called albumosuria, the proteid which is present being deutero-albumose; Illustrative cases are cited which show the amount of albumose in the pus and in the urine before and after the evacuation of the abscess, the albumose in the urine varying with the amount of accumulated pus.

One of the most striking features of pus-formation which is common to it and albumose poisoning is fever. It is possible that other factors have also to be considered; thus leucine, often found in pus, is a fever producer; alkaloids, if they do exist, have yet to be isolated.

In ordinary pus, the agent which forms the albumoses is probably not an euzyme, but the *staphylococcus pyogenes aureus;* in tubercle, it may be the tubercle bacillus.

But the presence of albumoses in disease cannot always be ascribed to microörganisms, as in glycosuria and osteomalacia. In osteomalacia the diseased bones contain an albumose similar to that execreted in the urine, and, perhaps, due to the rapid breaking down of lowly organized cells. In the

puerperal state, the origin of the albumose may be the degenerating cells of the hypertrophied uterus which is undergoing involution. The origin of albumoses in other cases, such as measles, is at present involved in obscurity.

NEURASTHENIA AND VARICOCELE.

Dr. Wiederhold has observed quite a number of cases of neurasthenia which were evidently caused by varicocele, since treatment directed toward the latter disease effected such a marked improvement of the neurasthenia as was not observed to follow the treatment of neurasthenia uncomplicated by varicocele.

The cases of neurasthenia accompanied by varicocele were divided into two groups:

The first group was characterized by decreased mental powers. The patients (mostly young adults not particularly given to excesses) suddenly broke down at a time when their mental powers were taxed a little more than usual. They would sit for hours before an open book without comprehending what they were mechanically reading. Their physical powers were also much impaired, even the slightest exertion causing great fatigue. The sexual organs exhibited signs of irritable weakness. They were almost always excited, while coitus was impeded on account of premature ejaculation or incomplete erection.

Accompanying the above symptoms was great mental depression and despondency, leading at times to thoughts of suicide.

In another group of cases the psychical symptoms were less marked, while symptoms referred to the periphery of the nerves were prominent. Neuralgias, especially of the intercostal nerves, were frequent. Other symptoms were irregular heat, dyspepsia, paræsthesia, deafness, a feeling of heat or cold in particular limbs, increased sweating on the side of the body on which the varicocele was located.

The treatment, directed towards the varicocele which effected such prompt amelioration of the neurasthenia, consisted of electricity, hydrotherapy, and mechanical support by means of a suspensory. Surgical means were altogether omitted as the patients were treated in a hospital for nervous diseases.

The treatment employed is supposed to have relieved the varicocele by restoring the tone of the dilated veins.—*Deut. Med. Woch.*

Have sick room well lighted—sun light.

SURGERY.

COCAINE ANÆSTHESIA FOR ENUCLEATION OF THE EYE.

Dr. Edward Jackson, in an article in the *Annals of Ophthalmology*, says: While cocainization has replaced general anæsthesia for the great majority of the operations done in opththalmic practice, the limits of its usefulness in that indicated by the heading of this paper are not entirely settled. Probably most surgeons regard enucleation of the eye as always calling for the use of a general anæsthetic, but a few report that they do the operation with the aid of cocaine anæsthesia alone.

The writer's experience in this direction began with the attempted enucleation of an eye long blind, containing a foreign body, and which had become violently inflamed a few weeks before, and had caused sympathetic irritation in the other eye. A four per cent. solution of cocaine of proved efficiency was freely instilled in the conjunctival sac, and then injected into the orbital tissues with a hypodermic syringe with a freedom that would now be considered dangerous. The patient was a strong young laboring man, and the operation carried forward as rapidly as possible; but the evidently intense suffering of the patient led to the completion of the enucleation under chloroform.

This was in the early weeks of our acquaintance with cocaine as an anæsthetic, and the one experience led the writer not to make a second attempt for some years. As we became more familiar with the effects of the drug, however, it was noticed that its power of producing insensibility was very slight when the tissues to which it was applied were actively hyperæmic or inflamed; and the idea occurred to the writer that probably this was the explanation of the failure in the above case. Its very satisfactory influence for tenotomy or advanced operations made it seem probable that with the tissues in a similar condition of freedom from hyperæmia it should answer for the enucleation of the globe. A patient requiring the enucleation of a globe quite free from hyperæmia, and desirous of avoiding the use of ether, offered the opportunity for another trial. In this case the result was perfectly satisfactory, there being no complaint or evidence of severe pain. Certainly the pain was less than in the average operation for advancement of tendon.

From that time the writer has used cocaine for the enucleation of all eyes free from

hyperæmia, and has encountered but little more difficulty and caused but little more suffering than attends an ordinary squint operation. For the enucleation of hyperæmic eyes, which are a majority of those requiring enucleation, the use of ether is still resorted to.

For enucleation, cocaine is to used very much the same as for an advancement, but more freely. A four per cent. solution is instilled freely into the conjunctival sac at intervals of two or three minutes, for fifteen or twenty minutes before the operation is commenced. During the operation the cut tissues may also be bathed with the solution, but this part of its use is comparatively unimportant. No attempt is made to inject it in the deeper tissues. The most painful part of the operation is, as in squint operations, the dragging on the tendons of the recti muscles. And the total pain caused will depend mainly on the gentleness or rudeness exhibited in this portion of the operation.

INSTILLATIONS OF NITRATE OF SILVER IN THE TREATMENT OF EPIDIDYMITIS.

Dr. Samuel Alexander calls attention to the value of instillation of nitrate of silver in the posterior urethra to prevent recurrence of the epididymitis, and to hasten the course of the original disease. He does not claim originality in this method which he ascribes to Diday, but insists on its beneficial effects. His plan is to commence as soon as possible with the instillations. The patient is placed in bed, given a subcutaneous injection of morphine if the symptoms are very acute, and then with Keyes' modification of the Ultzman syringe an injection in given just within the membranous urethra. The strength of the solution should vary from 1 gr. to the ounce, if the symptoms are very acute, to 8 gr. to the ounce, and the injection must be repeated at intervals of 24 to 48 hours. During this treatment the testicle should be supported and poulticed with flaxseed. Later, the dry dressing of cotton-wool, vaseline, and rubber tissue covering should be employed. The injection should be made soon after the patient has passed his water, so that there may be as little secretion as possible in the urethra. The advantages as summed up by Dr. Alexander are: (1) The lessened liability to relapse. (2) The shorter coure of the disease. (3) The shortening of the duration of the accompanying urethritis, because treatment of the posterior urethra is continued during the existence of the epididymitis.—*Journal Cutaneous and Genito-Urinary Diseases*, December, 1891.

EPISTAXIS: AN EASY AND EFFECTUAL METHOD OF PLUGGING.

Dr. A. A. Philip writes in the *Lancet*: Uudoubtedly plugging the nares by aid of Bellocq's cannula is an excellent method; but occasionally, especially in country practice, Bellocq's cannula is not at hand, and some method easy, effectual, and effected by material alwasy within reach, must be resorted to. Such a method I have found in the following: A piece of old, soft, thin cotton or silk, or oiled silk, about six inches square (a piece of an old handkerchief will answer) is taken, and, by means of a probe, metal thermometer case, or pen-holder, or anything handy, is pushed centre first, "umbrella" fashion, into the nostril, the direction of pressure when the patient is sitting erect being backwards and slightly downwards. It is pushed on in this fashion until it is felt that the point of the "umbrella" is well into the cavity of the naso-pharynx. The thermometer case or probe, or whatever has been employed, is now pushed on in an upward direction and then towards the sides, so as to pull more of the "umbrella" into the naso-pharynx. The thermometer case is now withdrawn. We have now a sac lying in the nares, its closed end protruding well into the pharynx behind, and its open end protruding at the anterior opening of the nares. If it be thought necessary, and is convenient, the inside of the sac may be brushed with some household astringents, such as alum solution, turpentine, etc. A considerable quantity of cotton-wool is now, by means of the thermometer case, pushed well back to the bottom of the sac. Then the thermometer case being held firmly against the packed wool, the mouth of the sac is pulled upon, and thus its bottom with the wool packed in it is pulled forward, and forms a firm, hard plug wedged into the posterior nares. We may now pack the sac full of cotton-wool, dry or soaked in some astringent solution. The mouth of the sac may now be closed by tying it just outside the nostril with a piece of strong thread; it is then trimmed by scissors and the ends of the thread secured outside.

The above method is easier than any I know when both nostrils have to be plugged. It might be suggested to oil the cotton or silk in order to render its introduction easy and prevent it adhering to the mucous membrane, and to render it easy of removal; but I have never found any difficulty without the oil, as the blood renders the material wet and easy of introduction, while the oil does not facilitate removal, and may modify the effect of the astringents that may be used. The

plug may remain *in situ* as long as any other nose plug. In removing the plug, open the mouth of the sac, and with small dressing forceps remove the cotton-wool bit by bit; if there is bleeding simply syringe the sac with weak carbolic lotion or Condy's fluid and repack with clean cotton-wool, or wool impregnated with some antiseptic. If there is no bleeding when the wool is picked out, gently pull out the sac; or if it be adhering to the mucous membrane, syringe in a little warm water, and it may then easily be removed. This method has many advantages. (*a*) It is easy, quickly accomplished, and effectual, and the materials are to be found in every house, and, indeed, about everybody's person (I have plugged in this manner, simply using a handkerchief, one part of which I used for the sac, and the other, torn into narrow strips, in place of the cotton-wool); (*b*) no damage is done to the floor of the nose or back of the soft palate by strings, etc.; (*c*) no disagreeable hawking, coughing or vomiting takes place while the plug is introduced; (*d*) there are no disagreeable strings left hanging down the the throat, causing coughing or sickness while the plug is in; (*e*) the plug can be removed gently without any force, so that no damage is done to the mucous membrane and no return of hæmorrhage caused. I employed this method frequently when in country practice, and do so now in bleeding after operation on the nares. and have always found it to be satisfactory. As the method has been of great use to me, and as I am not aware that any one has spoken of it before, I take this opportunity of mentioning it, in the hope that it may be of use to some brother practitioner when confronted by an urgent case of epistaxis, and other means of plugging are not at hand.

Belfast.

THYROIDECTOMY IN EXOPHTHALMIC GOITRE.

Caird (*Edinburgh Medical Journal*, September, 1891), has reported the case of a man, twenty-five years old, with a large cystic goitre, palpitation, dyspnœa, dysphagia, protrusion of the eyeballs, and increased frequency of pulse, in which, a year after excision of the large cyst and the light lobe of the thyroid gland, the patient felt perfectly well, the eye no longer protruded, the pulse was less frequent than formerly, and there was no discomfort or dyspnœa.

OBSTETRICS.

PUERPERAL TETANUS.

The indications in the treatment of puerperal tetanus are threefold: (1) Local treatment for the elimination and destruction of pathogenic agents. (2) Modification of the blood which is affected by the toxine. (3) Diminution of the excito-motor power of the nervous centres. We cannot hope much from local antiseptic treatment after the appearance of the first symptoms, but this malady is unusually severe when complicated by septicemia, and in combating the latter we may perhaps diminish the intensity of the principal affection. The greatest caution is necessary in order to avoid violent dilatation of the cervix, which might induce reflex action, and thus increase the muscular spasm. Attempts hitherto made to modify the condition of the blood have been without result, but it is known that immunity from tetanus may be secured in rabbits by injecting into the blood tetanic cultures filtered and raised to a temperature of 60° C., according to Vallard's method, or by introducing terchloride of iodine under the skin, after the example of Behring and Kitasato; and it is claimed by these last observers that tetanus may be cured by the injection of blood serum obtained from animals rendered insusceptible to this disease. The single attempt made to verify this theory by Baginsky resulted unfavorably, and further experiments are rendered difficult by the large quantity of blood serum required. Opium and morphine, belladonna and atropine, chloral and chloroform, bromide of potassium, curara, nitrite of amyl, tobacco, veratrum viride, etc., have all been used in the hope of diminishing contraction and lessening the excito-motor power of the nervous centres. The rare cures reported have been achieved by varied medication, leeches, musk, valerian, warm baths, injections of turpentine, and chloral, but chloroform by inhalation has seemed most frequently beneficial, though the greatest care and skill are necessary in its administration, as the danger of asphyxia in tetanus is constant, and may be increased by chloroform itself. The inhalations must be continued for several hours in order to produce profound and prolonged narcosis. Chloral is next to chloroform in value, and one grain every hour, 10, 12, 14 grains a day may be given by the mouth if possible, or, if the trismus be too great, it may be given in 4-grain doses by enema. If the injections are not retained we may have recourse to morphine, which acts promptly, lessens pain, and induces sleep.

Prolonged warm baths, followed by wet compresses, have a sedative action, and favor elimination of the poison by the skin; but their use must be regulated by the condition of the patient, and they must be instantly given up if they seem to increase contraction. The hygienic surroundings of the patient must be carefully watched, and she must be preserved from physical and mental agitation. The body must be kept at a mild and uniform temperature, and intestinal accumulations removed by enema, though all efforts to rise must be strictly forbidden. Thirst should be assuaged, and the diet made as nourishing as possible, without attempting to open the jaws by force. Prolonged confinement to bed is advisable during convalescence, in order to avoid relapse.—*Gazette des Hôpitaux*, December 3, 1891.

PREVENTION OF MAMMARY ABSCESS.

Tarnier (*Jour. des Sages-Femmes*, December 16th, 1891), insists upon women being kept very clean in childbed. Their hands must be washed, else the nipple may be contaminated by a finger that has just touched the vulva. The nipple should be washed both before and after every act of suckling with water that has been boiled, or with a solution of boric acid. The washing must be done with clean lint or sterilized wool, and not with a sponge. The preliminary washing is necessary, as there might be microbes on the nipple, and the child's mouth might transfer them to a minute fissure, frequent on the nipple after delivery. The second washing removes from the nipple, all milk which, if left there, might become a breeding-ground for germs, and thus set up abscess, or infect the child's mouth and cause aphthæ. Professor Tarnier takes a stronger precaution in his wards. Every woman has her breasts dressed, as a preventive measure, with a compress soaked in a 1 in 5,000 sublimate solution, held in place by strapping, as the pad is likely to slip; a band of gauze is passed round the thorax and wound around the breasts, so as to envelop them completely. There were, in consequence, only two cases of abscess of the breast from November 1st, 1889, to July 15th, 1890, and in both the mammæ were, for different reasons, neglected. This application of sublimate cannot possibly hurt the fœtus. A syphilitic infant can safely take five minims of Van Swieten's solution. The equivalent of that dose in a 1 in 5,000 sublimate solution would be 25 drops, and a child suckling a breast dressed as above described could hardly swallow a trace of the mercury.—*Brit. Med. Jour.*

GYNÆCOLOGY.

GALVANISM IN PRURITUS VULVÆ.

S. S. Kholmogoroff (*Med. Obozrenië*, No. 13, 1891) has tried galvanism in an extremely severe and obstinate case of pruritis with very satisfactory results. The patient, a generally healthy and well-nourished, regularly-menstruating lady, aged 36, married twelve years, had begun to suffer from the complaint, without any assignable cause, two years previously. For the first six months or so the symptoms had appeared only a few days before each menstruation, increasing during the period, and ceasing altogether during the intercatamenial time. Later on it had become incessant, notwithstanding persevering treatment. Nothing abnormal could be seen about the internal or external genitals. The positive electrode—in the shape of a metallic cylinder insulated up to its distal tip by hard rubber—was introduced into the vagina for four or five centimetres, while the cathode— four centimetres in diameter, covered with chamois leather, and moistened with a salt solution—was placed upon the external genitals, and gradually moved over the whole of the itching area. The strength of the current varied from ten to sixteen milliampères, the duration of the sittings from ten to fifteen minutes. After six sittings the disease was completely and permanently cured.—*Brit. Med. Jour.*

AMENORRHŒA OF SCHOOL-GIRLS.

Dr. T. A. Reamy (*Cincinnati Lancet Clinic*), in discussing the amenorrhœa in anæmia, common to school-girls, says: (1) She must leave school, and must not even study at home. (2) She must spend several hours each day in the open air, either walking or riding. In winter she must of course be warmly clad, but must wear no sheepskins or other chest protecting pads. Standing in the open air, she must be induced to breathe deeply with the mouth closed; this should be done for at least fifteen or twenty minutes, and be repeated at least twice a day. Nothing that can be done will more rapidly improve the character of her blood. (3) She must sponge her extremities and body each morning on arising from bed. The water must be of the temperature of the room, and she must practise friction freely with an ordinary towel. (4) She must drink plenty of milk and eat plenty of beefsteak. (5) She must take small doses of iron, combined with some bitter tonic, three times a day. Improvement may be somewhat slow, but if

this course is faithfully carried out, a perfect cure will result, and her education may then be finished. If this course or its equivalent be not followed, the cases will go from bad to worse, and finally die from pulmonary tuberculosis.

DIFFICULTY OF LITHOTRITY IN WOMEN.

Guyon (*Ann de Gynéc.*, Oct., 1891) observes that lithotrity is far harder in women than in men. The introduction of the lithotrite is easy, but the female bladder is either too readily distended or much contracted through pain. In women there is no pouch in the lower and posterior part of the bladder as in man, so that a stone may lie in any part of the vesical cavity. In woman a pouch must be made by pressing the angle of the lithotrite downwards, so that the calculus slips down and may readily be seized and crushed. This manœuvre is easy when the bladder is healthy. When cystitis exists it is very difficult and the calculus must first be seized, then brought into the lower part of the bladder and crushed. In some cases, the stone keeps persistently in the uppermost part of the bladder and has to be crushed there. This condition seems associated with a tendency in the walls of the bladder to fall in and close like the leaves of a portfolio. The results of lithotrity are much the same in both sexes. Guyon has repeatedly seen recovery within a few days, without fever, in women after lithotrity.—*Brit. Med. Jour.*

PROLAPSE OF THE FEMALE URETHRA.

Kleinwächter says (*Zeitschrift für Geburt. und Gynäkol.*, Band. xxii., Hft. 1, 1891) the affection has always been considered a rare one, but the author, after observing two cases, investigated the literature of the subject and was able to collect about one hundred cases. This would go to show that the affection is not so very rare, but that no particular attention has been paid to it; and this is in great part due to the fact that most of the cases occur in children. The prolapse may be as large as a bean, a walnut, or even a pigeon's egg; in fact, Lawson Tait and Baehr observed cases as large as a hen's egg. The prolapsed tissue is hyperæmic, œdematous; pale-red, dark-red, or bluish-red in color; is eroded, suppurating; slightly or very painful, whether coming on suddenly or gradually, etc. The prolapse is seldom a partial one, but is usually complete. Of thirty-four cases it was complete in twenty-four and partial in ten.

PÆDIATRICS

INTUBATION IN RUSSIA.

Jakubowski's results are as follows:

1. Primary diphtheria of the larynx. In fifty-nine cases, intubation was performed in thirty-two, with twenty-one recoveries—65.6 per cent.

Tracheotomy was performed in twenty-seven cases, with two recoveries—7.4 per cent.

In five cases of secondary diphtheria, where intubation was performed, there resulted three recoveries—60 per cent.

From these results the author draws the following conclusions:

Intubation is an operation less dangerous and less difficult than tracheotomy.

2. The inconveniences of intubation are: (*a*) the patient should be under the constant charge of the physician, and (*b*) the introduction and removal of the tube provokes disagreeable symptoms.

3. Secondary pneumonias follow more often intubation than tracheotomy.

4. In croup limited to the larynx and to the superior part of the trachea intubation is the procedure necessary.

5. In a diffuse croupous inflammation of the larynx, trachea, and bronchial tubes, tracheotomy is the operation required.—*Bull. Gen. de Thèrapeutique*, December 15, 1891.

GASTRO-INTESTINAL HÆMORRHAGE IN THE NEW-BORN.

Two cases of this character are reported (*Rev. Mens. des Mal. de l'Enf.*, October, 1891), and there is also a study of certain accidental hæmorrhage with local causation. They occur in children who are usually normal in appearance, they have little or no tendency to recurrence, and may be followed by complete cure. The quantity of blood lost varies; there may be only a single discharge, or there may be several, the quantity lost being sufficient to cause death from acute anæmia, or from the weakness which follows the accident. Hæmatemesis alone rarely occurs. There is most frequently a discharge by the mouth and rectum, or by the rectum alone. In one of the author's cases, intestinal hæmorrhage occurred the day after birth, and in the other, hæmatemesis, which was followed on the next day by a large intestinal hæmorrhage. Both children recovered. These cases followed the rule that such hæmorrhages usually occur within thirty-six hours from birth. Such bleedings are probably due to new conditions of the

circulation in the walls of the stomach and intestine, the circulation being more active than during fœtal life. For treatment the author recommends a warm bath at 38° C. This was efficient in his case in which the hæmorrhage recurred.

COMPLICATIONS OF CHICKEN-POX.

Demme (*Wein med. Blätter*, Nos. 3 and 4, 1892), discusses the complications of varicella observed by him in Berne during 1890. He relates two cases in which there were very marked prodromata; in one case there was for three days high temperature, somnolence, anorexia, nausea, and, finally, a convulsive seizure; in the other, there was severe blood-stained diarrhœa, accompanied by vomiting and fever. After these symptoms had lasted eighteen hours, a copious eruption of varicella appeared, and the symptoms disappeared so quickly that in two hours and a half the temperature was normal, and in twelve hours more the child was practically convalescent. He met with two cases in which the eruptive period was unusually prolonged; in both the successive crops of pocks which appeared at intervals of three or four days were accompanied by a scarlatiniform erythema, and in both nephritis occurred as sequela. He met with two cases in which the rash became gangrenous: one, a boy, aged 2¾ years, died; the other, also a boy, aged 2 years and 2 months, recovered. The treatment in the successful case consisted of careful feeding and the application of tincture of iodine to the gangrenous spots, previously cleaned with the following modification of Lugol's solution: pure iodine 1 part, iodide of potassium 10 parts, distilled water 500 parts; finally, the part was packed with iodoform gauze. The bacteriological examination of these cases did not yield trustworthy results, and nothing was observed in either case to throw any light on the cause of the occurrence of gangrene. Demme also met with two examples of ulceration of the varicellar pocks, an event which he considers to be rare. In one case there seemed to be little room to doubt that the ulcerative process was tuberculous, the infection having taken place through the mother, who was in an advanced stage of pulmonary phthisis. The treatment adopted in this case, which was successful, consisted in a daily warm bath containing about 7½ grains of corrosive sublimate, painting of the ulcers with iodoform dissolved in ether and subsequent packing with iodoform gauze, and the internal administration of syrup of the iodide of iron.—*Brit. Med. Jour.*

HYGIENE.

BACTERIOLOGICAL EXAMINATION OF WATER.

The chief interest attached to the bacteriological examination of water, writes Professor P. A. Frankland in *Nature*, lies in its application to the hygiene of water-supply, inasmuch as it is all but certain that two at least of the most fatal zymotic diseases—cholera and typhoid—can be, and are constantly propagated through the presence of specific micro-organisms in water, and indeed the majority of the bacteriologists are agreed as to the particular forms responsible for these diseases. On this account it is conceived by many that the primary object of the bacteriological examination should be the search for such pathogenic microbes. It is obvious that if the typhoid organism could be detected with unerring certainty in any water in which it was present, a search for this bacillus in the ordinary course of water examination would still have only a very subsidiary interest. Waters are surely not only to be condemned for drinking-purposes when they contain the germs of zymotic disease at the time of analysis, but in all cases when they are subject to contaminations which may at any time contain such germs. Sewage-contaminated waters must on this account be invariably proscribed, quite irrespectively of whether the sewage is, at the time that the water is submitted to examination, derived from healthy or diseased persons. In the present state of our knowledge there can be no doubt that chemical analysis affords us in general a better, although a far from perfect, indication of sewage contamination than do the results of bacteriological examination. The real value of these bacteriological investigations, if judiciously applied, consists in their power of furnishing us with information as to the probable fate of dangerous organisms, should they gain access to drinking-water. It is by their means that we have learnt that many such organisms can preserve their vitality—nay, in some cases can actually undergo multiplication—in ordinary drinking-water; that they are destroyed by maintaining the water at the boiling point for a short time; and that they are more or less perfectly removed by some processes of filtration and precipitation, whilst other processes of the same nature are worthless, or even worse.

Strychnine is used as an antidote for snake bite in Australia.

HYOSCYAMINE IN LETTUCE.

Although preparations of lettuce have from very early times had a reputation in medicine for their soporific properties, the narcotic constituent of the plant has never been ascertained with any certainty. Various neutral, fatty, and waxy bodies separated from the milky sap of different species of Lactuca have been from time to time described as compounds of medicinal value, but on the other hand it has been denied that the dried milk-sap, lactucarium, in spite of its narcotic odor, possesses any sedative action, and in fact this preparation is no longer officinal in England or the United States. It is therefore interesting to learn in a communication from the Research Laboratory of the Pharmaceutical Society, read last week before the Clinical Society, that Mr. T. S. Dymond has established beyond doubt the presence of hyoscyamine, the principal alkaloid of belladonna and henbane, not only in the cabbage and Cos varieties of the common lettuce, L. sativa, but also in the wild lettuce, L. virosa. The amount in the young plants is certainly very minute, but in the official green extract, which according to the directions of the *Britsh Pharmacopœia* is to be prepared from the flowering herb of L. virosa, the mydriatic alkaloid occurs to the extent of 0.02 per cent. As the physiological action of the drug closely corresponds with that of hyoscyamine, there is little doubt that the sedative properties of the lettuce are due to this alkaloid; and though the quantity present in the plant during the early stages of its growth is not sufficient to restrict its consumption as a salad, the observation suggests some explanation of the serious and even fatal results recorded in cases of immoderate consumption of lettuce. It is also interesting to find an alkaloid, which has previously only been associated with the natural order Solanaceæ, as a constant constituent of a member of the Composite group, in which alkaloids have been comparatively rarely observed.—*Brit. Med. Jour.*

DIET IN FEVER.

The question of diet in fever is a most important one, and demands careful attention at the hands of the practitioner. The various metabolic changes associated with a high or raised bodily temperature, and the physiological effects which result therefrom naturally indicate that proper or improper dieting during the febrile state may be all powerful for good or emphatically harmful. A French contemporary, in discussion a new work by Mauquat, draws attention to some practical facts in connection with this subject, to which some reference may here be made. It is generally admitted that in the febrile state gastric digestion is at a low ebb, owing to the diminished secretion of gastric juice; moreover, there is a sensible deduction in one of its constituents, namely, hydrochloric acid. It is for this reasons that patients suffering from fever find acid drinks so grateful to their palates. The proportion of pepsin is not reduced, but both the pancreatic and biliary secretions are much diminished, rendering the digestion of fatty matters almost impossible. It is pointed out that eggs are very unsuitable for food in the febrile state, their digestion requiring a large amount of hydrochloric acid, which is always deficient in these cases. Meat, of course, falls into the same category. With regard to milk, its chief utility seems to be in the water and salts which it contains. If a little hydrochloric acid be added to it, its digestion would be almost assured. Farinaceous materials are well digested by fever patient, and for this reason may be administered in suitable cases. Beef tea as ordinarily made does not contain much albumen, but it is rich in salts, and is useful on these grounds. To generalize, however, beyond a certain point in regard to diet in fever would fail to be practically serviceable; each case, therefore, of fever must be treated, from a dietetic point of view, on its own merits, and the practitioner would do well to bear in mind that he has to steer a middle course course between overfeeding and under-feeding. A too low diet is obviously disadvantageous to the patient, while the other extreme is just as harmful.—*Med. Press.*

EYE LOTIONS OF BORIC ACID FOR INFLUENZA.

Dr. Richard Sisley, in a paper read before the International Congress of Hygiene and Demography in London last summer, quoted Dr. Bezly Thorne, who recommended that the eyes of people exposed to infection should be bathed with a solution of boric acid, and found that none of those who adopted that practice suffered from the disease. The recommendation was founded on the theory that the poison of influenza is absorbed by the conjunctiva.

M. Sig. ʒ j three times a day, after meals, in a wineglassful of water.

MEDICAL CHEMISTRY.

EFFECT OF HEAT ON CHLORALAMIDE.

It is a common practice in making aqueous solutions of chloralamide to hasten the process by the aid of heat. It is pointed out (*Therap. Monatsh.*) that this drug decomposes when its temperature is raised to over 60° C. Hence the solution should always be prepared in the cold way.

ARSENICAL COD-LIVER OIL.

Arsenical cod-liver oil, upon the request of a specialist in children's diseases, was prepared as follows: 0.5 gm. arsenious oxide was warmed with 20 grams absolute alcohol in a small flask; no solution took place until a small particle of potassium carbonate was added, when the oxide immediately dissolved without dissolving the potassium carbonate; after filtering, the solution was added to 1,500 grams cod-liver oil, and warmed on a water-bath until the alcohol was dissipated. The oil is perfectly transparent, and holds arsenious oxide in solution; 30 grams of the preparation contain 5 mg. arsenious oxide [this is not correct if the arsenious oxide be completely dissolved; 30 grams will then contain 10 mg.—F. X. M.] and can be given to children in doses of ½—1 teaspoonful.—A. Janssen, *Pharm. Ztg.*, 1891, 780.

SOLUTOL AND SOLVEOL, TWO NEW DISINFECTANTS.

The firm of "Dr. F. von Heyden Nachfolger" in Radebeul, near Dresden, the original manufacturers of salicylic acid under Kolbe's now expired patent, have put on the market a soluble form of cresol under the name *solutol*. The solubility of cresol is brought about by the pressure of cresol-sodium. The preparation contains, in 100 cc., 60.4 gr. of cresol, one-fourth of it in a free state, and the remainder as cresol-sodium.

Solutol has been found to be a most efficient disinfectant for general domestic or hospital purposes, such as sinks and water-closets, infected clothing, sputa of consumptives, etc., and an excellent preservative of dead bodies.

It is suitable for medical or surgical disinfection, owing to its strongly alkaline character.

Solveol, on the other hand, is a disinfectant and antiseptic specially designed for surgical purposes. In this the solution of cresol is brought about by the presence of sodium cresotate. The compound is soluble in water to a perfectly clear liquid, which, while much more efficient than carbolic acid, is at the same time much less poisonous.

For medical or surgical purposes the most suitable strength of solution is:

Solveol	27 cc.
Water	to make 2,000 "

For disinfecting the air in sick-rooms, by spraying, 37 cc. of solveol should be dissolved in 480 cc. of water.—After *Zeitschr. d. Oest. Ap. Ver.*, December 10th.

THE ALKALOIDAL VARIABILITY OF OPIUM.

Nearly all the published criticism regarding opium chiefly refers to the percentage of morphine, little attention being paid to the amount of narcotine present. We are, therefore, pleased to notice that M. Adrian has published (*Nouv. Remed.*) the results of thirty-eight assays made at his pharmaceutical factory during the past few years. With two exceptions all the samples showed above seven per cent. of morphine, the average being ten per cent., while the average narcotine content was 2.5 per cent. The average in the latter case gives little idea of the variation actually present, so we quote a few of the figures:

Morphine	Narcotine	Morphine	Narcotine
10.21	2.947	9.00	0.50
11.00	3.343	12.065	3.05
8.066	1.833	8.50	1.90
10.515	3.85	8.48	3.49
8.35	.52	9.203	3.906
9.208	1.555	7.51	.76
12.15	.25	6.75	2.30
11.666	2.025	3.875	3.45

The method of assay is not mentioned, but the want of that information does not detract from the value of these figures so far as comparison is concerned, and they suffice to explain how some preparations cause little or no headache, while others give intense dissatisfaction.

FATAL HÆMORRHAGE FROM SCARIFICATION OF THE CONJUNCTIVA.

Shirley (*New York Medical Journal*, 1892, lv, 1, p. 15) has recorded the case of a mulatto infant, six weeks old, with hereditary syphilis, in which fatal hæmorrhage followed scarification of the palpebral conjunctiva for purulent conjunctivitis. Hot water, ice, and styptics failing to restrain the hæmorrhage, sutures were passed beneath the bleeding surfaces and the upper and lower lids were united. The hæmorrhage was controlled, but the child died.

NEWS AND MISCELLANY.

CHIROGRAPHY AND MERIT.

It is related of the late Sir Richard Quain, whose handwriting was execrable, that when a student he once went up for an examination, in which he confidently expected to take the prize. However, the medal was given to somebody else, and on inquiry it was found that his writing was so bad that the examiner had been able to read only one of the answers.

MORPHINOMANIACS AND HYPODERMIC SYRINGES.

Owing to the recent publication of a case of death after injection of a small amount of cocaine into the tunica vaginalis, there have been numerous articles in the French medical papers on the entire question of injections of powerful solutions. M. Verneuil has shown that the much-vaunted hypodermic injections of antipyrin have proved of more harm than good; They often fail to cure neuralgia, lumbago, etc., and always cause pain, not infrequently complicated with wide ecchymoses, œdema, lymphangitis, and neuritis. These dangers may be avoided if only weak solutions and clean syringes be used, but there is no doubt that there can be but one opinion on the use of unprescribed hypodermic injections by the general public. Last summer, when traveling in a railway carriage in the South of France, an English medical man heard a middle-aged lady proudly boast that she had a *névrose* which could only be assuaged by frequent hypodermic injections of morphine. She then raised her skirt so as to expose the bare skin of the thigh immediately above the stocking, and gravely injected a syringeful of morphine, giving her fellow-passengers, who listened with intense interest, a long account of the subjective symptoms that would follow. The *Gazette Hebdomadaire de Médecine* asks if legislation is not needed to forbid druggists and instrument makers from selling dangerous solutions and hypodermic syringes direct to persons who employ morphine, etc., without medical advice.—*Brit. Med. Jour.*

INTERNATIONAL PERIODICAL CONGRESS OF GYNÆCOLOGY AND OBSTETRICS.

The Belgian Society of Gynæcology and Obstetrics, under the patronage of the Belgian Government, has taken the initiative in organizing "The International Periodical Congress of Gynæcology and Obstetrics," the first session of which will be held in Brussels, September 14 to 19 inclusive, 1892. Three leading questions will be offered for discussion:

1st. Pelvic Suppurations; Referee, Dr. Paul Segond, Paris.

2d. Extra Uterine Pregnancy; Referee, Dr. A Martin, Berlin.

3d. Placenta Prævia; Referee, Dr. Berry Hart, Edinburg.

Fees: Members participating in the first session, 30 francs. (This will entitle the holder to a copy of the proceedings of the Congress.)

Founders (Life Membership), 300 francs.

In the connection with the Congress there will be an International Exposition of instruments and appliances, pertaining to Gynæcology and Obstetrics.

All communications pertaining to this Congress should be mailed direct to the American Secretary, who will promptly furnish all information. All notifications to be forwarded should be received by August 1st.

Everything points to a great success in this Congress. Though notices concerning it have been rather late in this country, already men of celebrity have promised to visit and contribute papers. Among the many foreigners who have written to the Secretary General endorsing and promising support to the undertaking, may be mentioned the following eminent men:

Belgium.—De Roubaix, Sacre, Mirriar, Pigeolot, Charles, Sanpart, and others.

Italy.—Porro, La Torre, Mangiazalli, Bozzi, Morisain.

Turkey.—Chatazian.

France.—Pean, Demous, Fochier, Auvard, Doleris, Pozzi, Tarnier, Budin, Terrillon, Terrier, and others.

Holland.—Stokvis, Treub, Nyhoff.

England.—Lawson Tait, Wm. Priestly, Champneys, F. Elder, J. White, Watt Black, Thornton, Doran, Specer Wells, Bantock, and others.

Austria.—Pawlik, Albert, Chrobuk.

Germany.—Martin, Leopold, Sanger, Gusserow, Veit, Winckel, Hegar, Kaltenbach, Freund, Heyder, and others.

Finland.—Engstrom, Heinricius, Pippingohold.

Switzerland.—Reverdin, Vuillet.

Russia.—Slaviansky.

Sweden.—Saliss, Westernark,

Norway.—Statfeldt, Howitz, Meyer.

Further details will be furnished as soon as received.

SULFONAL-BAYER.

Sulfonal-Bayer is a "pure hypnotic" because it gives a purely hypnotic action and produces no other effect. It is a "true nerve sedative" because its action continues after the remedy is discontinued. Sulfonal is used in all Insomnias, Insanity, and in all cases in which hypnotics are indicated. It is a *safe remedy*, and it does not give rise to a drug habit. Very reliable and effective, its action is slower than that of the narcotics ; hence, care must be taken to give it as directed. It is supplied in ounces; also in tablets and pills.

ARISTOL.

In all Ulcerations, Skin Diseases, Lesions of the Eye, Ear, Nose, Mouth and other cavities ; in Dysentary, Gonorrhœa, Ivy-poisoning, Burns, Scalds, Blisters and all external traumatisms, Aristol has shown itself to be a safe and effective remedy. It is also given (hypodermically), in Phthisis. It is used in ointments, powders, crayons, suppositories, oils, sprays, collodions, tampons, bandages, etc. Aristol Gauze is now widely used *in the place of Iodoform Gauze*, so long offensive to physicians. Aristol is supplied in ounces only.

DESCRIPTIVE PAMPHLETS FORWARDED ON APPLICATION.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

CLINICAL LECTURE.

CARDIAC GRIPPE.*

By H. HUCHARD. M. D.,
OF PARIS, FRANCE.

Gentlemen: At this time the grippe constitutes a current topic of study. The malady attacks everybody indiscriminately, but not in the same manner. As far back as 1691, Wepfer said of this affection that it was a true Proteus, because of its assuming in its manifestations all manner of interesting forms. Of these we shall to-day examine only the cardiac and vascular phenomena.

Epidemics of the grippe do not belong to recent times, for we know that during the years of 1239 and 1311 the disease exercised a deleterious influence over Europe. It was, however, during the epidemic of 1580 that it spread over Europe its disastrous ravages. G. Henish, of Saxe, spoke then, for the first time, of this disorder as attacking the præcordial region, producing palpitations and a small, irregular and accelerated pulse. Still later, in 1709, there were found at autopsies polypoid concretions of the great venous trunks of the heart. It was noticed also, in 1729, by various authors, that the disease produced syncope and præcordial distress. Beccaria, of Bologna, in 1730 asserted in a most categorical manner, that in this affection "pain existed over the region of the heart, the pulse being, at first, compressible and uneven, and afterwards, in the progress of the malady, it became large, full, hard, and frequent or hard and uneven." A great number of sudden deaths were reported at Edinburgh in 1732, and by Saillant in 1775. During the epidemic of Silesia, in 1736, intense pains of a lancinating character were observed to occur over the præcordial region. In 1743 Ludwig Huckel observed lipothymies and a small and accelerated pulse. Finally, in 1800, Gilibert called attention to a rapid, weak pulse, almost filiform, accompanied with more or less prolonged distress over the region of the heart.

You see, therefore, that the cardiac troubles produced by the grippe have been known for a long time back; but not all the symptoms of this nature were previously observed, either because the classification of such symptoms was a defective one or because the disease did not remain long enough for the heart and the vessels to become affected during its course or after the establishment of a cure. This lecture, in which I will try to record my personal observations and those of other authors, will be devoted to the discussion of the subject from the interesting point of view referred to. I will endeavor to show you that during an attack of influenza the heart and the blood-vessels may become equally affected. We have, therefore, to study *cardiac* and *vascular grippe.*

1. *Cardiac Grippe.*—Any of the constituent parts of the heart may be affected: the pericardium, the endocardium, the myocardium, and, finally, the nervous mechanism itself.

a. Grippal Pericarditis.—We made, the day before yesterday, an autopsy on a very interesting patient. After presenting during life the symptoms of a grippal pneumonia followed by those of a meta-pneumonic purulent pleurisy, our attention was called to the heart, owing to the manifest signs of pericarditis, probably of a secondary nature, and due to the propagation of the pleuro-pulmonary inflammation. Albumen was abundantly found in the urine; the tongue was dry; the adynamic condition quite marked; and the patient died at the time when the question of empyema was being discussed. The *post-mortem* confirmed our diagnosis; it revealed an abundant purulent pleural effusion on the left side, accompanied with atelectasis of the lung; a dry pericardium with numerous adhesions, and a myocarditis which will be confirmed, undoubtedly, by microscopical examination.

*A clinical lecture delivered at the "Hôpital Bichat."

Here we have, therefore, first an attack of the grippe, followed by *pneumonia* and *pleurisy*, and, finally by *pericarditis*, undoubtedly secondary to the pleurisy. This is not always what happens in such cases, for purulent pericarditis has been observed at the very onset. Such, however, is not of frequent occurrence.

Grippal pericarditis has been noticed by other authors. Fereol (*Soc. Med. des hôpit.*, February 21, 1890) has spoken of "a distressing dyspnœa resembling that occurring in certain forms of myocarditis," and asserts to have observed four cases of pericarditis during the epidemic of 1889–1890. Menetrier, in his remarkable thesis of 1886, affirms that pericarditis is so frequent in the course of grippal pneumonia, that it may be latent, and refers to two observations of his own, to one of Bucquoy and to three others of Cornil (*Jour. des conn. méd.*, 1886), in all of which there were found, at the autopsy, abundant false fibrinous membranes on the pericardium, without a single symptom or sign having been recognized during life. On the other hand, pericarditis may be diagnosed, as in the case we have mentioned. Jaccoud has reported an instance in which there were developed phenomena of cardiac asthenia, phenomena which, according to this author, lead quite frequently to a fatal termination.

In fact, the gravity of grippal pericarditis is due to two principal causes: its frequent complication with myocarditis, and its purulent nature. In the first instance, inflammation of the pericardium is due most generally to pneumococci and is nearly always secondary to a pleuro-pneumonia. Thus Grasset (*Montpellier Médical*, 1890) has seen a case of pericarditis from which were removed 700 grammes of a dirty, greenish, thick and homogeneous liquid, accompanying a true pleural abscess. Very rarely is a pneumococcic purulent pericarditis of a primary nature, that is to say, independent of all local lesion in the lung or pleura. A pneumococcic pericarditis is, in fact, like certain forms of endocarditis, indirectly produced by the grippe, and ought to be considered as a complication of this malady. The proof of this assertion lies in the fact that other microbes, such as staphylococci and streptococci may similarly be found in the purulent liquids.

Grippal pericarditis is, nevertheless, not ordinarily of a purulent nature; you will find some cases in which the liquid is serous or hæmorrhagic, as I have observed in two instances. Most generally the pericarditis is dry, there being but little liquid of a pale yellow color, as is similarly found in cases of purulent pleurisy or in pneumonias which have terminated by gray hepatization. At all events, it is a complication which claims our attention and must be closely studied in order to recognize it.

(*b*) *Grippal endocarditis.*—In the febrile infectious diseases endocarditis may be of two kinds: on the one hand, it may be simply infectious without being contagious, infectious because it is due to the presence of bacteria; non-contagious, because it is localized in its effects and is not disseminated through the action of the micro-organisms. Then, again, it may be both infectious and contagious at the same time, causing throughout the circulation the most serious general symptoms.

Cases of the first kind have been reported, but they are rare. They occur generally in persons subject to old valvular lesions, in whom the slightest cause may produce the condition referred to. Thus a chronic endocarditis may be the cause of the acute form. Similarly, a lesion of the valvular orifice, which has been for a long time in a latent condition, may be so influenced by the grippe as to produce the most serious symptoms. In reference to this point Stokes in 1840 reported the following case:

A man of middle age, apparently healthy but far advanced in the inflammatory disease in question, was attacked by the grippe. Under its influence it was found for the first time that the heart became susceptible of the most extraordinary irritation. The violent and tumultuous action of the organ could be perceived over a large portion of the chest, and was accompanied at the same time by a murmur which occurred during the first sound. For three or four days the patient appeared well, but he died suddenly. At the autopsy, there was found calcareous deposits on the aortic orifice which so obstructed this, that it seemed at first sight as if the opening were entirely closed. There was, in fact, only a very small aperture through which only a fine probe could be introduced. This man never exhibited during life any symptoms of cardiac trouble, and it is possible, according to Stokes, that, owing to the extraordinary size of the deposits, the affection was not recognized during a more or less calm condition of the heart. Thus, in this patient the symptoms of cardiac disease were made apparent through the action of the grippal attack. The heart was disturbed in its action, which proves, on the whole, that the painful sufferings experienced in the course of a disease depend, within certain

limits, at least, more upon the vital than upon the physical condition of the organs.

Graves has reported a similar case relative to a large obstruction of the aortic orifice (complete ossification of the aortic valves and sinuses, accompanied with retraction of the opening). This patient, who had not exhibited any heart trouble, was, six months before, suddenly attacked with symptoms of distress on going up a hill. A month before death he had the grippe, and consulted Graves. At that time a murmur was detected, occurring during the first sound of the heart. He had bronchitis, and suffered from cough and attacks of asthma. These symptoms progressed rapidly; orthopnœa and dropsy were increased, and death overtook the patient in a short time. Here, according to Graves, two causes contributed to diminish the vitality of the heart and hasten a fatal issue: the efforts of the patient in climbing the hill and the invasion of influenza.

Primary, simple endocarditis may give rise, after an attack of the grippe, to permanent lesions of the orifices. This must be rare, however, judging from my personal observations and especially from the fact that authors are silent in this respect. Nevertheles, Rochoux some time ago referred to a case of a woman, 28 years of age, who, after an attack of influenza, suffered from palpitation, oppressiveness, pulmonary œdema, with signs of stenosis of the left auriculo-ventricular opening, a lesion which was verified at the autopsy. The question arises, however, whether the mitral stenosis did not exist previously, and was only aggravated by the grippal affection.

In regard to the infectio-contagious endocarditis (ulcero-vegetating endocarditis), this has been observed during the course, or in the convalescing period of the grippe, being developed not only in a previously affected endocardium but also in a healthy one. The following case is reported by Oulmont and Barbier (*Médecine Moderne*, July 9, 1891):

A woman, 34 years of age, was attacked by influenza in November, 1890, and soon after exhibited symptoms of pericarditis and of mitral and aortic endocarditis (systolic murmur at the apex and base of the heart). She died on the 6th of February. 1891, with typhoid symptoms. At the *post-mortem* there was found a slight pericarditis accompanied with small points of ecchymosis disseminated over the visceral pericardium, and a small amount of a reddish serous liquid in the pericardial sac. Surrounding the left auriculo-ventricular opening there were found small vegetations, especially over the large leaflet of the mitral valve, the small leaflet having been transformed into a cauliflower vegetation of the size of a cherry. Under a fibrinous mass a little valve was discovered, roughened and covered with vegetations, some of these being in an ulcerated condition. At the aortic orifice the valves, posteriorly and anteriorly, presented a roughened appearance, with a few irregular nodules. All these parts were in a reddened condition. The aorta was intact. Bacteriological examination revealed a streptococcic endocarditis.

Flessinger, of Oyonnax, (*Gazette Méd. de Paris*, September 2, 1891) reports the case of a child, four years of age, in which, on the 17th day of influenza, a mitral endocarditis was detected, a dull murmur occurring during the systole and diastole, being communicated as far as the axilla. The child died seven days after with pronounced cardiac symptoms, such as cyanosis, coldness of the extremities, etc. No autopsy was made.

You will also find many cases of infectious grippal endocarditis, of both a benign and malignant nature, reported in a work of Pawinski (*Berl. klin. Wochen.*, 1891, Nos. 28, 29 and 30). Finally, G. See (*Acad. de Méd.*, April 19, 1890) asserts to have observed cases of endocarditis resembling pyæmia. On *post-mortem* streptococci were found in the vegetations.

At the recent Congress of Marseilles (*Congrès de Marseille*, Sept. 21, 1891, I reported two analogous cases, and, especially, one of vegetative endocarditis due to pneumococci over the aortic orifice. This was that of a patient who had suffered for a long time previously with chronic aortitis without murmur, but in whom, after a very serious attack of grippal pneumonia, there was rapidly developed a pronounced systolic murmur with all the symptoms of an infectious endocarditis. The autopsy confirmed the diagnosis. I have seen two other similar cases, with the difference that in these instances the endocarditis affected in a sudden manner a sound heart. In these two cases the lesions invaded especially the aortic orifices.

Other cases of the same nature have been observed, and during the epidemic of 1886, Ménetier found the endocardial complication to be of a comparatively frequent occurrence, having met with it seven times at L'Hôpital de la Pitié. In these instances there was found a vegetating endocarditis of the tricuspid valve, in addition to old mitral lesions.

I must still cite the following observation: one of Lanceraux (*Soc. Anat.*, April 2, 1886) relative to a vegetating endocarditis of the

mitral and aortic orifices; one of Brourdel (Mémoire de Netter, *Arch. de Physiol.*, 1886) which was a case of aortic ulcerated endocarditis occurring in a patient suffering from old mitral lesions; and still a third reported by Hanot (*Arch. de Méd.*, 1886) which consisted of a suppurative pneumonia, accompanied with recent endocarditis of the aorta and suppurative meningitis and diplococci in the exudate. This last one, apparently of a complex character, occurred in a patient who, after the defervescence of a pneumonia of the base of the left lung, was attacked by delirium for six days, followed by right hemiplegia accompanied with endocarditis, this being characterized during life by a marked systolic murmur.

In the majority of these cases there has been found in the depth of the vegetations the same pathogenic germ, that is, the same as that causing pneumonia. The seat of the endocarditis is generally at the aortic orifice and is rarely accompanied with emboli owing to the peculiar disposition of the vegetations. Infectious pneumococcic endocarditis appears chiefly in two forms: In the first place, it may occur conjointly with pneumonia, but in this instance it is not easily recognized, since its symptomatology is shrouded, so to speak, by that of the pulmonary complication. Most generally the endocarditis follows a pneumonia, coming on the same day of, or many days after, the defervescence of the pulmonary inflammation; then the fever returns, the cardiac symptoms become more pronounced and along with these a typhoid state is established. Secondly, endocarditis may come on *pari passu* with cerebral symptoms, these being due to a grippal suppurative meningitis. Finally, in rare cases pneumococcic endocarditis may be developed primarily without any pulmonary complication.

It must not be considered, however, that an infectious endocarditis developed during the course or the convalescence of grippal pneumonia is always due to the same germ. Other micro-organisms than pneumococci have been observed. Streptococci and staphylococci have been found in the valvular vegetations. This proves, once for all, that we do not have one but many kinds of infectious endocarditis; it further shows that the grippe is the resort, so to speak, of numerous germs, and that the disease is characterized especially by the frequency of microbian associations and of secondary infectious processes. This explains why influenza is such a complex and troublesome affection. An important case is reported Jaccoud (*Acad. de Scien.*, May 24, 1886) which sustains this assertion. At the autopsy of the patient, there were found pneumococci in the hepatized lung and staphylococci in vegetations of the mitral valve; that is, there was an association of the parasite of pneumonia and of the microbes of suppurative processes.

c. Grippal Myocarditis.—This is one of the results of the infectious nature of the disease. Myocarditis may exist during an attack of influenza as during other maladies of the same nature. At the autopsy of a case the cardiac muscle exhibited a deadly pale coloration; the organ was heavy, of a soft consistency; and on carefully examining the coronary arteries there was found an obliterating endarteritis upon which depended the lesions of the myocardium.

A Russian physician, Wassilief, of Alexandre Hospital at St. Petersburg, has pointed out myocarditis as one of the complications of influenza. I have told you that it is associated with pericarditis, and, undoubtedly, with myocardiac degeneration to which were attributed the serious symptoms exhibited in the three cases reported by Letort. These symptoms were weakness of cardiac action—frequent, small, uneven, irregular and trembling pulse; painful sensations over the middle of the sternum; earthy pallor of the face; cold and cyanosed extremities; and rapid death. Acute myocarditis, however, is rarely so pronounced, and does not generally occur except through atony or cardiac collapse, or still when arhythmia, with or without tachycardia, is present. Arhythmia must always be carefully studied because it is a symptom that plays an important part in all acute or chronic myocarditis, since the rythmical action of the heart is a function of the cardiac muscle and not of the nervous mechanism of the organ. Sometimes also, the irregularity of the pulse may be manifest as a phenomenon alone of the grippal state, of which Potain has cited two examples; but this simple arhythmia, free from all other symptoms, is not sufficient by itself to constitute a diagnostic point of acute myocarditis. It is, in influenza, characterized by a weakness of the first, and afterwards the second sound; sometimes by leipothymia, syncope, embryocardia (of which I shall speak later on) and a species of a peculiar *trotting* sound. This is due to an effort of the systole to occur in two periods, and may be represented by a long period between two brief ones, while the true galloping bruit is characterized by two short periods followed by a long one, or a long one followed by two brief ones.

A *sudden* or simply *rapid* death may be observed during an attack of the grippe, following a syncope. To explain this phenomenon three hypotheses may be advanced: Is the accident the result of profound nervous alterations which we shall study later on, or the result of a myocarditis, or of a species of anginous syncope? When the first manifestation of the malady is one of syncope, and when it is accompanied (as I have seen it many times) with sudden weakness of the lower extremities, it can not be attributed either to a myocarditis, which cannot be developed so rapidly, or to a cause of anginous character.

It must be admitted that the affection, from the start, may localize itself in the medulla, which is proved by the observation of Burlureaux (*Gazette Hebdomadaire*, January 25, 1890) relative to a patient who, immediately after an attack of syncope, had epileptiform convulsions. A patient of Potain (quoted by Duflocq in the *Rev. de Méd.*, 1890) was suffering from intestinal grippe; in a short time the pulse rose to 130, after a while to 150; at times this was small, compressible and filiform; suddenly death occurred, brought on by an attack of syncope. May the action of intestinal reflexes be considered in this case? Such a thing is possible, but it is difficult of demonstration.

Another patient had an initial syncope, together with acute lumbar pains. It is probable that in this instance the nervous system was involved. Still another patient under my observation who after some time exhibited symptoms of arterio-sclerosis of the heart (dyspnœa and somewhat vague symptoms of anginous nature), was taken after an attack of influenza with a severe præcordial pain and died suddenly. It is difficult not to believe, in this case, in the existence of an anginous syncope.

Grippal angina pectoris has been likewise observed during the various epidemics of influenza. The epidemic of 1729 was especially characterized by syncope, by an intense and lancinating pain over the præcordial region. Recently, in 1856, Bertholle called attention to a sensation of constriction occurring over the sternum. A short time before, Malcrops, of Brussels, in a work upon "the grippe and its epidemics" (1884) had referred to a pain felt over the superior fourth, third or half of the sternum.

In 1889 I made some significant observations, and I then insisted upon two things especially: Firstly, that in anginous patients the sterno-cardiac attacks are of an aggravated character, these being intense and of frequent occurrence; secondly, (*Rev. gén. de Cli. et de Thér.*, January 16, 1890, and in this I was followed within three days only by Peter (*Bullet*) *Méd.*, January 19, 1890) that there exists a *grippal angina pectoris.*

Other authors have made similar observations, and thus an English physician, Mariet (*The Lancet*, March 29, 1890), has reported the case of a patient who succumbed to an anginous attack on the 18th day of the grippe. In the majority of cases, however, it may be said that in the patients suffering from chronic angina, the attacks of angina are suddenly aggravated by influenza. I hope, at my next lecture, [to appear in the next issue of the REPORTER], to show you the reason why all cardiac affections are thus aggravated, and shall consider the damage wrought by the grippal poison upon the nervous mechanism of the heart and the blood-vessels.—*Le Bulletin Médical*, February 3, 1892.

COMMUNICATIONS.

A SUCCESSFUL CASE OF LATERAL ANASTOMOSIS OF THE ILEUM FOR MALIGNANT STRICTURE, WITH A DISCUSSION OF THE OPERATIVE TECHNIQUE.*

BY WILLIAM EASTERLY ASHTON, M. D,
GYNÆCOLOGIST TO THE PHLADELPHIA HOSPITAL.

I saw the patient, Mrs. E. C., for the first time on November 28, 1891, in consultation with her physician, Dr. Thomas Curry, of this city. She gave the following history: Twenty-eight years of age, and married nine years. She had had five children at term and two miscarriages. Three years ago, when five months pregnant, she fell from the window of the second story of her house, striking with her back and occiput upon the pavement below. This accident resulted in a slight uterine hæmorrhage, but the pregnancy was not interrupted, and she went to full term. Shortly afterward however, she began to suffer from epileptic attacks. These continued up to eighteen months ago, since which time she has been entirely free from them. On August 20, 1891, she was delivered of a hydrocephalic child. The labor was natural, and was not followed by any puerperal complications. At this time she was in excellent health, and weighed 185 pounds. Shortly after getting up, however, her health began

*Read before the Philadelphia Medical Society, March 9, 1892.

to rapidly fail. She began to have frequent attacks of violent abdominal and pelvic pain, preceded by the movement of gas in the intestines. Her abdomen was always greatly distended, which added to her discomfort. There was obstinate constipation, and the bowel movements could only be induced by purgatives and rectal injections. These movements were always small in amount, and caused a great increase in the abdominal pain and tenderness. She had constant nausea and vomiting, and the abdominal distension was increased after taking food. She continued to lose weight and strength, and suffered from night-sweats. Seven weeks after her confinement her menstruation appeared, but it has not recurred since. Her weight at the time I first saw her had been reduced to 115 pounds.

On examination, I found the abdomen distended below the umbilicus. It had the appearance of a tumor, filling up the lower part of the abdominal cavity. The abdomen above the umbilicus, although distended, was not greatly so. Percussion gave a tympanitic note over the entire abdomen. No tumor could be felt on palpation. Indigation gave negative results. As I was unable to demonstrate by my examination the existence of a new growth, I looked upon the cause of the chronic obstruction as being due to intestinal adhesions, the results of a localized peritonitis. Cœliotomy was, therefore, urged, and consented to by the patient.

Operation. Cœliotomy was performed at the Polyclinic Hospital on November 30, 1891, Dr. J. H. Gibbon, senior resident of the hospital, and Mr. Louis J. Borsch assisting in the operation.

Upon opening the abdomen, which was done in the median line below the umbilicus, the omentum was found adherent to and blocking up the entrance to the pelvic cavity. After freeing these adhesions, the pelvis was examined, and its organs found in a normal condition. The small intestines were greatly distended and adherent to each other at several points. These were then carefully separated. Up to this stage of the operation the conditions found seemed to confirm the diagnosis of an old peritonitis, resulting in intestinal adhesion. The existence, however, of the distension indicated a stricture at some point in the bowel, due either to additional adhesions or a new growth. With this view of the case in mind, the examination was carried still further, and resulted in finding a large cancerous mass situated in the ileum and involving the mesenteric glands. At this point the stenosis of the gut was so marked that it was with difficulty the gas could be pushed through it. As the involvement was extensive, any attempt at resection would have dangerously prolonged the operation without giving the patient the slightest chance of permanent relief. It was therefore decided to perform a simple lateral anastomosis without resection. Ten inches of the ileum on each side of the stricture were stripped of their contents, and a ligature of soft rubber tubing passed through the mesentery, and tied around the gut at each end to prevent the regurgitation of the intestinal fluids. The field of operation was then protected by packing carefully with gauze pads. Two openings into the intestine were then made, one upon each side of the stricture, and both about three inches distant. The excluded portion of the gut was then thoroughly irrigated through these openings. In making the anastomotic communication I used the solid rubber rings, and, to add further to the security of the parts, "the right-angle continuous suture" was carried entirely around the anastomosis. No irrigation of the abdominal cavity was employed, and the abdomen was closed without drainage. The entire operation lasted twenty-five minutes, and the patient was placed in bed with a good pulse and normal temperature.

After-history. The patient made an uninterrupted recovery, and was discharged from the hospital in twenty-eight days. The temperature was normal throughout her convalescence, except on the day following operation, when it reached 100.4° F.; the pulse on the same day was 100 per minute—the highest number of beats during her stay at the hospital. A hypodermatic injection of morphine and atropine was given immediately after the operation, and repeated on the second and third day as the patient was somewhat restless. The patient for the first three days was nourished with nutrient enemas, and then food was given by the stomach. The bowels were freely moved on the fourth day, following the administration of calomel. There was no tendency to constipation at any time. The rings were passed on the eighteenth day. They were discharged whole, their segments not having become separated.

Immediately after operation the abdominal pain and distension entirely disappeared and remained absent throughout her stay at the hospital. The patient vomited only once, and then on the twelfth day following the administration of salts. At the time of her discharge she had gained decidedly in weight and strength, and was free from all her previous symptoms.

The patient was seen by Dr. Curry on the 24th of last February, three months after the operation. She had improved steadily in health; her bowels had moved naturally every day; there had been no vomiting, and the abdominal pain and distension had not returned. She had gained thirty-five pounds in weight since the operation, On the 10th of February her menses returned, after an absence of four months.

I shall pass at once to the discussion of some points of importance in the technique of lateral anastomosis.

The rings employed. Those used in this operation were made of solid rubber cording, and were devised by Dr. Baldy and myself, and employed by us in our experiments upon dogs. The advantages of these rings have been fully discussed in our paper upon "Experimental Studies in Intestinal Surgery,"* and I shall not refer to them here. Recently I have modified these approximation rings, doing away, I believe, with the only real objection that could be advanced against them, namely, that they allowed too small an opening between the intestines. As I now make them they are oval in shape instead of being round, as they were originally. This is accomplished by means of a strand of catgut fastened across the ring at each end. They have six ligatures attached in place of four; and the segments of which the ring is composed, as well as the threads, are held by means of catgut. With a ring of this kind an anastomotic opening may be made in the intestine, oval in shape, and having the following dimensions: 1¾ inches long, ½ of an inch wide at the centre, and ¼ of an inch at either end.

Additional sutures about the anastomosis. It is now generally held by operators that additional sutures about the seat of operation give greater security to the parts and lessen materially the dangers of leaking. For this purpose I employ the "right-angle continuous suture" of Cushing, using a simple knot for its beginning and ending, as advised by Keen, instead of the original complicated method. This suture may be introduced with great rapidity, and holds the serous surfaces together with accuracy. It is good practice to carry this suture completely around the anastomosis in order to be sure that there will be no leaking at any point.

Cleanliness during the operation. It is impossible to do an ideal aseptic operation where the intestines have been opened. If, however, the parts be kept carefully cleaned there will be practically but little danger of septic infection following. Those of us who do abdominal work must have frequently observed how quickly a blood-clot or other foreign material becomes adherent to the serous surfaces of the intestines, and with what comparative difficulty it is removed. No amount of subsequent irrigation will suffice to detach some of these adherent particles, and it is necessary to pick them off with the fingers. How easily, under these circumstances, a small particle of septic material may be overlooked and become the centre of an infection can be readily understood. To prevent the danger of this source of infection the seat of operation should be frequently douched during the operation with warm sterilized water. This I believe to be a most important point in the technique of these cases. It certainly can do no harm, and it not only keeps the parts clean, but it at the same time lessens the dangers of shock by keeping the intestines warm.

Rapidity in operating. In no field of surgery is time as important a factor for success as in abdominal operations. A surgeon may have the most profound knowledge of the subject, he may deal with all the accidents and complications which may arise with rare judgment and decision, and yet his results will be bad unless his operations are rapidly performed. Good results in abdominal surgery mean rapid work—that is, no shock, no ether-saturation. Park†, in discussing those sources of septic infection not concerned in the wound itself, throws out a most valuable hint bearing upon this subject. He says: "There is good reason to think that chloroform and ether administered for some time may produce such changes in the blood and tissues that vital processes of repair, cell-resistance and chemotaxis may be so far interfered with as to facilitate subsequent infection."

Feeding after operation. The tendency of most surgeons to delay giving food by the mouth, and their reliance upon rectal feeding are, I am convinced, mistakes in the early after-treatment of cases of anastomosis. If we employ in our operations rings which closely approximate the surfaces of the viscera and use additional sutures around the seat of anastomosis there can be no reason to doubt the security of the parts. It seems improbable, under these conditions, that the natural peristaltic action of the intestines

*Proceedings of the County Med. Soc. (Phila.), vol. xii., 1891.

† "Wound infection," etc., *American Journal of the Med. Sciences*, Nov., 1891.

would be sufficient to cause leakage. To throw light upon the question of early feeding after intestinal anastomosis I shall refer to the following cases of gastro-enterostomy. Brookhouse and Taylor ‡ report seven cases, with three recoveries and four deaths. In the cases which recovered, feeding by the mouth was begun on the second day. They considered early feeding as a most important factor in their successful cases. Page|| reported a series of thirty-six cases with fifteen deaths, which were in most instances due to exhaustion. Beaston* reports two cases of very great interest as bearing upon the necessity for early feeding by the mouth. The first case did well immediately after the operation, but died on the fourth day from asthenia; food and stimulants were not given by the mouth until a few hours before death. The second case was extremely weak and exhausted at the time of operation, but, nevertheless, made a good recovery. This patient was given thirty drops of brandy every hour by the mouth as soon as he came out of ether, and next morning feeding by the stomach was begun. In his remarks upon these cases he says: "Do not place too much reliance upon rectal feeding. Food in small quantities should be given early by the mouth, for in this way only can the tendency of death from asthenia be successfully combated." Jessett,† in speaking of the report of seven cases with two deaths, one of which was on the sixth day and the other on the seventh, both being due to exhaustion, says: "Both would have recovered if fed earlier."

There can be no doubt that exhaustion is the cause of death in a large number of these cases as well as in anastomotic operations in other portions of the intestinal tract, and it is impossible, with rectal feeding alone, to prevent the fatal issue. In those cases which are seen early by the surgeon and are not exhausted the question of early feeding by the mouth is not of first importance. On the other hand, however, cases which are weakened by their disease should be given food and stimulants by the stomach at the earliest possible moment after operation.

Closure of the anastomotic opening. One of the gravest questions in intestinal surgery is the danger of subsequent closure of the artificial communication. This question cannot be settled until we have examined the seat of operation in a large number of cases which have recovered from the operation, but who have died subsequently at various periods of time. Although, as yet, but little has been done in this direction, still there have been a few such examinations made which may be referred to with advantage. Larkin * reported the results of a post-mortem examination upon a patient of his own who died five months after he had performed a gastro-enterostomy for malignant disease. He found upon filling the stomach with water that it passed into the duodenum through the pylorus, but would not pass into the intestine through the artificial communication. After opening the stomach he failed to detect any trace of the anastomosis. He then opened that portion of the jejunum which had been attached to the stomach, and was able, with a fine probe, to pass into the latter. The malignant disease had not involved the seat of operation. Jessett † lost a case on the fifth day after performing a gastro-enterostomy, and found upon post-mortem examination that the artificial opening was quite patent and healthy, and that the bone plates were nearly digested. Sainsbury ‡ lost a case on the second day after performing a gastro-enterostomy. The examination of the stomach after death showed a closure of the opening. He says: "The opening into the jejunum was patent when probed by the finger; but that there was an impediment which must have been valve-like is proved by the distended stomach, and the fact that water injected into the stomach before dissection did not escape into the jejunum." In this case rings or plates were not used, the anastomosis being made by a double row of sutures. Beaston || reports two cases upon whom he made post-mortem examinations following gastro-enterostomy. One of these patients died on the fourth day following operation. He found the bone plates "greatly acted on by the digestive fluids, being reduced to the thickness of the thumb-nail and broken up into small pieces both in the stomach and bowel. The knots of the uppermost lateral threads were plainly visible owing to the serous surfaces having fallen apart, probably on losing the support of the bone plates." The artificial opening he found would admit the forefinger. The second case died in four weeks after section from acute lung trouble. The artificial opening was found to be oval in shape, with smooth and

|| *London Lancet*, 1890, vol. ii, pp. 761–764.

regular borders, and barely admitting the index finger. Keen§, in referring to a case operated upon by Dr. Abbe; in which a lateral anastomosis was made, says: "The opening was large and seemed ample. The patient died some months later, and it was found that the opening had narrowed and contracted so that ultimately there would have been complete obstruction."

In all of the cases just mentioned the incisions into the intestine and stomach were ample, measuring from one inch to one inch and a half in length. With the exception of Dr. Abbe's case the bone plates were used in all of them.

There are several factors concerned in causing a narrowing of the artificial communication following lateral anastomosis. First, the natural tendency of the tissues themselves to retract; second, the contraction of the cicatrix following the healing of the incision; third, the direct union of a part of the incision due to the immediate contact of its edges; and fourth, the opening into the bowel not being sufficiently large or of a proper shape.

The first of these causes cannot be avoided, as contractility and retractility are inherent properties of these structures. To prevent the contraction of the cicatricial tissue, Jessett* and Clarke† advise sewing together by a continuous suture, either of silk or catgut, the cut edges of the serous and mucous coats of the incised viscera. This brings the raw surfaces together, and is followed by direct union—an important fact, as it does away, to a great extent, with the formation of a cicatrix. This method of dealing with the edges of the incision will also prevent the danger of union from direct contact. Direct union of the cut edges of the bowel as a cause of closure of the opening has, I believe, been overlooked by surgeons. Its importance, however, can hardly be questioned. For instance, the case of Larkins, quoted in this paper, goes a long way toward the support of this theory. For how else could we explain the fact that five months after section the opening only admitted a fine probe, unless we admit that in the beginning the edges became in part united. Again, Mr. Larkins performed a jejunostomy upon this very patient nine weeks after the gastro-enterostomy, on account of symptoms of closure of the artificial opening, and she was then kept alive by feeding directly into the jejunum. It is hardly likely that a large incision in the nine weeks could become closed by the retraction of tissues and the contraction of the cicatrix alone. Furthermore, Beaston's two cases both point in the same direction—one dying the fourth day, and the opening only admitting the fore-finger, while the other barely admitted the index finger at the end of one month. In all of these cases long incisions were made, and their rapid narrowing certainly teaches us a lesson. I do not for one moment wish to be understood as stating that direct union of the edges is the only factor in the case, but I do wish to emphasize its importance as a cause. Dr. Keen* has made a suggestion of great practical value in the technique of lateral anastomosis. He advises, instead of making a simple slit, to pinch up the bowel and remove an oval piece. This plan, he believes, would lessen the danger of contraction taking place. While I do not believe that this suggestion would in any way lessen the amount of contraction, I do believe that it would, by lessening the danger of direct union of the cut edges, prevent to a great extent the tendency to closure. Another point of importance is, as suggested by Jessett, to pass the lateral sutures of the ring as close to the edges of the opening as it is consistent with safety. In this way the edges of the incision are kept wide apart. The length of the incision for an anastomosis should be from one and a half to one and three-quarters of an inch. An opening of this size, made oval in shape and having its mucous and serous edges united by a continuous suture, offers, I believe, the best chance of remaining permanently patent.

My experience has been that it is extremely difficult to cut out an oval piece of gut with scissors, as the opening is apt to be irregular or larger than we desire. I saw a well-known operator make this mistake, and he was obliged to narrow the opening by stitching it across with catgut. To overcome this difficulty I have devised a steel punch for the purpose. With this instrument we are able to make the opening of a definite size and its borders clean and sharp—factors of great importance. The incision is oval in shape, one and three-quarters of an inch long, one-half inch at its centre, and one-quarter of an inch across at each end. By having the ends of the opening abrupt instead of tapering, there is less danger of direct union.

§ Proceedings Phila. County Med. Soc., 1891, vol. xii, p. 93.

Brit. Med. Jour., Lond. 1891, vol. i, p. 1377.

†*Brit. Med. Jour.*, Lond, 1891, vol. i, p. 798.

*Proceedings Phila. County Med. Soc., 1891, vol. xii, p. 93.

In conclusion, I desire to call attention to the following points:

1. The necessity of frequently douching the seat of operation with warm sterilized water to prevent the dangers of infection and shock.

2. That rapidity in operating is of great importance for success.

3. That early feeding by the mouth should be employed in all cases, especially in those which are weak and exhausted.

4. That early feeding by the stomach does not add to the dangers of leaking, as the parts are perfectly secure if proper rings and additional sutures are employed.

5. That an important factor in causing subsequent closure of the anastomotic opening is a direct union between the edges of the incision.

6. That the danger of subsequent closure of the artificial communication is materially lessened by using a steel punch in making the opening, by stitching the edges of the serous and mucous coats of the bowel together, by placing the lateral sutures of the ring as close as possible to the margins of the incision, and lastly by making the anastomotic opening sufficient long and of an oval shape.—(*For discussion, see Society Reports.*)

SCROTAL HERNIA REDUCED AFTER THREE WEEKS' MANIPULATIONS.*

By A. B. HIRSH, M. D.

To illustrate the value of massage in this condition I here report the brief notes of a case recently occurring in practice:

A. L., aged forty-seven years, of medium height and sparely built, is predisposed to hernia because of his laborious calling, being a boiler-maker. In 1872, after lifting some weighty object, the gut descended through the right inguinal canal, appearing at the external ring. A proper support was immediately applied. As, however, no pain or inconvenience was felt, he gradually omitted wearing his trusses (of which a variety was used), so that the tumor finally became scrotal; although always reducible. Six years ago he first noticed that he could no longer return the mass, and he therefore left off the truss altogether; but at no time previous to last fall did it give him any concern, as the bowels always acted normally, and he was able to follow his trade without interruption.

Although for some years in attendance on the family, it was not until November last that I first learned of the existence of the hernia, and then he was already laboring under symptoms of obstruction. Prolonged efforts at reduction were of no avail, so that I advised radical measures. The scrotal mass evidently contained omentum as well as gut. He had been for three days without movement from the bowels, although active purgatives had been repeatedly taken, and fecal vomiting had begun some houre before my arrival. To the operation of herniotomy he objected decidedly, insisting on palliative measures alone, so that I was bound, with misgivings to accede. High irrigation by the rectal tube was done, carminatives given, the intestinal tract acted on by active salines and cholagogues, with relief to the fecal vomiting and more urgent symptoms. This purging was followed up daily for nearly a week, ice-bags constantly applied over the tumor, the foot of the bedstead elevated, and a diminished semi-solid diet allowed. Then the services of a masseur were called into requisition, seeking to loosen up any scrotal attachments of the mass, while I saw the patient only at occasional intervals to direct the cause of pressure by the manipulator, and by three weeks' longer efforts the entire mass was returned into the abdominal cavity for the first time in six years.* Every troublesome symptom had disappeared, and, by wearing his ordinary retentive truss he was again able to follow his ordinary occupation.

I wish, in conclusion, to briefly emphasize the facts that in some cases of hernia of long standing, unreduced, it may be presumed that adhesions had formed within the scrotum.

In such instances, where operation is declined, or the condition of the patient prevents it (provided a diagnosis of acute strangulation can be excluded), continued taxis may relax the parts or lengthen or break the adhesions, and allow of a reduction of the abdominal contacts.—(*For discussion, see Society Reports.*)

ARISTOL IN SCROFULOUS RHINITIS OF CHILDREN.

This drug (*Lo Sperimentale*, No. 23, 1891) is recommended as giving excellent results, if insufflated into the nose, in the scrofulous rhinitis of children. It is also of value in chronic eczema when given according to the following formula:

℞ Aristol.....grammes 10.
Lanoline (or) vaseline..... " 50.

*Read before the Philadedphia County Medical Society, March 9, 1892.

*I should state that each daily séance lasted about half an hour.

A SCIENTIFIC CURE FOR HERNIA.*

By BENJAMIN T. SHIMWELL, M. D.,
LECTURER ON SURGERY IN THE MEDICO-CHIRURGICAL COLLEGE.

All methods devised for the radical cure of hernia seek to reach their object by obliteration of the canal, and by this plan to retain the protruding gut. This is the treatment of effect, not of cause.

While fully recognizing the comparative frequency of this trouble, we must not overlook the fact that it is in the minority. As we are all subject to the same exciting causes we should look for some anatomical reason that will explain its occurrence and non-occurence, and why after operation, where fibrous tissue in apparent quantity existed, return was possible. There must be more than the production, or rather reproduction, of a canal from the abdomen to the scrotum to account for it.

The first thing, then, to consider is not the inguinal rings or canal, but the intestines, the prime factor in the case.

The intestines are not a tube lying perfectly free in the abdominal cavity, to be pushed here or there, making pressure at this or that point. If they were attached but to the pyloric end of the stomach and to the anus, then it could readily be seen how intra-abdominal pressure could possibly rupture any weakened point in the belly wall, with consequent protrusion of the gut. Instead of being so arranged their position and action are limited by the folding around them of the peritoneum forming the mesentery.

Careful examination of the body in the dead-room fixes a normal relative position for this limiting membrane. Its point of attachment to the parietes begins to the left of the second lumbar vertebra. Its insertion then follows a line obliquely downward and to the right, to attach itself on the right iliac fossa. Its average length is eight inches; an increase above this is an abnormal state, and on this increase in length depends the production of hernia. The examination of numbers of bodies has proved beyond cavil that when a normal condition of the mesentery exists, it is impossible to drag the gut into the inguinal or femoral rings.

Is it scientific to say it is chance that prevents the whole human race from having hernia? Also to lay it to the firmness of attachments of the opposing surfaces of the inguinal canal, or the structures that cover a present hernia? The pushing forward of the superimposing layers of the tissue and separation of the obliterated canal speak ill for its preventive power. If they are preventive, then the sudden rupture would give us more serious consequences in primary protrusion than experience shows. The canal does not show the after-conditions that follow usually from tearing, which would be excessively marked here if strong union had taken place. Neither subjective or objective symptoms are present. It is coaptation, not union with firm tissue formation.

It is clear to my mind that the normal length of the mesentery is the preventive factor in the non-production of hernia. If not so, then no one would escape. The exigencies of life and our surrounding conditions are such that all of us at times are subjected to violent strains, giving rise to intra-abdominal pressure sufficient to rupture the internal openings, and to allow the gut to enter the canal.

If these assertions are true, then any operation which has been suggested does not prevent, but modifies. Therefore, any procedure seeking to prevent hernia by obliteration of the sac does not cure. The possibility of return exists.

What is the rational treatment? The opening of the abdomen and shortening of the mesentery. The width of the mesentery does not increase in adult life, but the length is liable to.

The opening of the abdomen and shortening of the mesentery may be objected to on the ground of possible risks. The safety of the operation of abdominal section is settled. The shortening of the mesentery offers no objections. It may be said that the blood-supply of the intestines may be interfered with. Careful experiments show the reverse.

Further, to prove that peritoneal inflammatory changes do not affect the blood-supply is instanced in the omentum after diffuse peritonitis. Operations during the acute stage and post-mortems have shown me conclusively the possibility of contraction occurring without strangulation. In every case of acute peritonitis, unless adhesions have taken place, or, in fact, any case where the omentum has been much handled, we always find it drawn up to its gastro-duodenal attachment as a knotted mass. Still its vitality is maintained. Also the invaginated mesentery into the divided bowel, in the operation of intestinal anastomosis, does not lose its vitality by contraction and imflammation. Here there is not only change by contraction

*Read before the Philadelphia County Medical Society, March 9, 1892.

due to the invagination, but also thickening from the inflammatory products thrown in and about its attachment. That this portion of the mesentery still supplies the bowel with blood is proven by the number of experiments I made, to show the division of the mesentery at the point of invagination caused gangrene. This proves that though changed in its structure pathologically, it does not interfere with its nutritive function as a carrier of blood.

It is understood that the value of an operation lies as much in its freedom from risks as in its ability to maintain its advantages when successful. The freedom from risk has been one of the so-called advantages claimed for the radical cure suggested. Can this be truly said of these methods? It is not always in the province of any operator to say when the operation is finished that he has not divided the spermatic duct. This is not recognized in unilateral operations, providing the other organ and duct is viable, but if not, or if in any subsequent time inflammatory changes take place, it is plainly seen the disadvantages that would arise. There is also the possible atrophy of the testicle from injury to its nerve-supply. Then, again, sharp attacks of peritonitis have occurred with consequent changes. There is law of serous cavities that is definite: "Any inflammation, unless limited by adhesive contact, is diffused over the whole surface." This will hold good here as in an operation done through section.

The largest part of the mesentery is usually confined to about five feet of the bowel included in a space beginning at a point six feet from from the duodenum. If this is above the average length it is apt to hang into the pelvis, and is, in all probability, the portion protruded. It is but reasonable to suppose it is the same loop that is recurrent in its extrusion. There would be no difficulty in locating this portion, as the hernia would be present.

The shortening is done by folding the mesentery over on itself, and holding in this position by interrupted sutures. The intestine can be delivered, folded, sutured, and then replaced, and successive portions so operated upon. This is a step that of necessity requires experience in handling the intestine that is only got by practice. The delicacy of the mesenteric tissue is understood. The union of the attached surfaces is rapid, and having been so shortened, there is no possible relengthening. Experiments, operations, and post-mortems in cases which had peritonitis show persistent shortening of the mesentery, the intestines being drawn nearer the spine.

The operation can be done perfectly aseptic, obviating risks. The bowel is not injured. It is done quickly, closure is made, and the patient out of bed in a few days.—(*For discussion, see Society Reports.*)

A BONE IN THE THROAT: TWO CASES.

By PROF. T. S. WIGHT, M.D.,
BROOKLYN, N. Y.

I wish to make a note of two cases which recently came under my observation: one, of a patient who said she swallowed a bone; and one in which a bone was found in the throat. I am induced to report these cases because the subject is always important, and because the treatment in one differed from that in the other.

Case I. A middle-aged woman of hysterical temperament thought she had swallowed a bone; and felt it in her throat, as she pointed out, near the top of the sternum. Her family physician could not make her believe that the bone was not in her throat, and so she continued to feel it for several days. I saw her, and after the doctor gave me the clinical history, and when I made an examination, I told her that she was mistaken as to the bone being in her throat; and I told her that as the bone went down it scratched her throat, and that she still felt the scratch. After I passed a tube through the œsophagus into the stomach she felt much better, and came to the conclusion that the bone had gone into the stomach. In a few days she entirely recovered from her depressed and anxious state, and was soon as well as ever.

Case II. Recently a very stout gentleman came into my office saying he had a bone in his throat. He had every appearance of being a true sufferer: he had difficulty of breathing and was expectorating somewhat profusely. On inspection I could not see anything in his throat. Then I wound a bandage around my left forefinger, leaving the end of it exposed, and passed it into his throat as far as I could; I thought I could feel a small bone on the left side down as far as my finger reached. The object of the bandage was the protection of the finger against the action of the patient's teeth. Then I passed down a pair of angular throat forceps, and closed them upon what seemed to be the foreign body. The mucous membrane got slightly nipped, and as I withdrew the instrument its jaws tightly held the piece

of bone, which was exactly seven-eighths of an inch in length and about one-twentieth of an inch in diameter. The relief was immediate.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting, March 9th, 1892.

Dr. Noble read a paper on "A Year's Work in Minor Surgical Gynæcology at the Kensington Hospital for Women," (see next issue of REPORTER.)

This was followed by an article by Dr. Ashton on "A Successful case of Lateral Anastomosis of the Ileum for Malignant Stricture, with a discussion of the Operative Technique." (see p. 565.)

DISCUSSION.

DR. J. M. BARTON: I agree with what Dr. Ashton has said in almost every particular. There are one or two points, however, to to which I would like to call attention.

The Doctor has spoken of the importance of keeping the abdomen open for the shortest possible time during an operation. I fully agree with him in this, and in my own abdominal operations I often sacrifice something to secure brevity of operation.

To make the operation as short as possible it would be very convenient for us to know, before opening the abdomen, exactly what we have to do. With our present knowledge this is impossible, but the history, even now, will often throw some light on the nature and seat of the obstruction.

Under all circumstances, the history in each reported case ought to be carefully recorded, not omitting apparently unimportant details, so that in the future, in similar cases, the diagnosis may be fairly accurate before surgical interference.

The vomiting in this case, unaccompanied by any tenesmus, was rather unusual. Where the obstruction is so low, tenesmus is more apt to be a permanent symptom than vomiting. The rapid emaciation would point to malignant disease. The sweating also would be suggestive of a far advanced maglignant growth or encysted pus.

I fully agree that the feeding should be begun early. In my stomach cases, where the danger of giving food early is greater than in intestinal injuries, I have found that where I was compelleed by the condition of the patient to give food at once, it was well borne. Examining the literature of the subject, I found that the cases that were fed early did not seem to suffer thereby. Where the operation is some distance from the stomach, there is no reason why food that should be absorbed by the stomach should not be used at once.

The Doctor has suggested that the narrowing of the opening may possibly be due to immediate union. In the history of the cases that were examined a few days after operation it does not appear that the opening was materially contracted, while in those examined some months after operation it was found firmly contracted. Where the operation it performed for non-malignant disease, and the patient is expected to live for some time, this contraction of the opening is of the utmost importance. I doubt whether the removal of an oval piece will prevent it. I am not prepared to make any suggestions, but this is one of the difficulties which I fear we shall find trouble in overcoming.

DR. B. T. SHIMWELL: Reference has been made to the use of sutures around the point of anastomosis. I have had considerable experience experimentally with operations on the bowels, and I find that the moment you interfere with the bowel paralysis occurs. In the paralyzed portion of the bowel no gas or fecal matter will enter. I therefore cannot see the necessity for sutures. When perfect coaptation with the ring is made one or two additional sutures is all that is needed, and I cannot understand why we should spend time in putting in these extra sutures, for it requires some time for the bowel to regain its normal tone. If the sutures are well applied and are well tied you have close coaptation, and adhesion is so rapid that there is firm union by the time the tone of the bowel is regained.

DR. JOSEPH HOFFMAN: I have often heard those gentlemen who do anastomosis talk about paralysis of the bowel as a necessary sequela to interference with the intestine. In ordinary abdominal surgery, where adhesions of the bowels are often extensive, we do not get paralysis even when we had to stitch down to the mucous coat. I have seen cases where it was necessary to stitch six or eight inches of the bowel down to the mucous coat, and the patient has recovered without paralysis of the bowel. I should like to know what the interference is which is supposed to cause paralysis of the bowel.

DR. J. PRICE: This matter of paralysis is an interesting one, and I am inclined to

ask the same question that Dr. Hoffman asked. Paresis of the bowel requires something more than local interference. If simple anastomosis with a few sutures is responsible for the paresis it is surprising that we do not have this condition in those extensive lesions of the bowel which we often have to deal with in suppurative and extensive disease. We often have to separate many inches of the bowel, and often have to stitch up lesions, but we do not see the least paresis. There is no perceptible distension. I am therefore surprised to hear gentlemen speak of paresis of the bowel following a few fortifying stitches in resection or in anastomotic work. It never occurred in my work, and I no longer look for it if the cases have been carefully prepared.

There is just one point in connection with anastomosis—not that I wish to criticise enthusiastic investigators or experimenters, but I desire to call attention to one very important point in intestinal surgery. If you can possibly get along without resection or anastomosis, always do so. You will find that men like Martin, Lawson Tait, Bantock, and Thornton make a resection or an anastomosis only exceptionally. Some years ago I did more resection and anastomosis than I do at present. I constantly finish an operation with the bowel with a lumen not larger than a crayon. I do not hesitate to reduce the bowel in its normal axis. I have never had any obstruction follow anastomosis. The results have been most satisfactory, and some of the cases are of three or four years' standing. I might allude to one case: Last summer I operated upon a woman who was said to have rheumatism of the ovary. Her pelvis was simply full. It contained all the pus and viscera that you could get into it. One of the abscesses had perforated, causing a mesentery abscess, which had perforated the bowel at two points, the two openings being about four inches apart. The portion of the bowel between the openings was quite gangrenous. There I was driven to resection and took out six inches of bowel and V-shaped a portion of mesentery. I found that the mesentery was too thick for inversion, and I therefore stitched the bowel carefully, and six inches above the resection made a lateral anastomosis cutting out diamond-shaped pieces of the bowel. This woman never had a bad symptom. She passed flatus in twenty-four hours. There was enormous distension at the band of the resection. She made a perfect recovery, and is now doing her domestic work.

Dr. M. Price: I think the operation of anastomosis can be materially shortened by using Mrs. Supplee's sewing-machine needle, which I have suggested for passing the sutures. In this way the six sutures can be passed in a minute and a half. It obviates the entanglement of the sutures, which are apt to occur when the needles are threaded before the operation, and does away with the time used in threading them during the operation.

I congratulate Dr. Ashton on the recovery of the patient. I think that these are the most serious operations that we are called upon to do. In most cases the disease has already gone so far that resection is out of the question. By this operation he has unquestionably lengthened that woman's days and probably made her death much more comfortable. Some years ago I resected some six inches of the colon for epithelioma. The woman is still perfectly comfortable, and I have no doubt that her life has been prolonged several years. There is no doubt that if the operation is done by a man familiar with the work, 95 per cent. of recoveries can be counted on. Suture of the intestine is one of the safest procedures in surgery.

I think that Dr. Shimwell is probably wrong in regard to paresis. I think we are justified in using every precaution, and the introduction of the ring should be supplemented by a whipped suture and reinforced over all by a Lembert suture. I have no hesitation whatever in saying that the operation is justifiable in cancer and is the only one left for us to do.

Dr. Ashton: While an early exact diagnosis is of importance, yet it is impossible in the large proportion of cases to make it. Even if we do not make an exact diagnosis, the opening of the abdomen causes very little harm if done as an exploratory incision.

In regard to the closure of the opening, I would say that some of these cases were examined as early as three or four days after operation. I cannot understand how an incision which is one and a half inches in length should in three or four days become so small that it would admit only the index finger, unless there had been primary contact and union.

I cannot agree with Dr. Shimwell in reference to intestinal paresis. I have never seen the condition follow even extensive injuries of the intestines. There is more shock to the bowel in severe injuries to the intestines in some pelvic case than in anastomosis. I agree with Dr. Joseph Price that we should not make an anastomosis if we can possibly

avoid it. I never hesitate to narrow the calibre of the bowel provided I do it in the direction of its long axis.

Dr. Shimwell then read a paper entitled, "A Scientific Cure for Hernia." (see p——.)

Dr. Joseph Hoffman: Dr. Shimwell's suggestion can certainly claim the merit of being new, but any procedure which strives to cure hernia by it must fail. If the portion of bowel that presented was always the same, the procedure might be logical. It is however, founded upon a false conception of the condition present. These conditions probably do not obtain in the greatest number of cases, and consequently the methods cannot be really a cure for the condition. Other things besides the bowels may constitute the hernia. In woman, the ovary may be present. The appendix may get into ring, and shortening of the mesentery will hardly cure that. Further than this, the omentum may constitute hernia. This is a prolific cause of hernia. It is probably at the bottom of most hernias primarily, and in many cases it precedes the bowel. We often find nothing in the ring. Strangulation has occurred and the gut slipped back, and the strangulation is back of the ring.

So far as considering shortening of the mesentery as a cure for hernia, we must understand what we mean by cure. Those who have done the most radical operations for hernia are not bold enough to say that they have cured a case—that is to say, so cured it that it will not come back. It cannot be held that such an operation will cure the predisposition for lengthening of the mesentery. So far as shortening of this tissue by inflammation is concerned, that is entirely theoretical. We cannot say that because the mesentery is thickened, it is shortened. The suggestion, while it has apparently a foundation in fact, must be taken entirely as experimental, and experimental in the line that it is not likely to be followed by practical results.

Dr. George E. Shoemaker: It is easy to decry anything which is unusual, yet every method must stand on its own merits. No consideration of this subject is complete which ignores the congenital defects of the ring, since these are at the bottom of many hernias. We find congenital hernia in the very young. Later in life the rings may be too large and weak from congenital defect, although no hernia is present, but a strain is suddenly thrown upon the parts and a hernia is produced. Such a shortening of the mesentery as would draw the intestine away from the abdominal wall is inconceivable under the physical laws which control intra-abdominal pressure; and with the intestine in contact with a weakened point protrusion is always possible.

Dr. T. S. K. Morton: Several years ago, a London surgeon—I think Mr. Morris—wrote quite an elaborate thesis on the subject of the mesentery and its relation to hernia. He apparently demonstrated that in the cases of hernia which he had examined there was distinct lengthening of the mesentery, which seemed to be peculiar to such cases. He found this in the very young, and he urged that the lengthening of the mesentery had a great deal to do with the occurrence of the hernia. I have seen this statement incorporated in one or two textbooks, and it seems remarkable that no one has before this thought of suggesting the operation of doubling the mesentery on itself to prevent the occurrence of hernia. I understand that Dr. Shimwell has done this operation upon animals with satisfactory results.

In this connection the recent suggestion of Mr. Tait in regard to treatment of hernia by abdominal section comes up with special force. If, as Mr. Tait tells us, it is exceedingly easy to draw the hernia back even when tightly strangulated, and if, at the same time we can shorten the mesentery and cure the hernia, and also deal with any prolapsed omentum, it would be a distinct advance in surgery. The method is not applicable to all cases of hernia. If the operation has any field it is in inguinal, and especially in femoral hernia. Dr. Shimwell has thrown out a very valuable suggestion, and I should hesitate very much to condemn the method until I had heard more about it.

Dr. Shimwell: I did not attempt to apply this method to all hernias. I think that any case in which the hernia can be maintained by a truss should not be operated upon. The method was suggested for those cases in which a radical cure was indicated. The method, of course, is applicable only to intestinal hernia. When we find omentum in the sac we do not hesitate to remove it. In peritonitis the omentum is contracted, and is found high up in the peritoneal cavity, and is of no use. The occurrence of congenital hernia is no objection to the method. The difficulty may not be originally in the canal, but the lengthened mesentery may permit the bowel to so press upon the canal as to weaken it. It seems folly to tinker with the canal and not try to remove the cause.

Dr. A. Hirsh read a paper on "The Reduction of Scrotal Hernia After Three Weeks Manifestations." (See page 570.)

Dr. Charles P. Noble: Last year I saw, in consultation with Dr. VanBuskirk, a woman who had fecal vomiting. She had a femoral hernia which had been strangulated for four days; she also had chronic bronchitis, and had a large goitre. Efforts at taxis had been made repeatedly without success. Operation was advised, but in view of the duration of the strangulation and the presence of bronchitis and goitre, the prognosis was unfavorable, and the family declined operation. The hernia remained down some days longer and then went up of itself, and the bowels moved, and apparently the woman was going to get well, but the prolonged obstruction had produced so much asthenia that she died of pneumonia. An interesting point is the length of time the bowel was down and then returned spontaneously.

Dr. M. Price: I admire Dr. Hirsh's confidence and energy, but I do not admire the treatment. The other night I was called to Trenton, N. J., to operate on a gentleman who had been treated for four days by a homœopath for stomach trouble, and was vomiting feces. Another physician being called found an inguinal hernia and telegraphed for me; I immediately etherized the patient and cut down upon the hernia, which was not even discolored. It was down in the scrotum; it had been there for months. It was not strangulated, although tightly held at the inguinal ring. A mass of hardened feces in the bowel was the cause of obstruction; there were no adhesions anywhere. I am confident that Dr. Hirsh had an obstructed but not a strangulated bowel. Most cases of strangulated hernia end in death no matter what procedure is adopted; I have never seen a case where four or five inches of the bowel were gangrenous, recover. Obstructed or incarcerated bowel is really the condition which is reported hernia.

The idea that a hernia can be easily reduced through the median incision is a mistaken one. I operate in the median line for doubtful femoral and inguinal hernia—that is, where there is a little tumor in these situations without evidences of incarceration. In such cases I have never been able to reduce the hernia from the inside; I have had to cut down over the tumor. In doing that, you have an excellent chance for making a radical cure. I have operated on a number of cases in this way, and there has been no return of the hernia.

Dr. Joseph Hoffman: Some years ago I had a case of inguinal umbilical hernia in an old lady, who had been seen by probably a dozen men; I was called in, and I massaged that hernia for four days, and I thought I had cured it. In two or three days I was called, and found that the patient was vomiting fecal matter; the trouble was that the hernia had returned *en masse*. This case shows the danger of attempting to cure strangulated hernia by manipulation. We may reduce the hernia without relieving the obstruction. Where the hernia has lasted for any length of time it is not safe to try to reduce it. Some two months ago I had a case where. if I had attempted to withdraw the hernia, I should have drawn back first a strangulated bowel nearly gangrenous with two inches of gangrenous omentum and two or three ounces of gangrenous fluid.

Dr. Hirsh: I should not advocate massage as a universal remedy in recent or old hernia. In this case it was applied because the family refused more radical procedures. The hernia having remained in the scrotum for six years, it is certainly fair to assume adhesions had formed, and the fact that three weeks were required in separating the strictures and in returning the mass makes one believe that there must have been adhesions to stretch. I was very careful to mention that it was an obstructed bowel, and not that actual strangulation had taken place.

TENDON GRAFTS INTRODUCED BETWEEN THE WIDELY SEPARATED ENDS OF DIVIDED TENDONS.

Dr. Rochet (*Gaz. hebdom. de méd. et de chir.*, June 20, 1891) obtained a very happy result in a case in which the ends of divided tendons of the superficial and deep flexors of the index fingers could not by any means be brought within two centimetres of each other. The proximal and distal ends were exposed in the usual manner. An incision was then made on the palmar surface of the finger at the joint of the phalanges, where the tendon of the profundus passes between the two lips of the tendon of the sublimis, and the tendon of the profundus was divided at this point. The portion of the tendon thus cut off was drawn out of its sheath, its upper end sutured to the proximal portions of the tendons of the sublimis and profundus, its lower end to the distal portion of the tendon of the sublimis. The proximal end of the small portion of deep flexor tendon which remained between the point where it pierces the sublimis and its insertion was then sutured to the lateral lips of the sublimis tendon. The patient recovered with good use of the finger.—*N. Y. Med. Jour.*

Caffeine,
Benzoate of soda.....āā ʒ i.
Strychnine.....gr. 1-5.
Camphorated water.....ʒ vi.
S. Tablespoonful three times a day.

POST-PARTUM ECLAMPSIA.

Dr. Strisover (*Mediz. Oboz.; Le Bulletin médical*, No. 5, 1892) advises subcutanous injections of the hydrochlorate of pilocarpine in post-partum eclampsia. He has treated ten cases thus, without a single death. He employs the following solution:

℞
Pilocarpine muriate.....cgms. 5.
Water.....gms. 4.
Inject a Pravaz syringeful at once.

He concludes as follows:

1. The hydrochlorate of pilocarpine is a certain remedy in eclampsia.

2. Cardiac weakness is no contra-indication to repetition of the injection when the spasms reappear.

3. Abnormal contraction of the pupil indicates that the disease is still at hand and that spasms are imminent.

COD LIVER OIL EMULSION.

℞
Cod liver oil.....fl. oz. 8.
Yolks of two eggs,
Tragacanth in powder.....grains 16.
Tincture of benzoin.....fl. dram 1.
Spirit of chloroform.....fl. drams 4.
Essential oil bitter almond.....minims 8.
Water to make.....fl. oz. 16.

Rub the tragacanth with a small quantity of the oil, then add the egg, and with constant trituration water and oil alternately and the flavoring ingredients until the emulsion is completed. About two fluid ounces of water will be needed.—*Br. and Colonial Druggist.*

REFRIGERANT LANOLINE OINTMENTS.

Unna has found that if lanoline fat and water be mixed in certain proportions the water easily evaporates, thus producing a cooling application:

1. Ointment to be used as a cold cream:

℞
Anhydrous lanoline.....parts 10.
Benzoated lard..... " 20.
Rose water..... " 30.

2. Imitation of Goulard's cerate:

℞
Anhydrous lanoline.....parts 10.
Benzoated lard..... " 20.
Solution subac. of lead..... " 30.

3. Salve for burns:

℞
Anhydrous lanoline.....parts 10.
Benzoate lard..... " 20.
Lime water..... " 30.

4. Refrigerant zinc ointment:

℞
Anhydrous lanoline.....parts 10.
Benzolated zinc ointment. ..... " 20.
Rose water..... " 30.

—*American Practitioner and News.*

HEADACHE POWDERS.

No. 1.

℞
Acetanilid.....drams 7.
Caffeine.....dram 1.
Sodium bicarbonate.....drams 2.

No. 2.

℞
Phenacetin.....grains 10.
Caffeine.....grain 1.
One dose.

No. 3.

℞
Acetanilid.....grains 3.
Caffeine.....grain 1.
Sodium bromide.....grains 7.
One dose.

No. 4.

℞
Acetanilid.....part 1.
Phenacetin.....parts 2.
Antipyrin..... " 4.
Dose 8-16 grains.

This combination has been found serviceable in specially obstinate cases of neuralgic headache.

Headache Capsules:

℞
Antipyrin.....grains 540.
Caffeine..... " 90.
Extract cannabis indica..... " 16.
Hyoscine hydrobromide..... grain 1.
Make into 30 capsules and give one every 1 to 3 to 5 hours.

Headache Mixture:

℞
Caffeine.....grains 20.
Ammonium carbonate. ..... " 20.
Elixir guarana.....ounce 1.
One dram every hour until relieved. For neuralgic headaches.

—*Western Druggist.*

LINSEED OIL EMULSION.

℞
Linseed oil.....fl. ounces 15.
Oil wintergreen.....fl. drams 2.
Oil cinnamon.....fl. " 2.
Powd. acacia.....ounces 10.
Water.....fl ounces 24.
Glycerin.....fl. " 5.
Simple syrup.....fl. " 10.
Dilute hydrocyanic acid.....fl. drams 2½.

PRURITUS ANI.

Dr. Josenh M. Matthews has obtained excellent results from:

℞
Benz. oxide zinc oint.,
Campho phenique.....āā ʒ ss.
M. Apply as often as necessary.

The campho-phénique may likewise be used pure, without detriment to skin or mucous membrane.—*Medical Bull.*, Feb., 1892.

FOR BALDNESS.

One of the best combinations in the treatment of baldness consists of:

℞
Pilocarpinæ hydrochlorat.....gr. v.
Otto de rosæ.....ℳ viij.
Olei r smarini.....f ʒ iv.
Liniment. cantharid..... .....f ʒ iv.
Glycerini pur.....f ʒ j.
Olei amydal. dulcis.....f ʒ ij.
Spts. camphoræ.....f ʒ iij.
M. S. To be rubbed well into the scalp, night and morning.

—*Whitla.*

COMPOUND ELIXIR OF CHLOROFORM.

The following formula (*The Prescription*, No. 1, 1892) is spoken highly of in cholera morbus and kindred complaints:

℞
Ol. cinnamon.....gtts. x.
Chloroform,
Tinct. opii
Tinct. camphoræ,
Spirit. ammon. aromat.....āā fl. ʒ vj.
Spirit. frument.....fl. ʒ jss.
One-half to one teasp onful as a dose.

POWDER FOR CORYZA.

Dr. Capitan offers the following formula:

℞
Salol.....grammes 1.
Salicylic acid..... " 20.
Tannic acid..... " 10.
Boracic acid (pulv.)..... " 4.
M.

At the beginning of the trouble a pinch of this powder is to be strongly drawn into each nostril, and the treatment should be given every hour for half a day.—*Bull. Pharmacy.*

ALLINGHAM'S OINTMENT FOR HÆMORRHOIDS.

℞
Bismuth. subnit.....ʒ j.
Hydrarg. chlor. mit.....ʒ ij.
Morphinæ.....gr. iij.
Glycerini.....ʒ ij.
Vaselini.....ʒ j.
M. Sig. Use in pile-p pe.

INDIGO AS AN EMMENAGOGUE.

Dr. Jones (*Le Bulletin Médical*, No. 82, 1891) has used indigo successfully in thirteen cases as an emmenagogue. He uses the following formula:

℞
Pulv. indigo.....grammes 8.
Bismuth. subnitrat..... " 2.
One-half teaspoonful three times a day for four weeks.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO. (Incorporated)

PROPRIETOR AND PUBLISHER.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.)

CHARLES K. MOUNT, Advertising Manager.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates),..... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts,.....$1.50 each.
Bovine Points or Quills,..... 1.00 a doz.
Humanized Crusts,..... 1.00 small.
Humanized Crusts,..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

☞Please accompany orders with the money, and address all communications to

The Butler Publishing Co.,
P. O. BOX 843. PHILADELPHIA, PA.

LEADING ARTICLE.

TYPHUS FEVER IN NEW YORK AND NORTH BROTHER ISLAND.

The typhus "scare" is by no means over in New York. New cases from entirely unsuspected quarters are continually cropping out, and North Brother Island is teeming with patients. The New York Board of Health has been laboring indefatigably, and the zeal of Dr. Edson cannot be too highly spoken of.

It is an open war between the deadly germ of typhus and scientific health regulations, and the result, merely from a scientific point of view, is of vast interest to the profession.

What is giving the New York Board of Health as much trouble at present as the typhus itself, is the untrustworthiness of many of its employes. The recent exposures of the *New York World*, regarding the utter lack of systematized work or precautions at North Brother Island, which accusations have been in the most part acknowledged by the physicians in charge and abundantly confirmed by the sworn statements of many nurses and attendants, are truly startling. Even when allowing liberally for the heightened coloring usually placed upon such reports by the modern newspaper reporter, there is, nevertheless, no getting around facts.

On the night the *World* reporters visited the Island, it is stated that one nurse had charge of 32 cases of typhus, and was unassisted, and that he was compelled to assist in the removal of the two patients who died during the night and was compelled to be absent from his patients for two or three hours. It is also claimed that his only instructions were a supply of stimulants, opiates and straps to be used at his own discretion. The straps were for delirious patients. True also that ward after ward was visited without finding any attendant or nurse.

But worse than this, all the attendants take their meals at one table in the same dining-room. Here measles, smallpox and scarlet fever nurses sit side by side with the typhus nurses. The regulation of wearing

gowns in the wards and removing them at meals has not been strictly enforced, and many nurses have come direct from their infected wards without change of clothing and mingled with the attendants of the other wards of diphtheria, measles, etc. Not even the washing of hands is required.

Another flagrant fault is that the diagnosing of suspected cases of typhus among the quarantined patients is largely left to an unqualified attendant, who merely takes temperatures, and only reports very high ones. The fact that typhus may exist for some time with a temperature of not over 100° reveals the possibility of the *World's* accusation as to several cases of typhus among the quarantined patients not having been discovered for 12 to 72 hours, being true.

These are only a few of the charges made against the management of North Brother Island, and which when the light of searching inquiry is turned upon them we surely trust will either be disproved or else speedily remedied if true.

In the enforcement of public health by the isolation of infectious diseases and quarantine, the authorities need the active assistance of the public, and to gain their assistance must first win their confidence, and the exposure of such conditions as have been reported to have been found on North Brother Island, can surely only win distrust and fear.

Who among the laity, aye, or even among the profession itself, would not hide their sick rather than to see them ruthlessly taken to a pest house, where they believe they will be exposed to infection from other diseases, illy cared for, and perhaps strapped to their mattressless cots while suffering with thirst or even dying? Humanity itself cries out against such a course.

The enforcement of Health Regulations at best would seem cruel to the uneducated public, and they should at least know that these stringent measures only mean greater care and comfort to the patients than that which they could possibly receive at home.

It is to be regretted that the investigations of the *N. Y. World* could not have been made by the proper authorities, and the faults prevented rather than discovered and checked; but for some unaccountable reason this is seldom done, and nothing remains but public exposure.

In conclusion we would say that we sympathize most heartily with the physicians of the New York Board of Health, and fully appreciate the difficulties which beset them, but at the same time we must commend most highly the unsensational, reserved and fair method with which our esteemed lay contemporary, the *N. Y. World*, has done its work; and, as has been said, we trust soon to learn that the serious faults now existing at the North Brother Island will be entirely remedied.

OBITUARY.

DR. D. HAYES AGNEW.

Dr. D. Hayes Agnew died at his residence in Philadelphia, on March 22d, after a brief illness.

Dr. Agnew was born in Lancaster county, Pennyslvania, in the year 1818, and received his early education at the Moscow Academy, in Chester county, at Jefferson College, Cannonsburg, Penna., and Newark College, Newark, Delaware. He received his medical education at the University of Pennsylvania and graduated in 1838. After receiving his medical degree he began the practice of his profession in Lancaster county, but after a short time he withdrew from the practice of medicine and engaged in the iron business. This venture proving unsuccessful he returned to Philadelphia and here resumed the practice of medicine, and at the same time began to teach anatomy at the Philadelphia School of Anatomy, on Chant street. It was here that he showed his great ability as a teacher, as was evident by the large classes of student which were drawn to his lectures and demonstrations from the University and Jefferson Medical Schools.

He was appointed Surgeon to the Philadelphia Hospital in 1854; Demonstrator of Anatomy and Lecturer upon Clinical Surgery in the University of Pennsylvania, in 1863 Professor of Operative Surgery in the same institution, in 1870; and in 1871 was elected to the position of Professor of Principles and Practice of Surgery in the University of Pennsylvania, which position he held until 1889.

Dr. Agnew laid the foundation of his great reputation as a teacher of anatomy in the Chant Street School, and it was here that he trained himself as a practical anatomist; a training which fitted him to conduct in a most brilliant and successful manner the extensive surgical practice which afterwards fell to his lot.

Dr. Agnew also served as Surgeon to the Wills' Eye Hospital, the Orthopædic Hospital, the Pennsylvania Hospital, and as Honorary Surgeon to the Presbyterian Hospital.

Dr. Agnew's great work upon Surgery, the preparation which occupied some of the busiest years of his life, remains as a monument to his industry and acuteness as a clinical observer.

As a teacher of anatomy and surgery Dr. Agnew was noted for the clearness of his teaching, and those of us who had the fortune to attend his lectures can recall with pleasure his clear and forcible exposition of the subjects which he treated, and this was nowhere better shown than in his lectures upon hernia, fractures and dislocations.

As an operator he was most graceful and skilful, having the rare faculty of using either hand with equal facility; the writer has frequently seen him shift his knife from the right to the left hand in the operation of lithotomy. It would be impossible to note the many operations in which his skill as an operator was demonstrated, but it has always seemed to us that in no operations was his delicacy of manipulation more clearly shown than in the removals of tumors from the neck and in the ligation of arteries in their continuity. As a diagnostician he possessed rare ability, the accuracy of his power in this respect in the diagnosis of abdominal disorders being most remarkable.

That all important attribute of a surgeon, good judgment, he possessed in an extraordinary degree, and it was this characteristic combined with his personal attributes which made him so popular as a consultant.

He possessed a personality which was characterized by dignity, honesty and straightforwardness, and all who came in contact with him were impressed with his Christian character and kindly disposition.

No member of the profession was dearer to his professional brethren, no one was more loyal to their interests than Dr. Agnew, who lived and died possessing their universal respect and admiration.

Twice in life we are proud of our years—in early youth and extreme age.

BOOK REVIEWS.

TRAITÉ DE MÉDECINE: *Publié sous la direction de* Mm. Charcot, Bouchard *et* Brissaud. *T. 1, Paris. G. Masson, 1891.*

The first volume of the Treatise on Medicine published under the gereral direction of Professors Charcot and Bouchard, and edited by Professor Brissaud, includes the infectious diseases, the natural history of the microbes, and their relations to disease, prophylaxis and treatment.

We hardly have realized yet, so rapidly has the microbian theory grown to be part of our mental equipment, a thing assumed and accepted, how recent its beginnings are, until such a work as this imposing volume reminds us of it and recalls how it was only yesterday, so to speak, that we discussed and doubted, while to-day the world of science has accepted it in its general outlines, and but waits while the empty spaces are filled in hour by hour with the details.

The historical review with which M. Charcot opens the Treatise shows how the seed was planted when Pasteur, in 1857, submitted his memoir on lactic fermentation to the Academie des Sciences of Paris, completing the demonstration for which the work of Billing and Liebig had prepared the ground.

In the paper the great French student announced clearly the principle of the action of ferments: "Fermentation is the correlation of the life, of the organization of the cells, not of their death or putrefaction," and at the same time created the method of successive cultures which allows us to isolate, to evolve these microscopic creatures in inert media. Chauveau, ten years after, studying vaccinia, variola and sheep-pox, found that their active principles were the corpuscular elements which remained on his filters, not the liquid which passed them, and predicted the course which the work of the future would take. Then followed Pasteur's discoveries in anthrax, and the studies of Koch and Klein. It is within the last five years that a partial distinction has been established between toxic and vaccinating substances, a distinction to-day sufficiently firmly settled.

The life history in general of the microbe is next taken up, and this is followed by a remarkably clear and interesting chapter on the etiology of bacterial diseases, including the homes of the germs in the earth, air, and water, in different fluids, animals and vegetables, and how they penetrate the human economy, reviewing in turn the modes of contagion and inoculation, the virulence of

secretions and excretions, the shares taken by food, drink, environment, heredity, age, sex, race, temperament, cold, heat, occupation, auto-intoxication and secondary infection.

Next the author proceeds to the symptoms of infection, the mechanism, the general pathological anatomy, and the manner of recovery or death.

While every portion of the immense field suggested by this synopsis could not possibly be covered in a single chapter, since almost any one of the subjects might well claim a volume, yet nothing has been slighted, and still more noticeable is the constancy with which the authors have kept before them the central principle announced in the preface—"Begin wherever you can from the clinic, but return always to the clinic"—a principle not always kept before the bacteriologist.

Where the facts are well recognized they are stated succinctly, perhaps the chief authorities are given (with a slight preference, naturally enough, in favor of the French ones), their experiments and the reasoning from them briefly detailed—and the application to clinical uses and studies at once made. If the matter is too uncertain to be of clinical service, or altogether doubtful, as for instance the counter-influence attributed to bacterium termo in tubercular disease, it is dismissed with the shortest mention. A part worth the study of the "practical man" who despises laboratory work is that on immunity from infection, natural, as in the resistance of the carnivora to tubercular disease, or acquired, as in the process of vaccination. No intelligent thoughtful man could read it, whatever his views of "pure science" and not see how vast the field it opens, how entirely practical the conclusions, and how stimulating to the scientific imagination the vista of future possibilities.

The first division of the book ends with a summary of the general indications for treatment in disease of bacterial origin, which the studies of the modes of entrance, life, action and death or removal of the microbe suggests: "In the course of bacterial affections it is necessary to act upon the *kidney*, which eliminates germs and toxic principles; *diuresis* is of service in this direction, as the study of the urinary crisis proves. It is necessary to act upon the *liver*, which destroys, retains or transforms part of the poisons. To this end we must strive against *hyperpyrexia*, because among other evils, suppressing or lessening the glycogen of the hepatic gland, it thereby annuls the functions of this organ. *Nourishment*, even excessive feeding will favor this action of the liver-cell and will give to the organism new energy for the struggle against the parasites, and resistance to their attacks * * * * * *Oxygen* aids combustion: the more certain toxic principles are oxidized, the less harmful they become. *Pure air*, frequently renewed and the various nervous stimulants should be used to sustain and excite the forces of the patient. Its good influence upon tuberculous sufferers is well known."

Nutriment in the diatheses and in disease is next treated, and obesity is considered at some length, with a discreet review of the numerous "cures," ending with this Gallic conclusion—"The obese patients from whom the readiest evidence to our prescriptions is obtained * * are * * * * women whose personal attractiveness is at stake, above all a widow desirous of still charming."

The article on diabetes has a particularly good history of the innumerable drugs at various times recommended in this affection, but some for good reasons not of service, some of unaccountable usefulness. They make a much longer list than the twenty-seven theories of the cause and mechanism of diabetes, which, in 1880, Bouchard stated had been put forth up to that date. Several have been born since. The paper on gout which follows contains no new matter, and is little more than a "précis" of the classical English works on a subject which the English have made peculiarly their own.

In the next section one looks with interest for the newest thought and discovery since its subject "infectious diseases common to man and animals" includes the three maladies, anthrax, glanders, and rabies, from which the science of bacteriology has learned most of its lessons. M. Roger has accordingly given a large share of his attention to these, which may be called the prototypes of the maladies which we bear in common with the beasts, but our debt to the comparative pathology of tetanus and tuberculosis is scarcely less, and these are studied at length too, although the author, holding only to demonstrated facts, concludes that but five affections are contracted purely from animals—vaccinia, anthrax, glanders, rabies, and trichinosis. Others are produced in man and animal by the same pathogenic agent, but contagion, while it may occur, is not a necessity. Such, among others, are tuberculosis, tetanus, and actinomycosis. A separate section is given to typhoid fever, and then come the infectious diseases whose pathogenic agents have either not been isolated like grippe and dengue, or not proven, like mala-

rial fever and yellow fever. M. Roger gives in detail the successive steps in the recognition of the bacillus anthracis from Rayer's description, in 1850, of "small filiform bodies in the blood [in anthrax] of about double the length of a red corpuscle," through the work of Delafond, Davaine, and others, to its completion by Koch and Pasteur in 1876–77—the first clearly proved bacterial disease. The rest of the story every one knows, and knows too that we have not learned much from all this labor—the relative proportions are not unfairly shown in the distribution of matter in the article—thirty-eight pages of history and pathology, two pages of treatment. It would be unjust not to add that we have gained a much more important knowledge—that of prevention.

Perhaps to this country the practical value of the next subject, glanders, is greater than that of the studies of anthrax, for while the latter is an exceptional disease on this continent, the former is unhappily common in its equine form—so common that probably a veterinarian in active practice in Philadelphia could point out a dozen cases any day. Considering its easy experimental transmissibility, it is curious that the clinician sees it so rarely in the human subject. But its frequency and virulence among horses is enough to render its study of the greatest economic importance. M. Roger does not display quite the same fairness here which we noted above, for he speaks as if the final discovery of the bacillus of glanders were due to his countrymen, Bouchard, Charrin, and Capitan, though the credit incontestably belongs to Loeffler and Schutz, and it is to the former of these that we owe the greater part of our knowledge of the whole history of this bacillus.

The difficulty of diagnosis is strongly insisted upon, but scarcely enough stress is laid on the ease of proof by test-inoculations producing characteristic lesions, notably a peculiar orchitis in guinea-pigs. It would be well could our own state lay to heart the strong expressions of the writer on the prophylaxis and sanitary policing of the disease, since we are really without a law on the subject.

Rabies is a disease in whose study the French have an incontested pre-eminence. The article on it here has made good use of the vast material offered by the Pasteur Institute. The first human patient whom Pasteur treated was a lad, Joseph Meister, who had received so many and such severe bites that his death seemed certain. At the time of writing, six years after the inoculation, his health was still perfect. The utility of the treatment has since been demonstrated in more than 8,000 patients treated at Paris, a number which may be doubled by adding those treated at the Pasteur Institutes of other countries.

In tuberculosis, too, a large share of the honor must fall to French observers, for although the extraordinary completeness of Koch's work is shown by the fact that no important addition has been made to his statements published in 1882 and 1884, it was Laennec who earliest insisted upon the "unity of phthisis," a theory to which Virchow and Niemeyer opposed all the force of their convictions and teaching.

A conservative opinion of a very moderate kind is expressed as to the possible value of "tuberculin":—"Its application to man was made in too hasty a fashion. It must go back to the laboratory from which it should never have emerged. But while they must still remain in the field of experiment, the importance of Koch's researches cannot be denied: the curious properties of the lymph, its action upon the tubercles, the changes which it brings about in their surroundings, are all facts of great interest."

Professor Chantemesse has made a singularly interesting contribution to the volume in his article on typhoid fever. The definition with which it opens may be quoted, both to show how far from the cut-and-dried style of the text-book is the author's manner of treating his subject, and as an example of the modern attitude from which the whole matter is regarded:—"Typhoid fever is a general disease, the result of the reaction of the economy against the invasion of the typhoid bacillus. This definition rests upon the symptoms and ætiology. It leaves out of the question the pathological anatomy; the intestinal lesion is not the characteristic of the disease; and it implies the idea of generalized infection. A local change, even though the result of the typhoid bacillus, is not sufficient to constitute typhoid fever."

M. Chantemesse mentions the paper of our townsman, Gerhard, as one of the earliest contributions to the separate history of typhoid, confused with the other continued fevers until the clear descriptions of Louis, whose pupil Gerhard had been, but he does not say that this study (*American Jour. of the Medical Sciences*, 1837) was the *first* in any language in which the distinctive differences were fully and sharply made out.

So much of value is contained in the article that it is difficult to select anything to quote. The importance of the studies of the

bacillus which have demonstrated its amazing vitality cannot be overestimated. It flourishes damp or dry, warm or frozen, with or without oxygen, above or below ground, and sunlight and acids appear to be almost the only things which it finds inimical—a hint for treatment. It has been found in the course of the disease in nearly every organ and tissue of the body, and indeed it is probably to its very constant presence in the lungs that the frequency of pulmonary symptoms, bronchitis, congestion, and pneumonia, in the course of the fever is due.

Numerous experiments show that a typhoid case may spread infection by fæcal matters, by the urine, especially if albuminous, and by the sputa. From these facts the means of prophylaxis are deducible.

The influence of drinking-water in the propagation is discussed at length, and many conclusive instances are cited, none more remarkable than the history of the Plymouth epidemic in Pennsylvania. Complete demonstrations are occasionally made by the periodic epidemics which in Paris always follow when for any cause the Seine water has been used for the public supply. This species of "vivisection" of human beings on a vast scale we are familiar with in our own city, and the tax we pay for the knowledge runs annually to a sum of thousands of cases and hundreds of deaths. A valuable practical point is given in disinfection. Richard and Chantemesse repeated with similar results the experiments of Laborius and Pfühl on the value of milk of lime as a disinfectant. "Milk of lime" made with slacked lime in 20-100 solution proved superior to 1-1000 sublimate and to chloride of lime, absolutely putting an end to the growth and life of the bacilli in a few minutes. It possesses the advantage of a nominal price, of being harmless, and of being useful in small quantity, namely, 2 parts to 100 of the fæces or fluids.

The hydropathic therapy of Brand is advised or Bouchard's modifications, which consist in gradually lowering the bath temperature, the routine use of a purgative every third day, and intestinal antisepsis by naphthol and salicylate of bismuth.

The report of the director of the Council of Health is quoted as saying that Brand's treatment "gives a regiment to Germany every three years."

Space fails to consider the remaining articles on influenza, malarial fever, cholera, and yellow fever.

The Frenchman has the art of expressing himself with grace and ease, and none of the authors fail in this respect to reach the national standard. A clear and flowing style is a grace all too uncommon in medical work, but here this excellence combines with simplicity of statement to render the treatise most agreeable reading. A vast amount of information and study, scattered in a thousand journals and pamphlets, has been carefully brought together, and sifted to its useful elements, all views getting a fair representation, while the several distinguished authors add to their values by their own comments and opinions.

Five volumes more are promised at short intervals. It is to be hoped and expected that they will be as good as the first.

LITERARY NOTES.

THE COSMOPOLITAN FOR APRIL.

With the April number, the *Cosmopolitan* completes its twelfth volume in a manner worthy the wide and growing popularity of this magazine. The *Cosmopolitan* is the most superbly illustrated of the monthlies and the pictorial embellishment of the April number is rather above the average. The leading article is on "Genoa—the home of Columbus" written by Murat Halstead who recently visited the city, and illustrated from photographs of all the principal relics of the great navigator which remain in Genoa. "A romance of old shoes," by Miss Elsie Anderson de Wolfe, exhibits the best of the remarkable historical collection at Cluny. "Torpedoes in Coast Defence" is the title of a timely paper by Lieut. A. M. D'Armit of the U. S. Army with photographs and drawings by J. O. Davidson. Wallace Wood treats of "Homes of the Renaissance" in an illustrated paper, and William H. Rideing, is the author of a delightfully written and profusely illustrated article on "The Crew of a Transatlantic Liner." "The Marriage of American Women to German Noblemen" is discussed by Elizabeth Von Wedel, an American who is now the wife of a titled subject of the Kaiser. Other papers are "The Theatre of To-day" by Cora Maynard; "Two Englishmen of Letters," by Brander Matthews; "All Sorts of Conditions of Men" by Edward Everett Hale; "A Living Opal" by Ernest Ingersoll, and "Count Leon Tolstoi," a description of the family life of the great Russian novelist and reformer by a friend of his family. Beside all these attractions the April *Cosmopolitan* is rich in fiction and poetry. "The Rancho of Heavenly Rest" is a vigorous sketch of the southwest, full of action and local color.

Its writer is Forbes Heermans, the author of "Thirteen" and more stories. The illustrations are by Irving R. Wiles. "Princess Ratazánoff" by Cassimer M. Podgorski, is a characteristic tale of Russian Court life in the days of the Czar Paul I. Frederic Remington has illustrated delightfully "The Rustic Dance," a poem by Irving Bacheller, and other verses have been written for this number by George Macdonald, Katherine Lee Bates, Charlotte L. Seaver and Sarah M. B. Platt.

THE LITERARY EDITOR.

The book-reviewer on the staff of a daily newspaper is commonly known as its literary editor, though, as a matter of fact, he is seldom a literary person. Moreover, his duties are determined by the character of the organ he serves: it seems to be worth the while of comparatively few journals in the United States to employ a competent critic solely for the purpose of telling its readers about the contents of new books. In most cases this function is performed perfunctorily by the musical or dramatic editor, who, in turn, is simply an industrious, enthusiastic, or overworked member of the writing force,—perhaps a writer of "editorials," perhaps not. At all events, it is folly to designate him as a literary editor or as a book-reviewer; he edits nothing; he is first and last a drudge, capable, perhaps, of something better than hack-work, but productive of that alone. Then there are first-class journals which send out some of the more important books for review to special writers, and dispose of the great body of new publications in brief paragraphs,—vastly to the disgust of the publishers and authors. Or the various members of the staff are periodically taxed for lengthy notices of the larger works, and the remainder is comprehensively condemned in a sporadic half column or so of "literary notes" by the exchange editor. Finally there is a small group of journals which have found it to their interest or profit to make a "feature" of adequate book-reviews, edited and for the most part written by a single "literary editor." He may, to be sure, do other things,—pass upon contributed verse or manuscript of a general literary character, select the miscellany from magazines, help in the make-up of the Sunday supplement, write the obituaries of distinguished authors, and contribute a fixed or irregular quantity of "editorials" during the week; but these odds and ends are quite by the way; he is first and foremost a reviewer of new books.

The life of such a one, if he would have it so, is the most tranquil in journalism. He will do a large part, and it will be the better part, of his work at home. At the office, only the occasional visit of a passionate poet, manuscript in hand, or of a nervous author eager to indicate the particular merits of his printed work, will disturb the reviewer's communication with current literature. His professional adventures are of the mildest sort.—*Melville Phillips, in April Lippincott's.*

PERISCOPE.

THERAPEUTICS.

THE INDICATIONS FOR QUININE.

Manquat (*Lyon Méd.*, October 25th, 1891) gives a summary of the indications for quinine. In *malaria* it is efficacious in all types, besides being a preventive. Laveran showed that malarial microbes disappear from the blood after quinine has been taken for a certain time, and that the addition of a minute quantity of a weak solution to malarial blood destroys them. He considers the white blood corpuscles are not directly influenced, but enabled more easily to subdue and seize upon the micro-organisms rendered dead or moribund by the drug. If given during or just before the onset of an attack, quinine has no power to check it, while this may be prevented if taken at a sufficient interval beforehand. Baccelli made intravenous injections of 1 g. during the onset, but during the first six hours could recognize no modification in form, number or movement of the microbes. As the largest part of a given dose of quinine is eliminated during the sixth hour after injection, while according to Laveran it is during the onset that the microbes are present in the blood in greatest number, the drug should be given at an interval of about six hours before an expected attack. Quinine should be taken eight hours before shivering appears in quotidian ague, twelve hours before in tertian, and from eighteen to twenty-fours hours beforehand in the quartan variety. To these figures, however, another hour should be added; half an hour on account of the tendency of the onset of successive attacks to be antedated to that extent, and half an hour as allowance for imperfect absorption from impaired gastric action. For the last reason also, and to obviate its rejection, the required quantity should be given in two or three divided doses at half-hour intervals. Two

doses, eight to ten hours before the expected onset of shivering, are almost always effectual. If the result be unsatisfactory, an aperient should be given. Laveran states that no microbes are found in the blood of malarial patients after sulphate of quinine has been taken for eight days in doses of 0.6 to 0.8 g.; but that if after three or four doses it be discontinued, the microbes reappear, and a relapse occurs. Upon this is based his scheme of treatment, namely: During the first three days, 0.8 to 1 g. of hydrochlorate of quinine daily. No quinine during the fourth, fifth, sixth and seventh days. On the eighth, ninth and tenth days, 0.6 to 0.8 g. None from the eleventh to the fourteenth day. On the fifteenth and sixteenth days, 0.6 to 0.8 g. None from the seventeenth to the twentieth day. On the twenty-first and twenty-second days, 0.6 to 0.8 g. In very severe cases recourse should be had to hypodermic or intravenous injection, or injection into the respiratory tract. A gramme of a salt of quinine may be injected subcutaneously, and repeated after a short interval; as a rule, 1½ to 2 g. are sufficient. The injection should be made into the deep subcutaneous tissue to avoid complications. The following formula may be used: ℞ Quin. sulph. 1 g., acid. tart. 0.5 g., aq. destill. 10 g. The addition of a little antipyrin greatly enhances the solubility; 1 g. quin. hydrochlor., with 0.5 g. antipyrin will dissolve in 2 g. of water. When with severe depression there is reason to believe no absorption has taken place, the solution may be injected into the trachea through the crico-thyroid membrane. Baccelli recommends intravenous injection as the most prompt and efficacious method in very grave cases (quin. hydrochlor. 1 g., sodii chlor. 0.75 g., aq. destill. 10 g.). The solution should be injected very slowly into one of the small venous branches at the bend of the arm. In continued malarial fevers quinine must be given in larger doses. Laveran advises 1.5 to 2 g. daily (0.6 morning, 0.8 evening), till fever disappears. This nearly always happens by the second or third day. If fever persists with four days' treatment, it may be assumed to be non-mlarial. When the temperature falls, 0.6 to 0.8 g. should be given daily for a short time. In malarial cachexia quinine wine may be taken with meals, but not fasting, or long before food, otherwise gastralgia and dyspepsia ensue. As a preventive, quinine is not effective in smaller doses than 0.25 to 0.30 g. It should be given also in all malarial complications and incidental affections (for example, neuralgia, hæmorrhage, pneumonia). In *typhoid fever* Jaccoud and others restrict its use to certain conditions, namely, non-remission of fever, or very slight morning remission; an uninterrupted series of evening temperatures over 104°; cardiac failure. In *pyœmia* quinine in large doses (1 to 2 g.) is the only remedy which has been in some measure successful; but as it has often failed when given alone, a definite conclusion as to its value cannot yet be drawn. In *acute articular rheumatism* it has been frequently given with success, but is of much less efficacy than the salicylates or antipyrin. In *Ménière's disease* quinine has been given with some success in daily doses of 0.6 to 0.8 g. for one or two weeks, followed by discontinuance for an equal period, and then by renewal of similar treatment. The first doses appear to cause exacerbation of the symptoms, and must be continued for some time before improvement occurs. In *blennorrhagia*, tepid 1 per cent. injections of sulphate of quinine have proved of marked success. Rapid improvement began from the first, and continued till the fifth day, when as a rule only a drop of cloudy discharge appeared. Complete recovery did not, however, ensue for some little time (quin. sulph. 1 g., bism. subnit. 5 g., mucilag. 10 g., glycer. 30 g., aq. destill. cal. 120 g.—Jullien). Regarding the mode of administration of quinine generally, the sulphate, though most often used, is less suitable than the hydrochlorate, which is more soluble, contains more quinia, and is less subject to mould. A solution of 1 in 20 is very useful, but very bitter. On account of this, and its concentration, it is well to prescribe half a tumbler of some drink afterwards; coffee is a good menstruum. For rectal injection, the desired quantity of quinine should be dissolved in 100 to 120 g. of tepid water. If opium is not contra-indicated, the addition of 10 g. of laudanum is useful. The injection should be preceded by a simple enema.—*Brit. Med. Jour.*

TREATMENT OF TYPHOID FEVER.

Dr. Smakowsky (*Ugskrift for Lœger*, Nos. 34–35, 1891), in a hospital practice of some 700 cases of typhoid fever, has had opportunity to try all kinds of treatment. He has found Prof. Sacharjin's method of treating the disease with divided doses of calomel the most efficacious. One-half centigramme (one-tenth grain) of calomel, mixed with sugar, is given every hour until copious purgation takes place. Frequent gargling with chlorate of potash will prevent the appearance of stomatitis. In cases where there are already

signs of heart-weakness an infusion of digitalis may precede the calomel treatment. If this treatment be instituted during the first week of the disease one will seldom fail to cut it short, even where it appears with violent symptoms. If it fails in this, the course of the disease will be shorter and the complications milder. This treatment may be repeated, for the second course will sometimes show an improvement which the first will not. In those cases which are not aborted the writer advises the use of the following powder:

℞ Bismuthi subnitrate.....dgm. 10 (grs. jss).
Naphthalin.....cgm. 20 (gr. ⅓).
Quiniæ sulphat.....dmg. 10 (grs. jss).

Sufficient for one powder. One powder four times a day.

If lung symptoms be present he prescribes:

℞ Spirit. ammoniacat. anisat...gms. 4 (fl. 5j).
Tinct. eucalypti.....gms 30 (fl. ℥j).
Tinct. menthæ pip.....gtts. x.

Ten drops every second hour.

This is an excellent disinfectant for the mouth. If this method can be instituted before the tenth day, the patients are not weak and debilitated individuals, and where there are no very severe complications the mortality will be exceedingly small. He has observed fourteen cases where the disease was aborted immediately after its beginning by the calomel treatment. He has also found treatment by calomel of service in recurrent and petechial typhoid.—*Cinn. Lancet-Clinic.*

TREATMENT OF EPILEPSY BY THE CONJOINED EMPLOYMENT OF BROMIDE OF POTASSIUM AND OF AN AGENT CAPABLE OF RENDERING THE NERVOUS CENTRES ANÆMIC.

Under this head Poulet, of Planche-les-Mines, writes of a combination of bromide of potassium with calabar bean (*vide Medical Times*, vol. v., p. 610), which has given him success in the treatment of obstinate cases of epilepsy, where the bromides alone had failed. Dose: One tablespoonful, to be increased to a tablespoonful and a half, then two tablespoonfuls, daily. A tablespoonful contains about 57 grains of bromide and about 16 minims of the tincture. The medicine may be given in divided doses instead of one full dose, half a teaspoonful being given at first twice, then three times, then four times daily. The bromides remain the sheet anchor in epilepsy; and by the term "bromides" we have especial reference to the bromide of potassium, which alone is truly efficacious. There are, however, a great many epileptics whose attacks are only mitigated or postponed, not completely suppressed, by bromide of potassium, and in such cases, if we associate the bromide with some agent that possesses properties identical with those of the bromide (that is, being capable of anæmiating and decongesting the nerve centres and paralyzing the system of voluntary muscles), we generally obtain results which are perfectly satisfactory in essential epilepsy, and even in partial, or Jacksonian, epilepsy, on condition that, in the latter, we begin by the specific treatment of the determining cause. The substances that have been most successful are calabar bean, picrotoxine, and belladonna. In cardiac epilepsy digitalis must be added. We may indifferently substitute sulphate of eserine for the preparations of calabar bean, sulphate of atropine for those of belladonna, and digitaline for digitalis.—*American Journal of Medical Science*, September, 1891.

MEDICINE.

ALBUMINURIA IN SYPHILIS.

At a meeting of the Russian Syphilidological Society, Dr. Oscar V. Petersen, of St. Petersburg (*Vratch*, No. 21, 1891, p. 511) stated that, while conducting an inquiry into visceral syphilis (*ibid.*, No. 32, 1887), he was struck with the fact (1) that of 88 necropsies of syphilitic bodies, in 34 renal lesions were present; and (2) that of 36 cases in which the fatal issue had been caused by syphilis itself, in 7 the patients had succumbed mainly to chronic nephritis. In view of figures he undertook a systematic examination of the urine in 200 consecutive cases of syphilis, all of which were treated by intramuscular injections of salicylate of mercury, from 0.1 to 0.13 g. once weekly. The urine was examined—invariably after two methods: boiling and nitric acid, and after Esbach's rules—once after the patient's admission and subsequently once every week, usually on the next day after the mercurial injection. The grand total of the analyses amounted to 1,141, of which 436 referred to 78 patients with recent syphilis; 615 to 103 with secondary lesions; and 90 to 19 with late manifestations. In 55 (27.5 per cent.) albuminuria was found; of these, 28 (35.9 per cent.) belonged to the first category; 22 (21.3 per cent.) to the second; and 5 (26.3 per cent.) to the third. Of the 55 cases, in 28 a spurious albuminuria—that is, depending on an accidental admixture of proteids in patients with purulent balanitis, gonorrhœa, prostatitis, etc.—was present, occurring in 18 patients with recent syphilis, seven with secondary, and three with late disease; in 19 (6.8 per cent.)

a transitory one, affecting seven patients of the first group, 11 of the second, and one of the third; and in seven (4.2 per cent.) a genuine permanent or "syphilitic" albuminuria (in three recent cases, four secondary cases, one late). Dr. Petersen's conclusions may be summarized as follows: (1) In all syphilitic cases admitted to hospital the urine should be examined immediately after admission; (2) a genuine albuminuria should be strictly differentiated from a transitory or a spurious variety; (3) syphilitic albuminuria occurs in about 3.8 per cent. of patients with recent syphilis, 3.8 of those with secondary symtoms, and 5.8 of those with late manifestations; (4) in syphilitic patients with nephritis, a mercurial treatment readily gives rise to lesions of the gums, hence whenever sponginess of the gums appears in a syphilitic patient the urine should immediately be examined; (5) the salicylate treatment may sometimes produce transitory albuminuria; such cases, however, are very rare, and the symptoms soon disappear; (6) the elimination of mercury by the kidneys never causes a genuine albuminuria, and generally does not irritate the organs; (7) on the contrary, syphilitic albuminuria is rapidly cured by the use of mercurials.—*Brit. Med. Jour.*

BILATERAL PARALYSIS OF THE SIXTH NERVE.

The minute study of the nerves of the eye has been shown to be of importance from its bearing on the knowledge of the diseases of the central nervous system, and from this point of view at least the rare condition of bilateral paralysis of the external recti muscles of the eye deserves attention. In the large *clinique* of Landolt, M. Dufour has found three examples. In the first case (*A*) a man, aged fifty, had felt the annoyance of diplopia for some time. After careful examination it was found that the only abnormality of the muscles of the eye was a paralysis of the external rectus on both sides, which led to a convergent strabismus of about 35°. In general health he complained only of a want of energy; but it was noticed that both his pupils were very small and reacted very little to light though well to accommodation. The knee-jerks were normal, but he found it difficult to stand with his eyes shut. In the second case (*B*), a woman of fifty-four, Landolt had observed, twelve years before, a paralysis of the third nerve on the left side, which lasted some time; and again, a year later, a paralysis of both the sixth nerves which was only temporary. The same bilateral paralysis reoccurred again after nine years, and this time had lasted apparently unchanged for two years. The retinæ were normal, the pupils insensible to light and acting very little to accommodation. The third case (*C*), a man aged thirty-eight, had a history of good health in all important points. Two years before he had some diplopia for a short time; at present he was suffering from a more serious attack, and had convergent strabismus of 25°. There was paresis of the external recti of both eyes. Vision was good, and the ophthalmoscope showed no abnormality. His general health was poor, and his legs were weak. There was no knee-jerk on either side, and he could not stand with his eyes shut when his heels were brought together. In these three cases the conclusion to which the bilateral paralysis of the sixth nerves points is that there was a central lesion brought about by some chronic cerebro-spinal disease, such as locomotor ataxy. Duchenne had remarked that in the earlier stages of locomotor ataxy some paralyses of the muscles of the eye occurred which were only temporary; and this agreed with the previous history of two of these cases.—*Le Progrès Méd.*, p. 171, September 5, 1891.

DIAGNOSIS OF BLADDER TUMORS.

Dr. Guiard points out some features of hæmaturia which may aid in establishing the diagnosis without digital examination or exploratory incision. Prostatic tumors are scarcely ever accompanied by hæmaturia; renal tumors very generally are. Renal hæmorrhage is quite often only of short duration, small in amount, and recurs at long intervals. At times there is an alternation of clear and bloody urine in the same day, a condition never seen in hæmorrhage due to tumors in the bladder. Renal hæmorrhage gradually diminishes and finally disappears. The opposite is seen in bladder tumors. In washing out the bladder if the last drops consist of pure bright blood, it speaks for tumor of the bladder. Elongated clots, rarely found, are probably formed in the ureter, especially if pains like renal colic have preceded their discovery. Small blood cylinders may be casts of the efferent kidney tubes. Hypogastric palpation alone usually shows nothing, but after the bladder has been emptied Guyon's method of *ballottement* shows the smallest increase in the size of the bladder. By pressing the anterior hand deeply with successive expirations, the extent and thickness of a bladder tumor can be appreciated.—*Archives Générale de Médecine*, October, 1891.

A RARE PARASITE.

With reference to the records of distoma crassum which have been published, we find, on consulting the pamphlet in which Dr. Sinclair published his paper, that the statements there made is that "distoma crassum or Sinense with anchylostoma were present in one case." It would be interesting if Dr. Jacob would describe the specimen, which we understand is now in the Museum of the Leeds Medical School, or state positively which species of distoma, whether crassum or Sinense, Dr. Sinclair alludes to, so that the case may be recorded as an additional instance of the occurrence of one or other of these parasites.—*Brit. Med. Jour.*

ANGINA PECTORIS.

Dr. R. Douglas Powell believes angina pectoris to be the expression of a disturbed innervation of the heart or the vessels associated with more or less intense cardiac distress and pain, and a general prostration of the forces, always producing anxiety and often amounting to a sense of impending death. Considerable stress on habitual high arterial tension as a factor in causation. The affection is not necessarily associated with coronary or other disease of the heart or vessels, although in fatal cases, disease or obstruction of the coronary arteries is the most frequent lesion found, after which, in order of frequency, come fatty degeneration, aortic dilatation, aortic regurgitation, and aneurism. The varieties of the affection are classified as follows: (1.) In its purer forms we observe disturbed innervation of the systemic or pulmonary vessels, causing their spasmodic contraction, and consequently a sudden extra demand on the propelling power of the heart, violent palpitations, or more or less cramp or paralysis ensuing, according to the reserve power and the integrity of that organ.—*Angina pectoris vasomotoria.* (2.) In other cases we have essentially the same mechanism, but with extra demand upon a *diseased* heart.—*Angina pectoris gravior.* (3.) The trouble may commence at the heart through irritation or excitation of the cardiac nerves, or from sudden accession of anemia by the cardiac muscle from coronary disease.—*Primary cardiac angina.* (4.) In certain conditions the blood (often gout), or under certain reflex excitations of the inhibitory nerves always, however, with a degenerate feeble heart in the back-ground. We may observe intermittence in its action prolonged to syncope.—*Syncopal angina.*

Regarding treatment.—In group 1, nitrite of amyl, and still more nitro-glycerine are of great value, and may be combined with nervine tonics or sedatives, iron, zinc, valerian, bromides, etc. In groups 2 and 3, carminative stimulants, or digitalis with nitro-glycerine, are recommended, and of all tonics, arsenic, as a rule, is the best.—*American Journal of Medical Science.*

NEUROSES AND NEURO-PSYCHOSES AFTER TRAUMA.

Dr. Schultze presents the following conclusions on this subject: 1. There are various psychoses and neuroses which may be caused by a traumatism, but not a definite disease to which the name, traumatic neuroses, is applicable. 2. The symptoms regarded by Oppenheim as pathognomonic of traumatic neuroses, viz., (*a*) concentric contraction of the visual field for white and for colors, and (*b*) partial or diffuse anæsthesias, are absent in many cases of functional disease after trauma and are not characteristic. 3. The traumatic neuroses are not of rare occurrence, and when developed after trivial injuries are apt to be the result of simulation and aggravation. 4. Positive objective criteria for determining the existence of, or non-existence of simulation are not at present in our possession.—*Volkmann's Vortrage.*

ANÆMIA AND HYPERÆMIA OF THE BRAIN IN THEIR RELATION TO EPILEPSY.

Z. Gutnikow (*Pflüger's Archiv,* xlix, p. 609) has made some experiments on this subject in animals. If an animal be fixed in a radiate direction upon a centrifugal apparatus, according to Salathé, when the head of the animal is at the periphery, on rotating the apparatus hyperæmia of the brain intervenes, but when the head is at the centre and the legs directed towards the periphery of the disc of the apparatus, anæmia of the brain occurs, and in the latter case the animals die more rapidly. Gutnikow, in repeating these experiments, comes to an opposite conclusion. In the case of guinea-pigs rotated on a centrifugal apparatus, he finds that when the head of the animal is directed towards the periphery of the disc, there is cerebral anæmia, and in the opposite case hyperæmia; but this occurred only in animals which survived. Dead guinea-pigs exhibit the phenomena described by Salathé. In the latter case centrifugal force effects its usual action, but in living animals the influence of the vasomotor centre opposes and

even overcomes the action of the centrifugal force. It is well known that excision of a portion of the sciatic nerve in guinea-pigs may be followed by epileptic seizures under certain conditions. In animals already suffering from epilepsy, when they are placed on a centrifugal apparatus and rotated, the epileptic attacks are increased when the head is placed towards the periphery. If the animals were not subject to epileptic attacks then rotation induced such attacks.—*Brit. Med. Jour.*

A CASE OF CHOLEDOCHOTOMY.

Prof. E. Küster reports a case of gall obstruction and jaundice in a woman 48 years old. She had suffered for two years and had been already icteric for months. Küster, from the symptoms, diagnosticated presence of stone in the common duct. The operation showed this diagnosis to be true. He found the gall bladder shrunken, the common duct very much dilated and containing several stones. The common duct was incised and several calculi removed. The wound was closed by a double row of sutures and tamponed with iodoform gauze. With the exception of considerable secondary hæmorrhage the recovery was complete. This is not the first case. Another case is reported by Kümmel; yet another by Courvoisier, in all five cases, so that we have six cases with one death and five recoveries. The application of this operation is entirely circumscribed. The cholecystenterotomy of Winiwarter will not be entirely replaced by this operation. Rehn, of Frankfort-on-Main, had, in a similar case to that reported by Küster, extirpated the gall bladder, after which he found several biliary calculi in the common duct, which he removed by incision. Sutures-recovery. Braun, of Konighberg, reported a case in which he, after separating the adhesions and fixed the shrunken gall bladder against the duodenum, discovered a large sized biliary calculus in the common duct, which by means of incision was removed. The wound was closed by four sutures, tamponed by iodoform gauze, and an uncomplicated recovery ensued. After seven days bile appeared in the intestinal canal.

SURGERY.

ACUTE GONORRHŒAL CYSTITIS.

Dr. Wickham recommends oil of sandalwood in acute cystitis of blennorrhœal origin, giving sixteen capsules in the twenty-four hours, each containing about six drops (forty ctgr.) of the fluid. This also has a very beneficial action on hæmaturia. Other balsamics have been found only to irritate and aggravate the symptoms in gonorrhœal cystitis. The action upon the mucous membrane of the stomach is a stimulating one, which permits of suitable diet. Horteloup is given credit for the method, which usually renders instillations of nitrate of silver uncalled for.—*Union Médicale*, No. 145, 1891.

DISEASE OF THE BRAIN FOLLOWING A SIMPLE NASAL OPERATION.

The *Journal of Laryngology, Rhinology, and Otology* gives an abstract of an account of an unfortunate accident described by Wagner in the *Münchener medicinische Wochenschrift.* The author performed a galvano-cauterization of the left turbinated body in a patient twenty years of age, on account of headache. There was no special pain and there was no bleeding. The next day the patient had a severe headache, and on the third day there was hæmorrhage from both nasal cavities. This was treated first with ice water, then by tamponing the anterior and posterior nares. In the evening the patient became feverish, and Cheyne-Stokes respiration appeared. The tampons were removed, but the temperature did not fall and the symptoms of a severe affection of the brain appeared. Seven days later death occurred. A post-mortem examination was not allowed. The author concludes that the bleeding could not have been the direct consequence of the operation, because it followed some days afterward, and because parts bled which had not been operated on. He believes that thrombosis of a sinus occurred, which disturbed the circulation in the nose. In some other published case operative treatment of the middle turbinated body was followed by meningeal disease.

SUCCESSFUL TREPHINING FOR BASAL HÆMORRHAGE.

Smart (*British Medical Journal*, No. 1614, p. 1204) has reported the case of a woman, forty-three years old, in which, following a blow upon the right parietal bone, the face became drawn to the right. There was no

ptosis, no ocular deviation; the pupils were of moderate size, nearly equal, and they re acted fairly well to light; but there was left lateral hemianopsia. Motility and sensibility were impaired upon the left side of the body. Coma, with Cheyne-Stokes respiration, developing, two trephine openings were made, one at the seat of injury, the other a little anteriorly and inferiorly. There was free hæmorrhage from the membranes, but no cause for the symptoms was found within reach of the director or finger. By exclusion, the original diagnosis of a right basal lesion appeared to be confirmed. At once, when the dura was incised, the breathing improved, the relief of the pressure and tension being indicated by the occurrence of cerebral hernia. Subsequent improvement was progressive, the hemiplegic symptoms in some degree, however, persisting. A year after the accident there had been no relapse.

OPERATIVE TREATMENT OF HIP DISEASE.

Ferria (*Centralbl f. Chir.*, No. 6, 1892) describes a method of treating tuberculous disease of the hip which has recently been practised by Caponotto, of Turin, with good results. In the treatment of tuberculosis of this joint by injections of iodoform, the conditions are not so favorable as in disease of some other joints, particularly the knee and wrist. It is not always easy to puncture the hip, and the anatomical conditions of this joint prevent sufficient diffusion of the injected fluid. In order to afford free access of the antituberculous agent to all parts of the diseased hip, Caponotto opens the joint and removes part of the head of the femur. This is done by making an incision about three inches in length, carried from the top of the great trochanter towards the postero-inferior spine of the ilium, and by cutting through the muscles and the capsule on to the head of the femur, about two-thirds of which he then removes with hammer and chisel, whether the bone be diseased or healthy. Sufficient space is thus established between the opposed bones of the joint to permit of removal of diseased synovial membrane, and also of any sequestra or tuberculous deposits in osseous structure, and of subsequent distension of the whole of the diseased articular cavity by injected fluid. After this cavity has been filled with freshly prepared iodoform emulsion, the soft parts are brought together by sutures, and the limb is placed in a good position, though not, unless in very exceptional cases, extended by weights.

SUCCESSFUL TREATMENT OF SUPPURATIVE PHLEBITIS OF THE INTERNAL JUGULAR VEIN AND THE LATERAL SINUS.

Parker (*Liverpool Medico-Chirurgical Journal*, No. 22, p. 44) has recorded the case of a man, twenty-five years of age, who for eleven years following an injury in the region of the left ear, presented symptoms of suppurative otitis media, with perforation of the tympanic membrane. Symptoms of suppurative phlebitis of the lateral sinus and internal jugular vein, with double optic neuritis, developing, an incision was made in the mastoid and intra-auricular regions, and the mastoid process was opened. A clot was found in the facial and jugular veins, extending into the lateral sinus, which was occupied by greenish purulent lymph. Ligatures were applied to the veins on either side of the thrombi, and the intervening portions excised. The lateral sinus was partially scraped. Hæmorrhage was controlled by a plug of antiseptic wax. The symptoms disappeared for two days after the operation; then then the temperature rose to 103°. The wax plug, with some accumulated pus, was removed from the sinus, and the mastoid cells were irrigated. For nearly a week the temperature continued to oscillate between high figures, but finally subsided, the case ultimately progressing to a favorable termination.

A CASE OF FOREIGN BODY IN THE AIR PASSAGES.

Elmer C. R., now æt. fourteen, while tacking up a lambrequin, drew one of several large brass-headed tacks which he was holding in the mouth into the trachea and into the left bronchus, as near as could be determined by external location, about one inch below the bifurcation. The patient was first seen by Dr. Dubois, who found him suffering from spasm of the glottis, dyspnœa, cyanosis, incessant coughing, and a frothy, slightly blood-tinged expectoration. After a few days the irritation passed away and the patient returned to normal health, and the accident was soon forgotten. One year later, and about six months ago, the patient first came to my personal notice. At this time the boy appeared robust and healthy, with, however, the presence of a slight irritative cough. Inspection showed the chest symmetrically developed. Auscultation gave a diminished vesicular murmur over the region of the middle lobe of left lung. Bronchial respiration somewhat marked. Per-

cussion gave dulness and pain over an area two inches in diameter and an inch and-a-half to the left of the median line of the sternum and over the vicinity of the bifurcation of the left bronchus. I gave it as my opinion that the foreign body, whatever it might be, was located in the region outlined above, and the best treatment would be to be conservative and await developments. Aside from the constant dry cough, the patient felt no inconvenience until the morning of August 3d, last, when I was called to see the patient, suffering from violent attack of coughing, accompanied by quite profuse purulent expectoration. During one of these fits of coughing he expectorated the tack that had passed into the bronchus eighteen months before. At this writing the irritation and cough have subsided, and while the respiratory murmur is no quite clear, yet the patient is on the road to recovery. The tack was inclosed in a dark, hard grumous substance, and had probably become encysted, and, in turn, by a suppurative process, had been liberated and expelled by the act of coughing. —*Dr. Wessinger, N. Y. Med. Jour.*

OBSTETRICS.

CHLOROFORM IN OBSTETRICS.

Dr. J. F. Baldwin, of Columbus, Ohio, in a paper read before the Ohio State Medical Society, entered a plea for the more frequent use of chloroform in obstetrics.

His obstetrical triad is as follows:

During the first stage of labor, morphia.

During the second stage of labor, chloroform.

During the third stage of labor, nothing.

Summary.—Chloroform relieves pain.

It shortens labor, usually.

It prevents shock.

Prevents nervous and physical exhaustion.

It reduces the liability to rupture of cervix and perineum.

It does not conduce in any material degree to post-partum hæmorrhage.

It does not affect the fetus.

It is absolutely safe when properly administered.

Contraindications.—1. Such conditions of labor as lead the obstetrician to believe that he may, at some supreme moment, require all the woman's voluntary efforts to assist him. Such conditions are very rare. 2. Fatty degeneration of the heart; though, if we accept the conclusions of the Hyderabad Commission, even this may not be a contra-indication; and the disease is practically never diagnosed except post-mortem.

AMAUROSIS IN THE ALBUMINURIA OF PREGNANCY.

Terrier (*Nouvelles Arch. d'Obstét. et de Gynéc.*, Supplement, September, 1891, p. 385) give brief notes of a case of this kind. The patient was eight months pregnant. Albuminuria set in, and the vision became seriously disturbed. The secretion of urine was greatly diminished, and the general condition was very unfavorable. Twenty ounces of blood were abstracted, and blisters applied to the nape and temples. Compound jalap powder, acetate of potash, and digitalis were administered; the patient was kept on milk diet. On the third day the secretion of urine increased, and the albumen disappeared, but it appears that the patient could not see to read until the sixteenth. Spontaneous labor took place at eight months and a-half. The patient then recovered completely. In this case, even when the symptoms were at their worst, it was not considered advisable to induce premature labor.—*Brit. Med. Jour.*

CUTANEOUS EMPHYSEMA DURING LABOR.

Greslou (*Bull. de la Soc. Obstét. et Gynéc. de Paris*, July, 1891) attended last March, a primipara, aged 24, free from any history of pulmonary disease. The presentation was right posterior occipital, and after a rather long labor the patient was delivered of a male child weighing nearly nine pounds. During the period of expulsion, during a long-sustained effort, the patient felt a crackling sensation in the right cheek, followed by swelling. During the succeeding pains the emphysema visibly increased. It caused great swelling on both sides of the face, but only involved the neck to a trifling extent. The emphysema lasted for two days, little altered, and was accompanied by a cough and slight dyspnœa. Then it rapidly diminished, and disappeared entirely at the end of five or six days. Treatment had been entirely expectant. Greslou notes that Depaul, De-Soyre, and Tarnier have described cases of puerperal emphysema. The complication is rare. It necessarily arises from a rupture of the respiratory tract at some point. If the lies in the larynx or trachea, the escape of air is usually confined to the face and neck, and is not dangerous save in those rare cases where it extends to the trunk. When, however, it is a pulmonary vesicle that has yielded, the complication becomes very serious. The air may escape into the connective tissue of the neck, but it may also fill the intervesicular, interlobar, and subpleural con-

nective tissue, and gravely embarrass the lungs and heart. This accident occurred in a case recorded by Depaul. The forceps was used directly the emphysema was detected, but the patient's condition grew worse, and she died forty-six hours after delivery. In mild cases, where the swelling is limited to the face and the symptom only develops towards the end of the expulsive stage, the forceps is hardly needed, but if there be marked emphysema at any stage the labor must be hastened. After delivery the emphysema usually disappears of itself. Should it invade the trunk and interfere with respiration, a few punctures may be made in the skin in order to allow of the escape of the effused air.—*Brit. Med. Jour.*

PUERPERAL INVERSION OF THE UTERUS.

Puerperal inversion of the uterus may be called immediate when it occurs at the moment of delivery, secondary when it takes place afterward, and chronic when it continues longer than the puerperal condition in which it originated. Statistics show that immediate inversion, though a very rare affection, is more frequent in primiparæ than in multiparæ. It is produced by two pathogenic agents: inertia of the uterus, and pressure from above downward. Adherent placenta is a frequent complication. As soon as the inversion takes place the placenta must be removed, if it has not already been taken away, and efforts made to reduce the tumor. The body of the uterus must be pushed back in such a way that the parts return in a reverse order to that in which they descended, the highest parts being first replaced. The operation may be compared to taxis, although it essentially differs from taxis in that the tumor is usually so large that the pedicle cannot be held by one hand, while the other exerts pressure from below upward upon the uterine mass. Place the hand upon the abdominal wall in such a manner as to fix the infundibulum formed by the inverted uterus, and seize the tumor with the other hand, pressing the fundus with the palm and the sides of the uterus with the fingers. By uniform and energetic pressure from below upward the resistant mass may be pushed back through the cervical ring, while the tumor is kept in place by the hand upon the abdominal wall. Instruments should not be used on account of the danger of perforation. If the operation is unsuccessful, we are compelled to choose between amputating the tumor and allowing things to remain as they are, in the hope that the inversion may become chronic. Prognosis in these cases is so grave, and the condition of the patient so unfavorable, that great boldness is required to undertake a radical operation; nevertheless it has been attempted, and followed in one-tenth of the cases by recovery. It is sometimes rendered imperative by gangrene of the inverted mass. Reports show that there is great danger hæmorrhage may follow section of the uterine and utero-ovarian arteries, and a ligature should, therefore, be placed around a part or the whole of the tumor.—*Journal de Médicine,* January 10, 1892.

GYNÆCOLOGY.

ANTIPYRIN TO DRY UP MILK SECRETION.

Guibert (*Archives de Tocolygie,* 1891) found incidentally that the administration of antipyrin, in doses of thirty grains a day, distinctly diminished milk secretion by the second day. He then tested the drug in nineteen cases. In seven cases the women nursed their children for several days, in the remaining cases not at all. Guibert found that in all cases the milk disappeared in several days.—*Univ. Med. Mag.*

PELVIC INFLAMMATION IN WOMEN:—A PATHOLOGICAL STUDY.

At the recent meeting of the Mississippi Valley Medical Association, at St. Louis, Dr. W. W. Potter, of Buffalo, read a paper entitled Pelvic Inflammation in Women:—A Pathological Study.

The author affirms that pelvic inflammations and their residues constitute about one-third of the diseases the gynæcologist treated, hence the importance of frequent discussions of all moot questions relating to the subject. He briefly reviewed the anatomical relations of the pelvic organs, calling attention to their enormous blood and nerve supply which became both their weakness and their strength. He contrasted the pathology of Bennet (1843) with that of Emmet (1873) and the latter with the teachings of Price, Tait, Hegur and McMurtry of the present age. He referred to the pathological studies of Bernutz and Goupil of thirty years ago, and affirmed that the observations of the present had served to confirm the correctness of those pioneers.

He next asserted that the pathology of to-day had been established by operative surgery which had shown that pelvic inflamma-

tion begins in the tubes or ovaries, and extends to adjacent structures through absorption or by contiguity; that it almost never begins in the cellular tissue, but may be carried there through the tubes and ovaries by infections either specific, puerperal or traumatic. He affirmed that the inflammation was, in most cases, a peritonitis, intra-pelvic or local in character, and not a cellutitis, that para- and peri-metritis were misleading and confusing terms, hence should be dropped, and that the so-called pelvic abscess was a sequence of salpingitis, ovaritis or peritonitis, not a primitive accumulation in the areolar tissue itself.

The tentative management in these cases, rest, counter-irritation, hot sitz baths, vaginal douches and attention to the digestive organs and general health resulted in only temporary improvement, or in cure in a very small percentage. Those reported cured were generally, if the history could be known, subject to repeated relapses and a frequent recurring pelvic peritonitis usually indicated leaky tubes. Electricity, too, had disappointed its most sanguine advocates and need not be considered.

In conclusion, he asserted that if these views be accepted the logical deduction was to watch the early manifestations of the disease carefully, that competent surgical skill be invoked before the damage to important structures became too great to justify the expectation of successful operation.

OBSERVATIONS IN REFERENCE TO THE USE OF ICHTHYOL IN FEMALE DISEASES.

Observations made by Oberth (*Der Frauenarzt, Hft.*, 19, 1891) do not agree with the excellent results reported by Freund. Oberth reports forty-two cases treated with ichthyol. Of these thirty-five were cases of chronic inflammatory swelling of the appendages, and four parametic exudations. His conclusions were that ichthyol does not have a specific effect upon the inflammations about the uterus, nor does it cause resorption of the products of inflammation. He did observe, however, that it quickly diminished the amount of pain. His favorite manner of using the drug is as a five to ten per cent. ichthyol-glycerine on tampons.

TONIC.

℞ Tinct. nucis vomicæ.....gtt. j.
Acid hydrochloric. dilut.....gtt. ij.
Extract. cascaræ fluid .....gtt ij.
Tinct. gentianæ comp.....gtt. v.
Aquæ .....ad f 5 j.
M. To be given three times a day.

PÆDIATRICS.

ICTERUS IN THE NEW-BORN.

From a pathogenic point of view, two forms of this disease must be distinguished, the acute and the chronic. Cuapf (*Rev. Mens. des Mal. de l'Enf.*, October, 1891,) basing his opinion upon his own observations and also upon the investigations of Silbermann, Naunyn, Minkowsky and Affanassiew, the author rejects the theory of a purely hæmatogenous origin for acute icterus, and believes that in all cases there is some disturbance in the liver itself. The new conditions of vitality, which are created by the establishment of respiration, the changes which take place in the circulation, etc., cause a decided change in the condition of the corpuscles, an excess of pigment in the liver, and then biliary stasis and resorption. With reference to chronic icterus, the researches of Gubler, Trousseau, Schüppel, and the author show that it is sometimes due to congenital faults in the formation of the bile ducts, and that it may also be due to acquired lesions of the hepatic tissue and biliary passages. Such lesions are very frequently the result of syphilitic inheritance.

EXALGIN IN CHOREA.

Löwenthal (*Berl. klin. Woch.*, February 1st, 1892) has treated thirty-five cases of chorea with exalgin, the single dose being 0.2 g., and the daily amount not exceeding 1 g. In some the attack was slight, in others severe; the former recovered quickly, but the latter required a longer time. A good number of the cases came under treatment during the first two or three days of the attack, and they mostly recovered in eight days, while others coming in the second week were ill for five to six weeks. In a few cases the disease had already lasted for some months. The smallest total amount of exalgin used was 2.4 g., the largest 112 g. The drug may thus be continued for months in doses of 0.2 g. It was particularly useful when there was much mental excitement. Among unpleasant effects, nausea was noted once, vomiting four times, and headache twice. Owing to giddinesss, it had to be giving up once and arsenic substituted. The chorea then became worse, and the exalgin was again tried with good effect. Jaundice occurred three times. The treatment with exalgin was then omitted and resumed in fourteen days. This is the first time jaundice has been noted after exalgin. In the very severe case of a girl, aged 8, there was

cyanosis of the lips after twenty-six doses. Arsenic was then given, and exalgin resumed in fourteen days without any return of the cyanosis. Exalgin was beneficial in the majority of the cases, but a specific action cannot be attributed to it.—*Brit. Med. Jour.*

THE CEREBRAL ATROPHIES OF CHILDHOOD.

From a review of the clinical types of cerebral atrophy in childhood, of the pathological conditions producing these types, and of the results of surgical treatment by craniectomy, the following conclusions may be drawn: (1) Hemiplegia, sensory defects and imbecility, occurring with or without epilepsy in children, are chronic diseases, incurable by medical treatment. Any means which may be legitmately used to save the individual from a life of invalidism, and to take the burden of care from the family, is to be employed. (2) The pathological conditions producing these symptoms may be either gross defects and atrophies of the brain or an arrest of development in the cerebral cells, without any change apparent to the naked eye. (3) It is at present impossible to determine absolutely the pathological condition present in any given case without an exploratory operation. (4) Such operations are not without danger, but if caution is used in opening the dura, and if the operation is made as short as possible, the dangers are avoided. (5) When manifest atrophies are present the operation will produce no result. When the condition is one of arrested development of cerebral tissue, it may prove of service. When clots, cysts, or tumors are found and removed the chance of recovery is increased. When the skull is markedly microcephalic from early union of the sutures, the increased space given to the brain by the operation seems to stimulate its growth and development. (6) Epileptic attacks are often reduced in frequency and modified in character by craniectomy. When the opening of the skull remains covered only by the soft tissues, it it appears to act as a safety-valve, allowing changes in the intracranial contents to occur without producing pressure on the brain. (7) While hemiplegia, aphasia, athetosis, and sensory defects have been relieved by the operation, it is as yet impossible to predict to what extent imbecility may be relieved. (8) Reports of cases should be made in full, and not within six months of the time of operation, as conclusions connot be trustworthy unless reached by long observation.—*Medical Record*, January 23, 1892.

NODOSE RHEUMATISM IN CHILDREN.

Perret and Diamantberger (*Rev. mens. des Mal. de l'Enfance*, 1891) relate a case of this disease in a girl ten years old. The disease began with pains in the knees and hands when the child was seven years old. Then it attacked the great toe, the radio-carpal and metatarsal articulations. There was also swelling around the three lower cervical vertebræ. Peculiar characteristics were painful paroxysms, with contractures of the muscles contiguous to the diseased joints, and a mitral insufficiency murmur. Nodose rheumatism in children should be distinguished from the same disease in adults by the following peculiarities: many joints are involved in an early period of the disease; there is less centripetal tendency in the evolution of the lesions, the large joints being frequently involved before the fingers, and the exacerbations are of frequent occurrence. During the chronic period deformities are less frequent than with adults, and there is less atrophy. Complications are less frequent; there are no disorders of sensibility, no dystrophy of the nails, no tuberculosis, and rarely any cardiopathies. As to the evolution of the disease, subacuteness is more noticeable at the beginning. The chronic state having been established, there may be improvement and even cure. The ordinarary causes are poverty and dampness, but heredity has no influence. Diamantberger recognizes an affinity between this disease and hysteria, Basedow's epilepsy, idiocy, myxœdema, acromegalia, and Paget's bone disease.

THE VAPOR OF NAPHTHALIN IN THE TREATMENT OF WHOOPING-COUGH.

As a result of considerable successful experience, Chavernac (*Bullettn Gin. de Thèrap.*, 40, liv., 1891, p. 337) recommends fumigation by means of naphthalin in the treatment of whooping-cough. About half an ounce of the drug is, on one or more nights, made to burn in a suitable vessel in the sick room, the windows and doors being tightly closed. The cough at once moderates, the dyspnœa and other symptoms are favorably influenced, and the attack is soon brought to an end. Complications may contra-indicate the employment of the treatment. Thus, individuals suffering with pulmonary tuberculosis cannot bear the treatment.

Green boughs of the eucalyptus tree are recommended to be hung in the room of scarlet fever patients.

HYGIENE.

STEAM AS AN AGENT IN CAUSING THE SPREAD OF DIPHTHERIA.

In a discussion on diphtheria, published in the *British Medical Journal* for September 19, 1891, Dr. Russell cited several instances in which steam had seemed to be an active factor in the propagation of the disease. Hot water and steam from a brewery were introduced into some old cesspools and evidently waked into activity germs which, if undisturbed would have remained dormant. An epidemic of diphtheria soon developed in the vicinity, and was not checked until the steam was turned into other channels, when it quickly ceased. If, as we now believe, the bacillus of diphtheria develops with special rapidity in the presence of warmth and moisture and absence of light, it is not unreasonable to suppose that the introduction of hot water or steam into cesspools or sewers may be a most dangerous procedure. The maintaining of a considerable degree of heat in sewers can certainly not be wise from a hygienic point of view. Yet this condition prevails quite largely in New York, where sewers and water pipes are in many places kept at a continuous high temperature by the close proximity of the pipes of the steam-heating companies. No more favorable medium for the culture of micro-organisms could be found than warm sewage. Given an imperfect trap and a vulnerable mucous membrane, and an attack of diphtheria is almost assured.

DISINFECTION OF DENTAL INSTRUMENTS.

There is no department in surgery, writes Dr. Miller, of Berlin, in which the demand for antiseptic procedure is more urgent than in dentistry, for the reason that all the operations are performed upon septic or infected tissues and there are no means of rendering the territory to be operated upon aseptic except by the use of antiseptics of the highest character. The necessity of absolute cleanliness on the part of the dentist, of his hands as well as his instruments, diapers, drinking glasses, rubber dam, in short, everything which comes in contact with the patient's mouth, is universally recognized, and yet it is not difficult to find persons engaged in the practice of dentistry who neglect this matter to an extent that is revolting to the taste and dangerous to the health.

In regard to the possibility of transmission of disease, such as pyemia or syphilis, by dental instruments, there have been so many cases recorded in dental and medical journals that the matter should be familiar to every practitioner of dentistry. With reference to diapers, Dr. Miller found that boiling in water for ten minutes completely sterilized them, and no development of bacteria could be produced in agar-agar. The rubber dam should be soaked in a 5 per cent. solution of carbolic acid for at least half an hour, or boiled for a few minutes, but preferably a new piece should be used for each case. The ideal antiseptic for instruments is a liquid which acts immediately upon bacteria without in any way injuring the instruments themselves. There is a vast difference between sterilizing liquids and sterilizing solid bodies, and an antiseptic which sterilizes a drop of water almost instaneously may require a quarter of an hour to sterilize a solid body, particularly when it is coated with a layer of dried albuminous material, as dental instruments are liable to be. The length of time necessary to sterilize a body by a chemical agent depends greatly upon the character of the body, as well as upon the character of the matter with which it is coated. Porous bodies, as may be readily understood, are more difficult to sterilize than non-porous ones; also the drier and more insoluble the material with which the body is coated, and the more liable it is to form inert compounds with the antiseptic, the more difficult it will be to sterilize. It is consequently, above all things, desirable to employ the antiseptic in a form in which the infectious matter is soluble, and this in the vast majority of cases is in an aqueous solution. Dr. Miller has performed about a thousand experiments, and gives in a tabular form the results obtained with the most noticeable agents. Of carbolic acid, he says the impression exists amongst a great many that it is but necessary to dip the instrument in the solution for a fraction of a minute in order to render it completely sterile, but thorough sterilization with a 5 per cent. solution cannot be counted upon with moderate certainty in less than an hour, and a large burr, such as is used with the dental engine, after two hours' exposure was still found to contain living germs. Trichlorphenol gave slightly better results. Bichloride of mercury in a 5 per cent. aqueous solution was found to be by far the most prompt in its action of all the substances tested, but its powerful action upon the steel interferes very seriously with its constant use for sterilizing instruments made of this material. Peroxide of hydrogen came next to carbolic acid, but

it was considerably inferior to it. The essential oils utterly failed to produce the desired action. Boiling water, especially when a 2 per cent. solution of carbonate of soda is added, is, in Dr. Miller's opinion far superior to all other means of sterilizing; it will accomplish in two minutes as much as the chemical agents ordinarily used will in half an hour.—*Lancet.*

ADMINISTRATION OF ALCOHOLIC BEVERAGES TO CHILDREN.

The *Journal de la Santé* calls attention to the habit many persons have of giving infants and children alcoholic beverages like whisky, brandy or beer to induce sleep. This practice cannot be too strongly condemned, for aside from the injurious effects of alcoholic drinks upon the child's system, the restlessness can be more effectually controlled by a tepid or warm bath given at bedtime, especially during the period of dentition. When young children are delicate, a few drops of brandy given occasionally in milk, may have a good effect, if the child suffers from digestive trouble. It should be remembered that 15 or 20 drops are ample for a baby and a larger quantity should not be administered without the physician's advice.

TEMPERANCE AND THE LONGEVITY OF CLERGYMEN.

It is satisfactory to know, on the authority of Dr. Drysdale, that the mortality of the clergy of the Established Church of England has fallen greatly since the spread of the temperance movement among them. Whereas between 1861 and 1871 the mortality of the clergy between the ages of twenty-five and forty-five was 5.96 per 1,000, it fell between 1880–82 to 4.64 per 1,000. The question may be raised whether this apparent lessened mortality among the clergymen may not be evidence of the universal fall in the death-rate during recent years, of which the apostles of sanitation claim the credit.—*Hospital Gazette.*

CLEANSING OF THE HANDS AFTER THE USE OF CARBOLIC ACID OR CORROSIVE SUBLIMATE.

Carbolic acid is removed from the hands by bathing them for a sufficient time in alcohol and then anointing them with lanolin. after the use of corrosive sublimate solution the hands should be bathed in a solution of common salt 1 to 50, then washed with soap and water, and finally rubbed with lanolin.

MEDICAL CHEMISTRY.

A SUBSTITUTE FOR GUM ARABIC.

The *Mühlen und Maschinen-Industrie Zeitung* is authority for the statement that a German patent has been issued for a process of manufacture of a substance to take the place of gum arabic. Wheat bran is the substance treated, the process being described as follows: By first washing with water all adhering starch is removed from the bran, whereupon it is boiled with an ammoniated salt solution in order to remove the proteins. After expressing and lixiviating with clear water, there remains a mass of cellular tissue containing metarabin. This cellular tissue is boiled, under pressure, with milk of lime or a one per cent. solution of potassa, then expressed, the liquid neutralized and finally concentrated by evaporation. The resulting mucilage is claimed to possess strongly adhesive properties.

HYDRAZOIC ACID.

Professor Curtius, in the *Berichte der Chemischen Geselschaft*, reports the results of his further examination of the compound N_3C, to which the names of hydrazoic, nitrohydric, and imidazoic acids have been applied by different investigators. Professor Curtius describes his methods of obtaining some of the salts of the acid, upon which investigation can be carried out with less danger than with the material itself. The silver salt N_3Ag may be obtained in colorless crystals by evaporating an ammoniacal solution. It is violently explosive. The mercurious salt N_3Hg is crystalline, and acquires a yellow color on exposure to light. It is less explosive than the silver salt, and on the addition of ammonia is converted into a black, insoluble substance. The lead salt N_6Pb forms colorless crystals, closely resembling lead chloride. It is insoluble in ammonia, and very sparingly soluble in boiling water, and when slightly warmed exploding with great violence. The sodium salt N_3Na is also crystalline. It is feebly alkaline, very soluble in water, insoluble in alcohol and in ether. It does not explode when struck, but only when heated. The ammonium salt N_4H_4 is extremely explosive, and very volatile, but can be crystallized from a solution in boiling alcohol. On the addition of ether to the alcoholic solution, the salt is precipitated in the form of a snow-white crystalline powder. A water solution evaporated in vacuo yields large transparent prisms, which become dull on exposure to the air.

TO DETECT SUGAR IN URINE.

Flint (*Medical News*) describes a simple apparatus for detecting the presence of sugar in the urine, when the results of Fehling's tests are uncertain. A small straight bottle or a small test-tube is fitted with a cork, through which is passed a small tube that reaches nearly to the bottom. The glass tube is bent so that the apparatus will hang over an ordinary test-tube or other convenient vessel. The bottle is completely filled with urine, with which a piece of Fleischmann's yeast, about the size of a pea, has been thoroughly mixed. In putting in the cork it is necessary to be careful to exclude every bubble of air. If the apparatus be kept for a half hour at a temperature of from 80° to 90° F., a bubble of gas will appear if sugar be present in the smallest quantity. The apparatus may be placed in the sun or near a heater, but the temperature should not be higher than 100°.

NEW THERMOMETRIC SCALE.

F. Salmon (*Zeit. f. angew. Chem.*) proposes a scale which has an absolute relation to zero, so that its readings directly indicate the volumes of gases at various temperatures. The starting point is 273° C.; from this to the freezing point of water the scale is divided into 100 equal parts, so that 0° C. corresponds to 100 of the new scale. From this to 273° C. the scale is again divided into 100 equal parts, 273° C. being 200, the same proportion of division being continued as far as desired. Each degree of the scale is therefore equal to 2.73° C. and 1° to 0.3665° of the new scale; the boiling point of water lies at 136.6°, The use of the new scale is seen from the following examples: One cubic metre of gas at 0° C. or 100° absolute temperature would measure at the boiling point of water (136.6°) 1,366 liters. At 200° C. or 173.2 absolute temperature, it would have a volume of 1,732 liters. G. Lunge recommends this scale as forming the solution of a little difficulty which is felt in gas analysis.

ESTIMATION OF TOTAL ALKALOIDS IN QUININE BARKS.

The following method has been recommended by Herr W. Haubensak as preferable to that in general use; the chief difference is that sulphuric acid is used to take up the alkaloids from the ether-alcohol ammonia solution, by which means they are obtained free from resinous matters and wax: Twenty grams of the bark is very finely powdered and put into a 500 c.cm. flask with 10 c.cm. of 10 per cent. ammonia and 20 c.cm. of 94 per cent. alcohol; 170 c.cm. of pure ether is added, and the whole shaken occasionally during two or three hours. Pour off 100 c.cm. of the clear extract into a separator, and shake with 50 c.cm. of water and a slight excess of sulphuric acid. Allow the fluids to separate, and run off the lower acid solution; warm, to expel the dissolved ether, and return to the separator; add 30 c.cm. of chloroform, liberate the alkaloids with a few drops of soda, shake well, run off the chloroform solution on to a tarred dish. Allow to dry spontaneously in the air, and then at 100 degrees, and finally weigh. The process occupies four or five hours, and is entirely satisfactory.

NEWS AND MISCELLANY.

THE PAN-AMERICAN MEDICAL CONGRESS.

The Committee on Peamanent Organization met at St. Louis, October 14, 15, and 16, 1891, and adopted a series of General Regulations for the permanent organization of the Pan-American Medical Congress, and a series of special regulations for the government of the first meeting, and recommended that the Incorporators adopt both series of regulations as the organic law of the Congress.

Pursuant to such Regulations the following general officers were elected:

William Pepper, M.D., LL.D., Philadelphia, Pa., President; Abraham M. Owen, A.M., M.D., Evansville, Ind., Treasurer; Charles A. L. Reed, M.D., Cincinnati, Ohio, Secretary General.

International Executive Committee:—Argentine, Dr. Pedro Lagleyze; Bolivia, Emilio de Tomassi; Brazil, Dr. Carlos Costa; British North America, Dr. James F. W. Ross; British West Indies, Dr. Jas. A DeWolf; Chili, Dr.Moises Amaral; Columbia, P. M. Ibañez; Costa Rica, Dr. D. Nuñez; Ecuador, Dr. Ricardo Cucalon; Guatemala, Dr. José Monteris; Haiti, Dr. D. Lamothe; Hawaii, ———; Spanish Honduras, Dr. George Bernhardt; Mexico, Dr. Tomas Noriéga; Nicaragua, Dr. Juan I. Urtecho; Paraguay, ———; Peru, Dr. José Cassamira Ulloa; Salvador, Dr. David J. Guzman; Santa Domingo, ———; Spanish West Indies, Dr. Juan Santos Fernandez; United States, Dr. A; Vander Veer; Uraguay, Dr. Jacinto De Leon; Venezuela, Dr. Elias Roderiguez; Danish, Dutch, and French West Indies, ———.

The Auxiliary Committee nominated by the various members of the Committee on Permanent Organism each for his own state, and already commissioned by the Chairman, was affirmed.

The election of officers of sections was begun, but time would not permit of the completion of the list which was referred to a special committee with power to act. It has been deemed inexpedient to publish the list until it is completed, which can hardly be accomplished before the meeting of the Committee on Permanent Organization at Detroit in June; but the organization of particular sections will be announced through the medical press as rapidly as officers are elected by the special committee.

In accordance with the wish of the Committee on Permanent Organization as expressed in Special Regulation No. 4, Drs. I. N. Love, A. B. Richardson, L. S. McMurtry, R. B. Hall, T. V. Fitzpatrick, and Charles A. L. Reed met in Cincinnati and signed the legal form of application for Articles of Incorporation of the Pan-American Medical Congress, which Articles of Incorporation were duly issued by the Secretary of the State of Ohio, under date of March 15, A.D. 1892.

At a meeting of the Incorporators held March 16, 1892, the Regulations, general and special, recommended by the Committee on Permanent Organization were formally adopted as the organic law of the Pan-American Medical Congress in accordance with the Laws of Ohio, and all elections had by the Committee on Permanent Organization, in accordance with such regulations were confirmed and made a part of the laws of the Congress.

Pursuant to the Laws of Ohio and the Regulations adopted as above, and in accordance with nominations by the Committee on Permanent Organization, the Incorporators elected fifteen Trustees as follows:

Dr. W. T, Briggs, Tenn.; Dr. Geo. F. Shrady, N. Y.; Dr. P. O. Hooper, Ark.; Dr. S. S. Adams, D. C.; Dr. H. O. Marcy, Mass.; Dr. J. F. Kennedy, Iowa; Dr. H. D. Holton, Vt.; Dr. L. S. McMurtry, Ky.; Dr. N. S. Davis, Ills.; Dr. Levi Cooper Lane, Calif.; Dr. I. N. Love, Mo.; Dr. Hunter McGuire, Va.; Dr. J. C. Culbertson, Ill.; Dr. A. Walter Suiter, N. Y.; Dr. C. H. Mastin, Ala.

Drs. L. S. McMurtry (Ky.), I. N. Love (Mo.), and W. W. Potter (N. Y.), were designated to act as members of the Executive Committee.

The organization of the Congress is complete in British North America, the British West Indies, the Spanish West Indies, Gautemala, Nicaragua, United States of Colombia, Brazil, Uruguay, Venezuela, and the Argentine. It is confidently expected that the nominations from the remaining countries will be in by June.

It is expected to announce the completed organization of the Congress, its sections and auxillary committees, domestic and foreign, by July 1, 1892.

On behalf of the Committee on Permanent Organization.

Charles A. L. Reed, Chairman.
J. W. Carhart, Secretary.

DR. D. HAYES AGNEW.

At a meeting of the Medical Faculty of the University of Pennsylvania held Thursday March 24th, the following minute was adopted:

The Faculty of the Medical Department of the University of Pennsylvania, desires to place upon record its profound grief at the irreparable loss sustained in the death of Dr. D. Hayes Agnew, and to express its thorough appreciation of the nobility of his personal character and the enduring excellence of his professional achievements.

Dr. Agnew was for years a regular attendant at the meetings of this Faculty, and his wise counsel, his unswerving advocacy of every progressive movement and of all that tended to raise the standard of teaching and of the profession, have left their indelible mark on the history of its proceedings.

As a didactic lecturer, he was unsurpassed. Without apparent effort and with a skill born of thorough knowledge and perfect mastery of his theme, each subject was presented to the student so clearly, simply, and directly, that it remained a part of his medical knowledge.

As a clinical lecturer, his enormous experience and his diagnostic and operative skill made him pre-eminent. The skill, which amounted to genius, was the foundation of his scientific greatness, and often enabled him at a glance to detect conditions which had eluded the search of others. No clinical observation even in times long past, escaped his memory, and his experience, almost without exception, furnished a parallel to the rarest and most obscure cases. He had, in addition, the faculty of elucidating in a few words the method by which he reached his conclusions, and this unusual combination of qualities gave him his unquestioned position as the leading teacher and practitioner in surgery in this country. His colleagues can bear

witness to his warm friendship, which never failed in time of need; to his genuine love for his work and his eager desire to acquire every new fact that might benefit his patients; to his generous support of the feeble, the halting and unfortunate in the profession; to his respect for every honest opinion even if it differed from his own; to his quick and ready sympathy and his tender treatment of all those who claimed either his personal or his professional help. His gentle courtesy and kindly bearing won the love of all with whom he came in contact. To the members of this Faculty, his students of years gone by, his colleagues of yesterday, and always his loving friends, his death comes as a personal bereavement.

Resolved that a copy of this minute be sent to the family of Dr. Agnew, and that it be suitably published.

JAMES TYSON,
March 25th, 1892. Dean.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

The Chair of Obstetrics has become vacant through the resignation of Dr. E. E. Montgomery, who will hereafter devote himself entirely to the Chair of Gynæcology.

A NEW AND POWERFUL LIGHT.

A very intense light, such as is required for photographic or occasionally for medical purposes, may, as is well known, be readily obtained by burning magnesium ribbon, which has, however, the disadvantage of being somewhat expensive. An excellent substitute has been found by a French chemist, M. Villon, in aluminium, which is about a third of the price of magnesium, and which may be utilized in the same manner by burning it in a spirit lamp, or, if a flame of much more intense brilliancy is required, in a coal, gas, or spirit flame supplied with a jet of oxygen. In these it burns without emitting fumes, in which respect it is superior to magnesium. The light given by aluminium has a high actinic power—nearly as high, indeed, as that of magnesium. The most convenient way of obtaining a very intense light, according to M. Villon, is to use a lamp provided with a jet of oxygen at the centre of its flame, into which powdered aluminium mixed with a quarter of its weight of lycopodium and a twentieth of its weight of nitrate of ammonium can be projected by means of a tube furnished with an air-ball. This gives an exceedingly intense light, without smoke. A mixture of aluminium powder with chlorate of potash and sugar can be ignited, giving an intense light by means of gun-cotton, but is somewhat dangerous. Probably the best plan for medical photography, or for laryngoscopic and auroscopic and other demonstrations, would be to burn a ribbon of aluminium in an ordinary spirit lamp. Of course, if oxygen and an oxy-hydrogen, or an oxy-alcoholic, lamp were at hand a much more intense light could be obtained.—*Lancet.*

DR. BROWN SEQUARD AND ISOPATHY.

Drs. Brown-Sequard and d'Arsonval propose a *new* therapy, (*Rev. int. de bib. Med.*) consisting of combating the morbid manifestations of an organ, by injecting the juicy extract of that organ. Thus in cases of myxœdema, of exophthalmic goitre, or after thyroïdectomy, they propose to use the *thyroïdian juice;* in cases of Addison disease, the liquid of suprarenal capsules; in diabetes, the juice of pancreas; in cases of leucocythæmia, the juice of lymphatic glands, of spleen or of marrow of bones; in cases where the muscles are flabby, thin and weak, without any existence of nervous affection, of juice extracted from muscles. The liquids extracted from glands or other organs of mammalians, without sufficient sterilization and filtration, generally always cause death in less than ten days, but rarely by septicæmia, which prove that toxic substances or those liable to become so, are furnished by the principal organs of the system. The juice extracted from sexual glands are the only exceptions and are not dangerous. The method employed by the authors is to prepare a glycerinated solution made of one-tenth of the juice, obtained by maceration of the tissue for about a half hour, adding to it three times its weight of pure officinal glycerine, then macerate for another half an hour, after adding distilled water six times the weight of the tissue juice. Filter and sterilize by CO_2 at 40 atmosphere.

Thus Dr. Onimus, of Monaco, has used, in a case of asystole, the hypodermic injection of cardiac muscle, which made the suffocative attack disappear. Other symptoms, such as, difficulty to walk, breathlessness, general weakness, have been ameliorated by injections of extracts prepared by maceration of pieces of spinal marrow in glycerine. Similar injections have ameliorated a case of labio-glossolaryngeal paralysis, and same results obtained in three other cases of spinal troubles, such as, transverse myelitis, chronic meningitis and ataxia in its early stage.

LITHIA.

EACH DESSERTSPOONFUL CONTAINS:
℞ Salicylate Lith a 10 grains, and Bromide Soda 10 grains.

A REMEDY IN THE TREATMENT OF
RHEUMATISM, GOUTY DIATHESIS, ETC.

Dr. A. Garrod, the well-known English authority on Gout, who was the first physician to introduce the Lithia Salts in the treatment of Gouty Diathesis, states that their action is materially increased by being administered in a *freely diluted form.*

This effervescing salt of Lithia furnishes an easy and elegant way of applying Dr. Garrod's methods.

INGLUVIN

A SPECIFIC FOR VOMITING IN PREGNANCY.

A POWDER:—PRESCRIBED IN THE SAME MANNER, DOSES & COMBINATION AS PEPSIN

In Doses of from 10 to 20 Grains,

AND A POTENT AND RELIABLE REMEDY FOR THE CURE OF

Marasmus, Cholera Infantum, Indigestion, Dyspepsia and Sick Stomach,

caused from debility of that organ. It is superior to the Pepsin preparations, since it acts with more certainty, and effects cures where they fail.

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the *Proportion of Oil* it contains.

3d—In mode of manipulation and thorough incorporation, rendering it *Permanent* and *Palatable,* and of proper consistence, *about that of Rich Cream.*

4th—*In Size of Bottles,* containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

GRIPPAL PNEUMONIAS: I.—GRIPPAL PNEUMONIAS FROM A CLINICAL POINT OF VIEW. II.—ACTION OF THE GRIPPAL POISON. III.—THERAPEUTIC INDICATIONS. IV.—TREATMENT.*

By H. HUCHARD, M. D.,
of Paris, France.

I.—GRIPPAL PNEUMONIAS FROM A CLINICAL POINT OF VIEW.

Gentlemen:—I have told you, based upon microbiological researches, that grippal pneumonias are not different from the fibrinous pneumonias, since in both cases the same pathogenic germ, the pneumococcus, is found. I have likewise said that another microbe, the streptococcus, is frequently met with in all the pneumonias of influenza. Finally, it has been established that grippal infection is the result of microbian associations, and, without taking into consideration the new bacillus of Pfeifer, there have been described in patients suffering from the grippe many pathogenic germs, such as the streptococcus pyogenes, the staphylococcus pyogenes aureus, and the pneumococcus. Undoubtedly, it is to this association of microbes that the troublesome and complex pathology of this peculiar malady is due. Considering the numerous medical opinions which have originated at every new outbreak of the epidemic, I may repeat what an old historian of the 15th century has remarked: "No physician, nor anybody else, has been able to say what the disease is."

Clinical studies have sufficiently revealed to us that influenza is of microbian origin, and as I have already gone over this matter, though in a rapid manner, I deem it of importance now to consider the subject from clinical and therapeutic points of view. In regard to microbicidal medication, this will first claim our attention.

Certainly during the epidemic of the grippe we find fibrinous pneumonias (that is pneumococcic pneumonias, to use the language of to-day) which do not arise directly from the disease in question. Such pneumonias take their regular course, exhibiting well-known symptoms, symptoms which are unnecessary for me to mention. We also have, however, grippal pneumonias which belong essentially to the epidemic affections, (streptococcic pneumonias, if you please) especially pneumonias which clinical studies have made known to us.

You have seen patients presenting all the signs of pulmonary hepatization with more or less dullness over one of the lungs, accompanied with bronchial murmurs, crepitant râles, increased vocal fremitus, a decrease in the bronchophony of the voice and more or less intense dyspnœa. After these physical signs are manifest, fibrinous pneumonia appears under more marked characters, and, nevertheless, there are noticed the following peculiarities: there are no rusty sputa; the expectoration consists of a thin, frothy and scanty fluid, resembling a gummy solution; sometimes the sputa are compact, muco-purulent and absolutely deprived of air. In these instances, bacteriological examination of the sputa has revealed, according to Duponchel, an important peculiarity, that is, the absence of the capsulated diplococci of pneumonia. That is not all. The patient may have pain on the side, but there is no sign of friction which is so characteristic, or he may exhibit some slight and repeated frictional signs similar to those observed in pleurisy. The disease may come on in an insidious manner, so to speak, making itself known only by a feeble pain on the side, a more or less pronounced febrile reaction and by symptoms of dyspnœa. After the eighth day, defervescence takes place, but this is only incomplete and ephemeral. Soon afterwards the fever is re-estab-

*A Clinical Lecture delivered at the "Hôpital Bichat."

lished, at the same time new pneumonic foci make their appearance at various points of the pulmonary parenchyma. Here we have, in a word, a pneumonia coming on by successive steps, in which the thermal curve is absolutely different from that of common pneumonia, the condition resembling more one of broncho-pneumonia.

We have other pneumonias characterized by a rapid march, soon arriving at the stage of hepatization, accompanied with a sanious and abundant expectoration, which are really *galloping* pneumonias (so named, since 1880, in the thesis of my pupil Doussian),* their whole evolution taking place in the period of from forty-eight hours to three days at the least.

We also have bastard pneumonias so-called, which are observed under the form of pulmonary atelectasis, of a subacute and slow progress, without great elevation of temperature, and which can be borne for many weeks without any therapeutic interference. You have active and rapid pulmonary congestions, in which a true hæmoptysis may lead you to suspect tubercular trouble, but in which there is an absence of the bacillus Koch in the bloody expectoration. If in such instances the temperature is not very high, it may at least reach 41° C., as in two cases described by Doussian, both of which recovered. Again, these pulmonary congestions are characterized, from a stethoscopic point of view, by a diminution or total absence of the vesicular murmur. Respiration is quiet, the expectoration resembles a thick, gummy solution, and to establish the diagnosis of *congestion of the lung,* you have no other signs than the dullness, the increase in the thoracic vibrations and the dyspnœic condition of the patient. Still in another class of cases, both lungs become the seat of numerous compact, crepitant râles which convey to the ear the sensation of a small, fine shower, the whole condition presenting an aspect of a mixture of pulmonary congestion and œdema. Deceived by the absence of respiratory murmurs, you may be induced to give a favorable prognosis; but the congestive wave, so to speak, continues; both lungs become affected from the base to the apex, cyanosis makes its appearance on the lips and on the extremities which become also cold, and to your astonishment your patient is carried away by almost acute asphyxia. This mechanical asphyxia, however, is not always produced by the congestive trouble; it may also be the result of a true *massive pneumonia,* as we to-day term it, and as Nonat so well observed during the epidemic of 1837, and in which he described pseudo-membranous concretions obliterating almost completely the lumen of the bronchial tubes.

The asphyxia may have a different origin, not being due simply to mechanical disturbance as the result of pulmonary obstruction from the congestive condition. The patient may have bronchitis with limited pulmonary congestion, accompanied with large crepitant râles, but without a blowing respiration. The tongue may remain moist, the bodily temperature but little affected, and led by these negative signs, you will not give much attention to the gravity of the prognosis. You notice, however, a condition of dyspnœa, a condition at variance with the comparatively stethoscopic phenomena. Soon afterwards, the respiration becomes embarrassed, the expectoration is difficult or ceases altogether, congestion advances quickly, and asphyxia rapidly kills the patient; or else, as is often the case, death takes place through syncope, preceded, for a few hours, by the symptoms of cardiac collapse. Graves, who has observed these cases, says, and not without reason, that patients succumb to "pulmonary paralysis." These pneumonias or congestion of *bronchoplegic* or *cardioplegic* form, as I call them, attack the nervous system and particularly the functional activity of the vagi.

I have gone so far without saying anything to you about meta-pneumonic purulent pleurisies, pulmonary gangrene, bronchitis with purulent expectoration, and other forms of pulmonary congestions, etc. I will endeavor to show that there is no such thing as a grippal pneumonia, but that we have grippal pneumonias. Clinical studies demonstrate this and bacteriology confirms it. We have congestive pneumonias, inflammatory pneumonias, and suppurative pneumonias: those produced by the pneumococci, and those caused by the streptococci. The grippe raises to the highest point the virulence of all micro-organisms, and this explains the frequency and the constant threatenings, so to speak, of infections secondary to this disease. If all fibrinous pneumonias terminate frequently by gray hepatization, this is because the microbes of suppuration co-exist with the pneumococci, and it may be said, therefore, that all suppurative pneumonias are the result of secondary infection.*

*Doussian:—Contribution à l'étude des formes cliniques et du diagnostic de la grippe (Thèse inaug. de Paris, 1880).

*D. Plaguere (Thèse inaugr. de Paris, 1888).

Many are the varieties of these grippal pneumonias. Potain said to me one day, apropos of an extraordinary case of influenza which I brought to his notice "With this grippe one has to re-study his pathology." The same thing may be said in regard to the therapeutic management of the disease.

II.—THE ACTION OF THE GRIPPAL POISON.

Grippal pneumonias do exist, as I have endeavored to show you by clinical study; they have their own individuality, their peculiarities and their special characteristics. But in the midst of the various and complex assemblage of these pneumonias, there is an important fact which has called the attention of clinicians of all countries and at all times, and that is, the nervous asthenia, the profound adynamia. This nervous asthenia precedes or accompanies all the local manifestations of influenza, and may at the same time continue for weeks and even months. There is one thing that you have observed, and which Graves refers to as a pulmonary paralysis, and which I myself attribute to a sort of inertia or paralysis of the vagi nerves.

Such may by explained, on the one hand, by the production of rapid pulmonary congestion and on the other, by phenomena of bronchial paralysis which I have studied under the name of *bronchoplegia* or else *cardioplegia*, a condition that is apt to produce death through a marked asphyxia, or suddenly (although this exceedingly rare) by an unforeseen cardiac syncope. The pneumogastrics of certain grippal patients, as I have observed during the last epidemic, are undoubtedly greatly affected, proved by the fact that the pulse is slowed in many cases, such forming a singular contrast with the elevation of the bodily temperature. One of the historians of the epidemic of 1837, Landau, has remarked that the pulse, ordinarily large and full in this affection, was sometimes small and slow, and except in two cases in which it rose as high as 86, it never passed 72, and most generally it varied from 60 to 68.

Again, during an attack of influenza the arterial pressure is diminished, the elasticity and contractility of the weakened vessels no longer sustain the heart which, deprived at the same time of its normal influences and vascular supply, is the prey of exhaustion; hence, cardiac collapse. There comes, similarly, a peculiar syndrome, a condition which I am in the habit of speaking of as a fœtal rhythm of the cardiac beat, a condition which I have studied under the name of *embryocarditis*, and which I regard as the precursory sign of approaching dissolution.

The grippal poison not only paralyzes the pneumograstric nerves, it not only threatens the contractility of the bronchi and the heart itself, but it also acts upon the medulla oblongata, which explains the production of certain hyperthermias; hyperthermias incompatible, indeed, with the by no means marked intensity of the local lesions, with the Cheyne-Stokes respiration, or with the post-grippal glycosuria and albuminuria which I have observed.

III.—THERAPEUTIC INDICATIONS.

I have often said, and will now repeat, that in pneumonia the disease is in the lungs, but the danger is in the heart. In grippal pneumonia the danger lies chiefly in the nervous system. It is our knowledge of this fact that must lead us to recognize the therapeutic indications.

In all grippal manifestations we ought not to consider this or that diseased organ and direct to that alone our therapeutic measures. For instance, a simple disturbance of the stomach shows itself. It persists after many weeks notwithstanding all treatment. If in that simple gastric derangement, (which is only a point in your diagnosis) you take nothing in consideration but a diseased stomach or else an intestine in which there is a rapid increase of toxines or micro-organisms, then your therapeutic medication is irrational. Behind this affection, although simple in appearance, there is an alteration of the nervous system, an asthenia difficult to overcome and against which you may wrestle without a chance of success. This is true during an epidemic of influenza, when without fever or any local manifestation, the disease is only characterized by this nervous asthenia to which the term *grippal state* may properly be given. It is this asthenia, without any gastric disturbance, that you try to combat when it is free from all complication. You must not forget that derangement of the stomach is only an element superadded to the nervous asthenia.

The same holds good in regard to grippal pneumonias; but here, the intensity of the inflammatory processes is such, that very often all your attention is directed to the lungs, which permits you to see only a diseased organ when, in fact, the whole system is affected. What can you do against a pneumonic process which must have its own precise cyclical evolution? Nothing, or almost nothing. We no longer recommend the expectorants, kermes mineral, antimony, that

is, all those remedies which depress the heart; nor blood-letting which depresses the forces and which is only indicated in special cases, such as peripneumonic congestion or threatening mechanical asphyxia; nor even blisters, which constitute the chief indication, are now ever employed. If you follow such a practice, employing these medicaments and measures in a systematic manner, from routine, you will only make conditions worse, by adding a bad remedy to a bad disease.

In the course of pneumonia or pulmonary congestion, there is a compensatory organ which will be called upon to wrestle constantly against the enormous disturbance of the circulation, and such an organ is the heart. It is that which, from the very beginning of the disease, must be sustained and strengthened in a systematic manner, without waiting for the organ to become weakened in its functional activity and contractility. You must not forget that in influenza the heart is more markedly affected in its nervous mechanism than in its muscular element. This in view, you must not commit the error which I shall presently point out to you. A pneumonia, more or less diffused, is developed. The heart, apparently unaffected during the first few days, becomes accelerated in its action, the systole is vigorous, the pulse has a vibrating character, and owing to these circumstances you are apt to believe in non-cardiac interference. You do not notice that the heart is acting violently in the struggle, and that as a result of this, exhaustion of it will ensue, from which it will never recover; and that this apparent cardiac force is an index, a proximate cause of its weakness. Such order of things have I observed in many cases.

Following this period of excitation, weakness of the organ ensues, and it is only at this time that you think of administering digitalis, when nothing can be done for an organ whose contractility has been enfeebled, and when diuresis cannot be produced owing to the impermeability of the kidneys, this condition appearing at an advanced period of the disease. Digitalis must be prescribed at the very beginning of the pneumonia. It is this method of treatment which I especially recommend, and which has been adopted by other authors, such as Traube, Hirtz, Coblentz, Duclos, Sancerotte, Jurgensen, etc.

To combat the effects of pneumonia, or to prevent them, we must direct our attention to the heart, and this should constitute a principle of therapeutics, to which I have given the name of *compensatory therapeutics*. I will explain myself.

You are in the presence of a serious case of icterus. The symptoms become more and more alaming, the adynamia is profound, and hæmorrhages threaten the life of the patient, when suddenly there appears a marked urinary crisis and a fatal issue is warded off. What is the lesson taught us by a clinical case of this nature? It shows us that such a result has not depended upon the liver, that is, upon the affected organ, but upon the compensatory organ, upon the kidneys that serve to eliminate the morbific elements, the toxines which the hepatic cells, profoundly altered, have not been able to destroy or neutralize. You know very well that in order to have a healthy functional activity of the organism, when a portion of it fails in its action, another must take its part. One of the functions of the liver is to destroy the numerous toxic bodies that go through its structure, while it is the duty, so to speak, of the kidneys to eliminate poisonous materials. Therefore, in diseases of the liver our medication must be directed to the renal organs; in cases of pneumonia the heart is the focus around which we must concentrate all our attentions. In one word, and as one of my oldest resident physicians, Weber, has fitly remarked: "When an organ is affected we must look after the healthy and compensatory organs." You must, therefore, exercise in therapeutics a sort of turning movement; and you know that often a turning movement will lead you to the accomplishment of a brilliant victory.

The indications for the use of digitalis present themselves almost in all cases of fibrinous pneumonias, not only to combat the febrile element, not to act directly upon the pneumonic process, (which is impossible), but to give the heart a kind of reserve power for the expected struggle, and moreover, to enhance diuresis, thus bringing about a depuration of the organism. It is to insure this depuration that we must exercise an influence upon the kidneys and upon the digestive tract to modify fermentation by means of intestinal antisepsis.

Finally, clinical studies show that the nervous system must be sustained and strengthened. The administration of digitalis must be resorted to in all these cases of grippal pneumonia in which the vagi nerves and the medulla are more or less affected, and in order also to avoid auto-intoxication through the inactivity of the eliminative organs. Digitalis must be prescribed at the beginning of the disease, on the first or second day at latest, for the reasons I have sufficiently impressed upon you.

IV.—TREATMENT.

In what form and doses shall you prescribe digitalis? It is not well that we should point out the indications for the use a remedy only, it is also of importance to know how to use this, for a good instrument in the hands of the inexperienced becomes a bad one.

I must remind you, firstly, that I have for some time back abandoned the infusion of digitalis. I do not in any way agree with the opinion of Bernheim, of Nancy, who, in speaking of the treatment of pneumonia, says: "I have never seen digitaline act in those cases in which the simple infusion of digitalis has failed, while I have seen this do good in those instances in which digitaline produced no effect." For the last four years I have employed the crystalline form of digitalis in a solution of the strength of 1 to 1000. This preparation is well borne by patients, it has an invariable and certain action, and its dosage is easily managed. I prescribe at once, some time in the day, 30, 40, or 50 drops of the solution mentioned, the last amount representing one milligramme of the crystallized digitaline, or about four milligrammes of the amorphous principle. This dose will appear perhaps somewhat exaggerated, but nevertheless, it has never produced untoward effect, my especial method of administering it having been communicated to the Société de Thérapeutique. I always prescribe it with care, from the beginning, by itself or in conjunction with an exclusive milk diet, this milk diet opening "a way for the action of digitalis." Objection is often raised to the cumulative effects of the drug, to its slow action and elimination, and hence other cardiac remedies have been advocated as substitutes, but I, myself, have never been able to find an equivalent to this marvellous remedy, without which the therapeutics of the heart would be impossible.

It is time to act against exaggerated views, and to proclaim in strong terms that the cumulative effects, the slow action, and tardy elimination of the drug are, so to speak, superadded qualities. I will say now and again that digitalis is a corrective of and provokes diuresis, thus becoming a safeguard, a shield to the organism. It must be given in large quantities, because it is just then that it cumulates and acts slowly. When you desire to put a patient to sleep, you inject into him at once a centigramme of morphia, and not in repeated doses. When you want to reduce a high febrile state, you must prescribe from 1 to 1.5 grammes of quinine at at once, and not the same quantities in repeated doses during the day. As is the case with quinine, digitalis and all other slow-acting medicaments are not generally given in fractional doses, since such medicaments are divided in the organism itself, owing to the slowness of their action and their tardy elimination. The method of employment of remedies which are rapidly eliminated, such as the bromides and the iodides, is just contrary to the one we have been just considering. You divide the doses, inasmuch as the system becomes often, and for a considerable time, under a marked influence of the drug. In regard to this point I will cite the case of an epileptic suffering from nocturnal attacks, who received, without any effect whatever, eight grammes of bromide of potassium in two doses in the course of the day, but who was completely relieved by two doses of 2.5 grammes each, one given late in the afternoon, and the other at night before the expected attacks.

Digitalis, therefore, must be prescribed in large doses in order to obtain rapid and good effects. My venerable teacher, Potain, has for a long time observed this method of employment, and I administer, like him, in cardiac affections one milligramme of crystallized digitaline at once. However, this, especially in pneumonia, is a maximum dose, and I would not advise you to go beyond it. I, for my part, will not follow the example of a physician of Bucarest, of Petrescu, who fearlessly uses from six to eight grammes of the infusion of digitalis. The innocuity of such colossal doses cannot be explained, unless we admit a poor quality of the plant employed.

For the next two days, and during which also I administer from 40 to 50 drops of the solution referred to, I do not employ any other remedy, nor even the subcutaneous injections of caffeine, because I am always afraid to give another drug whose effects may lessen or antagonize those of digitalis. Therefore, if the adynamia is profound, if the nervous asthenia marked, I do not hesitate to practise hypodermatic injections of ether or camphor, as these are undoubtedly efficacious against a threatening cardiac collapse. I am in the habit of using the following formula:

℞ Sterilized olive oil.....100 grammes,
Camphor..... 10 "

M. Sig. Inject the contents of a common Pravaz-syringe two to four times a day. These injections are not painful, especially if the liquid be injected as deeply as possible under the skin.

Under the influence of digitaline the ventricular systole is strengthened, the pulse becomes very strong, dyspnœa is lessened, the œdematous congestion of the lungs is averted, the bodily temperature lowered; diuresis is

rapidly established, and during a period of four or five days there is taking place an elimination of the toxic substances produced by the infectious disease. Under the power of the drug the arterial pressure is increased, an important consideration in a malady, which, like the grippe, well characterized, and, as I have shown in my researches, tends to produce vascular depression. If in the course of the malady, the indication makes its appearance again, even after the ingestion of the drug, I do not hesitate to re-administer this after the seventh or eighth day, but then in smaller quantities, about 20 or 30 drops, and without considering the presence of albuminuria a contra-indication as is generally wrongly held. In certain similar cases, digitalis diminishes considerably the amount of albumen, and in the infectious diseases, by provoking diuresis, it tends to remove the toxines, whose retention in the organism would be a serious cause of auto-intoxication.

In conformity with the views held at present, an important element must be taken into consideration in all the infectious diseases. I have already spoken to you of hepatic insufficiency. The liver is, in fact, more or less altered; the hepatic cells do not fully exercise their function in arresting or neutralizing poisonous materials, and these, therefore, find their entrance into the circulation. Yet, an auto-intoxication of the organism may be prevented by the kidneys as compensatory organs of the liver, eliminating a great part of the toxines which this latter organ has been unable to destroy. This explains why at this compensatory period the urine becomes highly poisonous, and why this urinary crisis is, as Buchard has remarked, "one of the safeguards of the organism." But the superactivity of the renal structure has its limits as well as its dangers; the constant passage of these toxic and irritant substances produces at last inflammation of the kidney, and the urine is then charged with albumen. Thus the insufficiency of the renal organs is dependent in these cases upon that of the liver, and we have now an albuminuria caused by a glomerulo-nephritis of infectious origin. You can understand then, that here again the object of the therapeutist would be to bring about a urinary depuration by provoking diuresis, and that the indication calls once more for the use of digitalis.

This hepatic insufficiency which plays an important part, often unrecognized in general and febrile diseases, must be combated by two kinds of medication: The one should be directed to enhance the activity of the liver and the kidneys; the other to remove all sources of auto-poisoning, especially that of the intestinal tract. The first indication is met with by the administration of *milk*, since this article of food is diuretic and through such action the toxicity of the urine is diminished; besides, milk contains sugar capable of being transformed into glycogen, and is likewise poor in salts of potash so often injurious to the economy. It is for this reason also that all food containing salts of potash, such as meat and especially broths, should be suppressed. *Intestinal antisepsis* should then be resorted to, and here comes into play the administration of salicylate of bismuth, naphthol, salol, betol or benzo-naphthol. I prefer the latter medicament in doses of 5 to 6 *cachets* of 0.05 gramme each, and I prefer it on account of its non-poisonous properties, its lack of taste, and of its slight diuretic effects.

Intestinal antisepsis must be rigorously practised in all infectious disorders, and especially in influenza, this pestilential malady *par excellence*, as termed by ancient authors. You must not, however, neglect the practice of *buccal antisepsis*, not only in the case of pneumonia, but even in the apparently least serious manifestations of the disease. Bacteriology has taught us that influenza is the resort of a great number of micro-organisms; and it has also been shown that the malady increases the virulence of such microbes. Finally, we have learnt that secondary infections are quite frequent. Now, we can do little against the primary infection; but we are to a certain extent the masters of secondary infections. In an individual suffering from gastric embarrassment, you will observe, after a few days, the development of a pneumonia which you have not foreseen and which you have no reason to fear. In such a pneumonia, the pulmonary affection follows its natural course, when suddenly all the symptoms are intensified, the expectoration becomes sanious and abundant, and you are finally met with all the signs of a pneumonia which has arrived at the stage of gray hepatization. What has occurred in such a case? A secondary infection has been superadded to the primary one. In this patient suffering from gastric disturbance, the pneumococci, normally found in the buccal cavity, have acquired a great virulence; a secondary infection has alighted, as it were, upon the primary disorder and the microbes of suppuration have rapidly completed their work. During an epidemic, in the course and at the onset of a grippal pneumonia, buccal antisepsis must not be lost sight of, and I have but to repeat here

what I have so often told you. To all your pneumonic patients, held under the grasp of influenza, a malady which markedly diminishes the vital resistance of the organism to the action of pathogenic germs, and which so prodigiously exalts the properties of these, you must order every day, and as often as possible, mouth washes and local applications to the deeper parts of the cavity with solutions of corrosive sublimate. Remember, that the *rôle* of the therapeutist does not only consist in curing (and alas! he does not always cure) but in foreseeing and preventing all complications that may appear threatening secondary infection.

I must yet speak of another medicament, *quinine*, whose employment is generally indicated in all grippal pneumonias, but I do not believe in the preventive properties attributed to the drug by certain authors. I am in the habit of prescribing the hydrobromate of quinine, which I consider superior to the sulphate, especially on account of its sedative effects, in dose of from 1 to 1.5 grammes in the morning, in three doses at intervals of half an hour, and this during the period of three or four days at the most. I have often said that this remedy, like digitalis, must be prescribed in large quantities. I have employed thrice daily *cold baths* as recommended by several authors, but I have not obtained good results. When patients have become agitated, it has not been my rule to follow this measure, energetic it is true, but certainly dangerous in a disease in which the heart is constantly being threatened.

Finally, in those cases in which the injections of camphor, ether and caffein appear to be insufficient to combat the adynamia and the nervous asthenia, I have recourse to the use of the *sulphate of strychnia* in doses of 3 to 4 milligrammes a day, either by the stomach, or according to the following formula:

℞ Distilled water.....10 grammes.
Sulphate of strychnine, 0.01 gramme.
M. Sig. Inject 2 to 4 half-syringefuls in a day.

It becomes evident that you must order this medicament in conjunction with other tonics, such as *Todd's potion*, although this is often abused. I, myself, prefer the *kola* preparations, whose tonic and stimulant properties have been pointed out since 1884, in the thesis of Monnet. The formula which I recommend is as follows:

℞ Tincture of kola.....
Tincture of coca.....aa 60 grammes.
M. Sig. A dessertspoonful, 2 or 4 times a day, in a cup of warm and sweetened milk or in a little curacao mixed with a little water. This is an agreeable preparation.

These, however, are accessory measures. Digitalis, quinine, the injections of camphor, ether or caffeine, intestinal, and buccal antisepsis, form the basis of the treatment of all grippal pneumonias.

I have not gone beyond the enumeration of all these therapeutic means, and know full well that I am far from having grasped the whole of such a vast subject, and that I have not spoken of the treatment of the complications. But I have endeavored to demonstrate to you that from a clinical, as well as from a therapeutic point of view, we only see in grippal pneumonias a diseased lung; that there is no such thing as an antipneumonic medication; and that we are satisfied with the application of compensatory therapeutics to which I have already referred, that is, by calling upon the healthy and compensatory organs that these may lend a helping hand to the diseased one. I have, in one word, endeavored to impress upon you the truth of this proposition:

In almost all pneumonias, especially in grippal pneumonias, the disease is in the lung, but the danger lies in the heart and nervous system.—Translated from *La Bulletin Medical*, February 14, 1892.

TETANOID CONVULSIONS IN AN INFANT. OPERATION; RECOVERY.

The *Centrall f. klin. Med.* refers to Dr. T-R. Ronaldson's case in which a healthy child, normally born, but with an uncommonly thick umbilical cord remained in perfect health until the ninth day, when on the eleventh day tetanus developed. On examining the umbilicus it was found black in color and very foul smelling. Symptoms of inflammation were not present. The convulsions occurred from time to time. During the intervals the child seemed to be well enough, and was able to take the mother's milk. The stump was washed several times daily with a sublimate solution, and every precaution was used to prevent a recurrence of the attacks without avail. On the twenty-third day the author performed excision of the navel, which was followed by a gradual disappearance of the seizures, they becoming less frequent from day to day, and at the end of the seventh week the attacks had entirely ceased, and the child was perfectly well. There were no micro-organisms found in the excised umbilical stump.—*Edinb. Med. Jour.*

TUBERCULAR CARIES OF LUMBAR VERTEBRÆ—HIP DISEASE—MULTIPLE SINUSES—SPONDYLITIS.

By H. AUGUSTUS WILSON, M. D.,

Clinical Professor of Orthopedic Surgery in the Jefferson Medical College, Professor of General and Orthopedic Surgery in the Philadelphia Polyclinic, Clinical Professor of Orthopedic Surgery in the Woman's Medical College.

Delivered at the Jefferson Medical College Hospital.

Gentlemen:—I bring before you this morning the little boy upon whom Professor Forbes operated five weeks ago; a case in which there was a tubercular caries of the lumbar vertebræ primarily, and subsequently a tubercular hip-joint which was excised by some physician outside of the hospital. For some reason which will be explained the sinuses persisted, and on last Saturday I laid open the tracks, removed a portion of necrosed bone, and then stitched up the wound. The case at the time of the operation was of very great interest from the fact that there was a sinus just above Poupart's ligament, which seemed to indicate the presence of a Psoas abscess. On opening the sinus, however, it was found to lead directly to the hip-joint, and was not apparently connected with a Psoas abscess. This is of interest because it shows the various directions the sinuses in hip-disease will take. I now bring the boy before you to show you his present condition. He was taken off of the wire bed upon which he was placed after the operation, a few days ago. The wounds are still healing, but they show the characteristic appearance of tubercular granulations. You will observe on the left side a sinus which continues to ooze, and which is probably connected with a carious spine. The site of the operation is in a satisfactory condition, except at one point. You can all see the extensive cicatrization. The leg is in a good position, and is held so, I think, by bony union. The sinus in front is still discharging a very small amount of bone pus. I think from now on a conservative mode of treatment should be observed, for the sites of the dead bone are so inaccessible that it would be unwise to attempt to remove them. Our hope is that by the curative plan of iodoform emulsion the tubercular bacilli may be killed and the progress of the disease arrested.

TRAUMATIC OSTITIS OF HIP AND SYNOVITIS OF KNEE.

This boy you will remember was in our last clinic. You will doubtless remember his shocking condition. His appetite is now greatly improved; his general health also, and he has no pain. The cicatrization is proceeding satisfactorily at all points. We have obtained primary union throughout the wound except at the point of drainage, which I told you would be kept open to afford egress to the small amount of pus that must continue to form. The small bedsore over the coccyx has yielded to our treatment, which consisted of absolute cleanliness and removal of all pressure by the employment of the cotton ring. You can see the character of the union throughout the extensive incision. There has been a decided increase in the deposit of fat in the tissues, showing that our treatment has relieved the drain upon the system, and enabled him to build up. The temperature chart is decidedly improved, though it still zigzags between 99° and 100°, indicating that there is still some constitutional disturbance. The boy is in a good condition, however, as compared to his former condition, and as he further improves other measures for the relief of his affection will be considered.

SPONDYLITIS.

I propose during the balance of the hour giving an introduction, as I might say, to the subject of Potts' disease of the spine. I find that it is necessary to devote a short time as a preliminary to this important subject in order to make its principles rather more clear to you, so that you may understand its importance when cases are before you. Potts' disease is tubercular ostitis affecting one or more vertebræ tending towards a breaking down of the bodies of the vertebræ, thereby producing a peculiar kink or curvature of the spine. The external manifestations of this curvature are so grossly different from those of rotary lateral curvature that all that is necessary to call your attention to the distinction is to show to you these two specimens. In rotary lateral curvature there is no posterior or angular deflection, but a lateral deflection, manifesting itself by a peculiar bulging of the ribs upon one side and a regular deviation of the line of the spinous process, associated with rotation of the vertebral column. This specimen shows the character of the rotary lateral curvature with an elevation upon one side and a depression upon the other, with a rotation of the spinous processes in such a position that the ribs are thrown backward on one side. In marked

contrast observe the changes in this specimen of spondylitis. Here the bodies of the vertebræ are destroyed, and the weight above has caused a bulging of the spine posteriorly. In Potts' disease there is present what there is not in rotary lateral curvature, and that is a *destruction of the bodies of the vertebræ.* I cannot occupy time now by speaking of the nature of the disease further than to say that it is a primary tubercular ostitis rupturing into the joints and destroying the latter; the bodies of the vertebræ become soft, are pressed upon and yielding produce this deformity. There is no tubercular disease in rotary lateral curvature, while Potts' disease is a true tubercular caries of the bodies of the vertebræ. I have in a previous lecture dwelt upon the subject of tubercular ostitis in general, and as all I then said is true of the condition we are now studying, I will not repeat.

Now for the various names of Potts' disease. Just as in hip-joint disease I found it necessary that you should understand the various names by which the disease was designated, so now it again becomes necessary to call your attention to the synonyms under which Potts' disease is recognized. It was Perceval Potts who first accurately described "Some Forms of Paralyses due to Caries of the Vertebræ." He spoke of the impinging of the vertebral column upon the spinal cord as a result of this caries, and as a result of his elaborate paper his name was applied to the disease, as a tribute to his scientific and practical research. Before that, the affection was called hump- or hunch-back, gibbous spine, etc. Before Potts' time the ordinary bone-setters were practically the only ones who treated this condition, and as a result, the diagnosis was rarely accurately made, and no consideration was paid to the prevention of the deformity or its progress. From the time of Potts' first description in 1779 the treatment has necessarily varied very much. The other names of the disease are spondylitis, from the Latin *spondus,* and *itis,* meaning an inflammation of the vertebra. This term describes the pathology of the affection, and hence is a good name to use. It is also called tubercular caries of the spine. Other names are given to the character of the protuberance. The term *kyphosis* is given to the hump, and signifies merely a hump. Hence this name is rarely used in the study of tubercular caries of the spinal column because it is inadequate. I always deprecate the giving of a man's name to a disease, for the reason that it does not describe the pathological condition which is present. It is generally understood now that Potts' disease means tubercular caries of the spinal column. The correct term I believe is *spondylitis,* because it definitely tells what the disease is.

Now as to the causation of the protuberance. One of the clinical stand-bys in a clinical lecture has been the stick I show here, notched to indicate that the bodies of one or more of the vertebræ have been eaten away. Pressure exerted upon the top of this stick held vertically causes a bending of the column, and a hump is produced. Then, unfortunately, the clinical lecturers go further, and say that a straight stick applied to this bent stick as to a bent tree is the principle of the mechanical treatment of this condition. This is incorrect for mechanical reasons. It would be all right could we get our splints or braces around the spinal column itself, and if the spinal column were composed of one piece as the stick is. In caries we deal with softened ribs and with a softened set of costal cartilages; if pressure be exerted on these alone, there will be produced a yielding as is shown in this specimen. The ribs are pressed forward and the costal cartilages spread. If this will happen without support, will not the same thing follow if we try to bridge up the caries parts alone in the manner indicated? To press on these soft ribs will be to bulge them out without affecting the spinal column whatever. The spinal column is held up and the weight of the head borne not by means of guys of stiff material, but by muscles which pull down. The movements of the spinal column are resisted by muscular effort. In caries of the vertebræ, say in the dorsal region, all of the tissues above that spot, namely, the head and shoulders, are tending to cause kyphosis, and the muscles below are increasing this trouble by contraction. The rational treatment, therefore, would seem to be to remove this pressure. By lifting the superincumbent weight I can overcome the deformity in this stick. If I take this spinal column and put it in the upright position in which there is a curve produced, it is the head and shoulders which produce the curving. If, however, I can put it in such a position that there will be no head weight, there will be no kyphosis produced. Hence, the position of recumbency is necessary in the treatment of this disease, because in that position only is the affected part relieved of the superincumbent weight. I do not say that you must keep the patient in bed to do this, for as the course of the disease runs over two to five years such a procedure would increase the constitutional weakness of the patient. By

mechanical means we can *maintain the position of recumbency* and yet allow the patient to be around gaining the advantage of a outdoor life. If you adopt the principle that mechanical support to be thoroughly efficacious must have for its object the mechanical maintenance of the position of recumbency you will have a standard to guide you.

There are three forms of apparatus in use about which I shall speak. *First*, that which is applied to the patient's body below the seat of the disease only. *Secondly*, where a sort of bridging of the diseased portion is attempted. The apparatus supports above as well as below the site of the disease. Here there is a firm foundation and the tissue of the splint prevents the ribs from bending. The *third* form I believe to be the best and most rational, in that its object is the relief of pressure and immobilization, and it therefore maintains the position of recumbency. First and foremost there is, just as is the formation of any architectural structure, a good foundation. In taking the weight of the head and superstructure away from a caries of the spine it is necessary to have a good foundation upon which to rest the apparatus and the load it is to carry. This apparatus is one of the forms employed; it can be made out of leather, felt, steel or other material, must fit thoroughly and comfortably the hips so as to prevent any slipping. Then, having secured a foundation, a couple of steel bands are used to carry the foundation up to the point where the superstructure can be applied. Then the apparatus is used to lift the weight of the head and shoulders from the diseased parts of the column. By means of a minerva or collar the head and chin rest upon the foundation and not upon the spinal column. A jurymast will accomplish the same thing. It consists of a rod carried over the head with a sling applied so that the same object may be accomplished. Thus various methods may be used, but what I wish is that you should understand the principle and ignore the material of which the apparatus is made. In such apparatuses the position of recumbence is maintained for the reason that the spinal column is allowed to maintain its normal position free from weight. There is also a freedom from mobility. If this position is accomplished and maintained, you can have a cure just as you can in any other form of tubercular bone disease. Rest and immobility are necessary in all these cases. Osseous recovery in tubercular-spinal disease can be secured if the case is treated in the proper manner. Other forms of apparatus adopt the crutch form of support. There the weight rests on the axillæ, and the weight of the shoulders only is taken off. It is wonderful how far you can elevate the shoulders while the head sinks down, showing that the weight of the head is not removed. An immense amount of extension of the shoulders can be made before the weight of the head is removed. One of the most difficult things in the treatment of these cases is the securing of a suitable foundation. You can see how small the pelvis is in a child. If necessary the foundation may be extended down the legs in order to secure firmness. One of the methods often resorted to in the treatment of caries of the spine is the application of the plaster of Paris bandage. Professor Louis Sayre, of New York, has rendered a lasting service by the introduction of the plaster of Paris jacket in this disease. He advocates a jacket which is applied by him with perfect satisfaction in most cases. But the trouble is that the jacket has apparently been looked upon as possessing curative properties in itself, and hence has often not been properly employed. Plaster of Paris of itself I need hardly assure you has no curative effect; it only acts by mechanical action alone. Only last week a profound case of Potts' disease was sent to me in which the jacket was so short and loose that it slipped over the pelvis, and the doctor very ingeniously had applied straps over the shoulders to hold it in position. The weight of the apparatus was six pounds, and this was added to the shoulders already bearing too much weight. I could only account for the use of such a contrivance by thinking that the physician was imbued with the idea that the plaster of Paris must have been curative in itself, it certainly did not exert any beneficial mechanical action. Plaster of Paris as used by Professor Sayre is an entirely different matter from the plaster of Paris as used by a large number of physicians. Professor Sayre first suspends the patient so as to secure the position of recumbency. Then he applies first of all a good foundation. He presses in around the waist and on this applies a proper amount of superstructure, and applies it for mechanical reasons to accomplish a mechanical result. We can apply plaster of Paris to a broken forearm in the same manner as it is often applied to many cases of spinal disease, by merely applying the plaster above the fracture and not below. If the apparatus is only carried to the seat of disease we are apt to overlook the fact that the head is an important factor in the development of the deformity.

One of the methods of knowing that your object has been attained is by seeing that the child's symptoms are overcome by your apparatus, and unless this be accomplished you may be sure that its use is harmful or at least is doing no good.

COMMUNICATIONS.

A YEAR'S WORK IN MINOR SURGICAL GYNÆCOLOGY AT THE KENSINGTON HOSPITAL FOR WOMEN.*

By CHARLES P NOBLE, M D.,

Minor surgical gynæcology, embracing the surgery of the pelvic floor, vagina, bladder, and uterus—excluding hysterectomy—has not received much attention at the hands of recent writers. This is partly because the attention of gynæcologists has been devoted to the marvellous strides which have been made in abdominal surgery, and partly because this field of work is not so brilliant as that of abdominal surgery. It is true that minor gynæcological surgery is not brilliant, but it is very important, and it seems to me that it is in some danger of being neglected by the surgeons of to-day. This fact has led me to report my last year's work in minor surgical gynæcology at the Kensington Hospital for Women, and to make certain observations on the various operations named. The following operations have been done:

Removal of vaginal cyst (post cervical)	1
Clitoridectomy (nymphomauia)	1
Excision of carcinomatous nodules (secondary after removal of breast)	3
Uterine polyps (removed)	2
Lipoma (removed)	1
True pelvic abscess (drained after exploratory section had excluded disease of appendages)	1
Atresia of vagina (divided)	1
" " vulva "	1
Cancer of cervix—curretting (death fr m uræmia)	1
Amputation of cervix—cancer, 1; procidentia, 2	3
Anterior colporrhaphy (oval)	1
" " (Stotz)	2
Perineorrhaphy (Hegar's)	1
" (Emmet's)	17
Trachelorrhaphy	6
Dilatation and curetting	18
	60

One death occurred in a case of advanced carcinoma of the cervix, which was thoroughly curetted by Dr. Kelly. Death followed on the eighth day from "cancerous uræmia." This poor woman had been insane for some weeks—the insanity being due supposedly to absorption of septic matter from the decomposing cancer. The operation was done with the hope of relieving this, and also to get rid of the necrotic mass. The other operations in the report were done by myself. The technique employed was quite similar for all cases. The patient's bowels were well cleared out the day before the operation, and moved by enema the morning of the operation. In addition, the patient had a full bath and a sublimate vaginal douche. Operations were done under ether-anæsthesia in the dorsal position, with the Robb leg-holder and Kelly perineal pad in use. The vulvar region and vagina were well scrubbed with soap and water, the vulvar hair was shaved, and the parts were well douched with sublimate solution. In this way an aseptic field was secured; all operations were done under irrigation with boiled water, sponges not being used. This technique is a little troublesome, but the results secured amply compensate for the outlay of time.

I have made it an invariable rule to *re*-examine all patients before beginning the operation. This can be done most thoroughly when the patient is anæsthetized. If the uterine appendages are found inflamed and adherent, any proposed operation upon the uterus is abandoned. I believe this to be the only safe rule of practice.

For sutures, silk, catgut, and silkworm-gut have been used. For general purposes I like silk; but it should not be used where the sutures cannot be removed in one or two weeks. Catgut I have found very useful for sutures having but little strain to bear, as, for instance, the upper sutures in perineal operations. Silkworm-gut has the advantage that it is non-absorbent; hence it is to be preferred where sutures must be left in a long time, as, for instance, in the cervix, when the cervix and perineum are repaired at the same sitting. It has the disadvantage of being stiff, which property makes it somewhat hard to remove, and gives the patient some pain. After operations the vagina is carefully dried, a pencil of iodoform (25 grains), together with a strip of iodoform gauze, is introduced, the vulva is sprinkled with a powder of iodoform (1 part) and boric acid (7 parts), and then a cotton pad is placed over the vulva—held in place by a T-bandage. For perineal operations the urine is drawn for two days; after which the patient is allowed to urinate. The gauze is removed after forty-eight hours; after which a sublimate douche (1 : 2,000) is given once daily. The bowels are moved on the second day and regularly thereafter. An abundant soft diet is permitted. The external sutures in perineal operations are removed about the eighth day; the internal sutures a the end of the second week. When the cer

*Read before the Philadelphia County Medical Society, March 9, 1892.

vix has been repaired at the same time, the cervical sutures are removed at the end of the third week or even later. One should err on the side of leaving the sutures in long rather than that of removing them early.

Patients having perineal operations are permitted to sit up in two weeks; those having a curetting, in three or four days; those having a trachelorrhaphy, in a week, etc.

The secret of success in plastic surgery is good asepsis, and careful, painstaking, and accurate denudation and suturing. I have never failed to secure good union, which has always been primary throughout, with two exceptions—one stitch-hole abscess and one small hæmorrhage (hæmatoma).

DILATATION AND CURETTING.

Within the past ten years professional opinion concerning these operations has fluctuated widely. Before the antiseptic era curetting was considered a dangerous operation. Its danger at that time I feel satisfied was due partly to lack of antiseptic measures, and partly to bad diagnoses. At that time our knowledge of the diagnosis of chronic salpingitis was very imperfect, and many accidents (peritonitis) resulted from operating on the uterus when the tubes contained pus or other septic fluid. Since the antiseptic era in the hands of men capable of making a diagnosis of uncomplicated disease of the uterus, and of excluding chronic pelvic inflammation, these operations have been done with impunity. Of late, the legitimacy of the operations has been questioned by Dr. Joseph Price, on the ground that many cases of salpingitis and pus tubes have come under his care in which dilatation and curetting has been done. This fact is no argument against the legitimacy of the operations, nor against the fact that, when properly done in uncomplicated cases, the operations are perfectly safe and free from danger,

Did the women seen by Dr. Price (and by others, including myself) have the tubal disease before the uterus was dilated or curetted? Were the operations done under rigid asepsis? I believe that blunders in diagnosis and blunders in asepsis should bear the blame in these most unfortunate cases, and not legitimate surgery. In my own hands no such untoward results have occurred. On the contrary, under the strict limitations laid down, my confidence in the value and safety of the operations increases as my experience grows.

DYSMENORRHŒA.

Three cases of dysmenorrhœa, due to partial development of the cervix, with anteflexion, and characterized by "cramps" during the flow, were treated by dilatation. Dilatation in this class of cases has always given good results. The cause of the "cramps" is a poorly developed cervix with a narrow canal, whose calibre is further lessened by the anteflexion.

A broader experience has induced me to use the dilator for dysmenorrhœa much less frequently than formerly. I consider it absolutely contra-indicated if there be tubal inflammation, and believe that it is of little use in relieving pain, unless the latter be distinctly intermittent and cramp-like in character.

The pains accompanying menstruation due to inflammation of the uterine appendages, or of the uterus, or due to a depressed state of the blood, with pelvic neuralgias, are not benefited by dilatation, and in such cases it should not be done.

ENDOMETRITIS.

Fifteen cases of uncomplicated endometritis have been treated by dilatation and curetting. Nine of these were cases of fungoid endometritis with resulting uterine hæmorrhages. I believe that this procedure best meets the indications in all cases of uncomplicated *chronic* endometritis. By removing the thickened portion of the diseased endometrium and providing a freer vent for the uterine secretions, most cases of endometritis can be cured promptly, and the remainder are much improved. The number of cases in which it is necessary to make intra-uterine applications is thus much reduced, and these women are saved the necessity of undergoing a prolonged course of painful intra-uterine treatment. By promptly curing women with chronic endometritis another important point is gained—the disease is cured before it spreads to the tubes.

The results in my hands have been most satisfactory in cases of fungoid endometritis, especially those of short duration, resulting from abortions. Cases of chronic endometritis with purulent leucorrhœa have been most intractable, and in these cases it has been necessary to make weekly applications to the endometrium (by means of the applicator) of pure carbolic acid, Churchill's tincture of iodine, or a saturated solution of chloride of zinc for some weeks *after* the curetting. I wish to call attention to the small number of cases of uncomplicated endometritis in this series. Omitting the fungoid cases, there were 6 out of 128 women admitted to the hospital. This is about the average in my practice.

In fungoid endometritis I have found the curette so valuable, and other methods of treatment (in marked cases) so futile, that I am unable to understand how these gentlemen who oppose the use of the curette treat these cases. The only other resort is electricity; but the curette will accomplish in a few minutes what it requires weeks or even months to accomplish by electricity.

The results obtained by the curette in uncomplicated endometritis are so good that of late, forgetting the teachings of past experience, certain operators have proposed to treat cases of endometritis complicated by tubo-ovarian inflammation in the same way. It seems to me that careful men cannot protest too strongly against such treatment. In the first place, the danger of setting up fresh salpingitis and peritonitis is acknowledged (except by the few) to be great; and in the second place, should the endometritis be cured (which is doubtful because of pelvic congestion kept up by the tube-ovarian inflammation), the graver diseases of the appendages remains. The wiser plan, if the appendages are diseased, is first to remove them, and then actively treat the endometritis; or if the appendages are but slightly diseased and do not require ablation, to treat the patient by applications of iodine to the vaginal vault, and the use of glycerine tampons, at the same time using every measure to improve the local conditions by general medication.

It happens not infrequently that when the inflamed uterine appendages are removed, an endometritis is left which causes the patient some annoyance. These cases are often reported by those hostile to modern surgery as showing that the abdominal section has failed to cure the patient. These gentlemen have a mental strabismus, and do not see that the section has accomplished the end aimed at, the ablation of the diseased uterine appendages. Whether this alone will cure the patient depends upon whether the particular patient has any other disease. If she has an endometritis, this must be cured; if anæmia, or indigestion, or malnutrition, these must be treated.

I wish to protest against the view that endometritis as a rule causes much distress, except the annoyance of leucorrhœa, unless it induces hæmorrhage. Where women having endometritis suffer much pelvic pain, and are semi-invalids, the cause of the pain or invalidism is to be sought elsewhere—in the uterine appendages, or in the vital organs, or blood state. It is a narrow man who attributes all the symptoms complained of by women to disease of the pelvic organs, and who forgets that women have an unstable nervous system, easily influenced by morbid conditions of the general economy.

In discussing endometritis it should not be forgotten that other conditions besides endometritis can cause a discharge from the uterus. Whatever will cause congestion of the uterus will cause uterine discharge. For example, subinvolution, constipation, feeble heart, lazy habits, malnutrition as from phthisis, erotism, etc. Treatment addressed to the causative disorder will stop such uterine discharge. This class of cases calls for no treatment of the endometrium.

STOLZ'S ANTERIOR COLPORRHAPHY.

This operation has been done twice during the time covered by this report. It is especially adapted for cases of procidentia in which cystocele is a marked feature. The cases have been treated with most gratifying success by amputating the cervix above the vaginal junction, doing Stolz's operation on the anterior vaginal wall and Emmet's operation on the perineum, the combination of operations being done at one sitting. I have had but one failure in my experience. This was in the person of a woman having complete procidentia, whose tissues had undergone marked fatty degeneration.

PERINEORRHAPHY.

One Hegar's operation was done on a woman having a patulous introitus. Seventeen operations were done after the manner of Emmet for injuries to the pelvic floor, involving laceration of the levator ani muscle and loss of pelvic support.

It seems strange to me that men who are familiar with the anatomy of the pelvic floor, and with the nature of the injuries it sustains during labor, can differ so widely concerning the nature of the operation required to repair the injuries sustained. Not to consider the lacerations extending into the bowel, there are two general classes of lacerations of the pelvic floor:

1. Lacerations involving the vulvar commissure, and extending scarcely to the vagina, scarcely beyond the plane of the hymen. These are the insignificant lacerations, which at most give rise to a gaping *introitus vaginæ*, but which involve no appreciable loss of pelvic support. Such lacerations are median, and involve no very important muscular structures. The bulbo-cavernosus and the transversus perinei muscles may be divided, but the laceration does not extend far enough up the vagina to reach the levator ani.

Usually it is indifferent whether such lacerations are closed or not. The result to be gained is scarcely sufficient to compensate a woman for submitting to a secondary operation. In my opinion, however, even such lacerations should have a primary perineorrhaphy. If a secondary operation is done, the Hegar operation best meets the indications. The flap-splitting method will answer, but it leaves an ugly fold of tissue at the orifice of the vagina.

2. Lacerations extended along the vagina, and involving more or less of the levator ani muscle or muscles and the deep fascia, according to the extent and depth of the lesion. Such tears, as a rule, not only involve the commissure of the vulva, as in class 1, but also extend up the vagina, aud without exception extended up one or both sulci. They are never median. The tough pelvic fascia seems to deflect the laceration to one or other side. But whatever the explanation, it is a fact that deep, extensive lacerations do not extend up the middle line of the vagina, but up one or both sulci. Sometimes the injury is wholly in the vagina, and the commissure of the vulva remains intact. Hence these tears are Y-shaped when the commissure of the vulva is involved and the tear extends up both sulci. They are Y-shaped when the commissure is involved and the tear extends up one sulcus (one arm of the Y is not represented). And they are V-shaped when both sulci are involved and the commissure escapes (the leg of the Y is not represented). The principal tissues involved in the injury are the levator ani muscle or muscles and the deep fascia. The injury extends two or three inches from the plane of the skin perineum. As is well known, pelvic support depends upon the integrity of the levator ani muscles and the pelvic fasciæ; hence the loss of support resulting from the injury is in direct ratio to its extent. When the lesion is extensive, the bladder, bowel, and uterus prolapse.

A very careful and somewhat extensive study of this subject from the clinical side has convinced me that the foregoing propositions represent the facts in the case, and are not theoretical. I believe that the reason certain gynæcologists of prominence do not accept this pathology is because they do not see much of obstetrics, and they have not studied the nature of lacerations immediately after labor. Anyone can convince himself of the truth of the foregoing statements by studying recent lacerations.

(For the sake of completeness, submucous laceration or over-stretching of the levator ani muscle may be called class 3.)

For the cases embraced under class 2, no operation will yield such results as the Emmet operation. The important lesions are in the sulci of the vagina, and can only be reached by denuding aud suturing the sundered tissues in the sulci. As a means of narrowing the vagina it has the further advantage of making use of the natural folds of that canal. The walls of the vagina fold upon themselves in such way that the lines of contact in transverse sections make the letter H. The sulci of the posterior wall represent the lower half of the legs of the H. It will be noticed that the walls of the sulci lie naturally together, so that, if they are denuded and sutured, the parts come together surface to surface. This is a very positive advantage in securing strong union, in addition to the advantages of raising the posterior wall of the vagina against the anterior, and of making a new *mediate* attachment of the vagina to the levator ani muscles.

I need not dwell upon the advantages possessed by the operation in cases of well-marked rectocele, in which the sulci are very deep. In no other way can the rectocele be so well rolled into the vagina.

My experience with the operation embraces some fifty cases. The results have been uniformly good, with one exception—the case of procidentia already referred to.

The other operations which are recommended for the cure of this class of lacerations are the median operation of Hegar (or some slight modification of it) and the flap-splitting operation of Tait.

Median operations are based upon the theory that the injury sustained is rupture of the perineal body, and that the operation is to restore this body. Time will not permit me to discuss this question *in extenso*. The nature of the injuries has been considered, and they are lateral, not median. The old theory of the nature and function of the perineal body has been disproved by Emmet, whose views I accept; hence it appears to me that the indifferent results secured by median operations are due to the fact that they are based on a false conception of the anatomy and of the injuries of the pelvic floor.

The advantages of the flap-splitting method are even less than those of the method of Hegar. In the rules laid down for performing the flap-splitting operation, we are told not to make the incisions deeper than a half-inch (from the surface of the skin perineum); that is to say, lesions situated further up the vagina than one-half an inch from the skin surface of the perineum are not

affected by this operation. Inasmuch as the entire levator ani muscle lies above this plane, it is evident that the Tait operation is worthless in the class of lacerations under consideration. The Tait operation accomplishes just about what the old Baker-Brown episiorrhaphy did—it narrows the orifice of the vulva.

What I have said about this operation is based upon the anatomical considerations involved and upon the results obtained by a prominent professor in this city. At least twelve patients who have been operated upon by him have been seen by me at the clinic for diseases of women at the Northern Dispensary. All had a narrow vulvar orifice, and all had more or less rectocele, with deficient pelvic support, and the symptoms complained of before operation. My personal experience embraces one case, which was sufficient to demonstrate to me the lack of anatomical basis in this operation.

TRACHELORRHAPHY.

Trachelorrhaphy was done six times. Experience adds to my appreciation of the value of this operation in appropriate cases. I am satisfied that the dangers and failures to achieve good attributed to it by some operators depend upon poor judgment in the selection of cases.

Either insignificant lacerations are repaired or lacerations complicated by inflammation of the uterine appendages are operated upon. In the first case the laceration caused no symptoms, and its repair relieved none; in the second, if the patient escaped a peritonitis as the direct result of the operation, she continued to suffer from the morbid condition of the appendages.

SUPPOSITORIES FOR CHRONIC PROSTATITIS.

For chronic prostatitis, Oberlander recommends the employment of a suppository containing:

℞ Iodoformi.....gr. vij ss–xv.
Solve in
Ol. amygdal. dulcis.....q. s.
Adde
Ol. theobromæ.....q. s.
—ut ft. suppos. no. x.
S. One to be introduced at night following an intestinal evacuation.

The oil of sweet almonds increases the absorbability of iodoform. The proportion of iodoform in each suppository is slowly increased from three-quarters of a grain to a grain and a half. In susceptible individuals larger quantities may occasion toxic symptoms.—*Deutsche med. Wochenschr.*, No. 53, 1891, p. 1435.

ARTIFICIAL FEEDING OF INFANTS.

By WM. A. TREMAINE, M. D.
PROVIDENCE, R. I.

Artificial feeding of infants demands our serious consideration. We have, as Dr. Meigs puts it, two ways of artificial feeding, one empiric, the other scientific, and the physician is compelled every day to choose between the two. If he follows the first method there is a wide latitude, with a possible hope of favorable result at the end. Scientifically considered, it is desirable to approximate the composition of human milk.

As the nursing baby takes milk from its mother it is germ free. This result is easily obtainable. Much more stress has been laid upon the method of sterilization than the preparation of the milk, and we have often left out of sight what is certainly of as much importance as the simple steaming. Milk sterilization is certainly becoming a recognized principle. The method of steaming is probably so familiar to us all that it needs but passing mention. It has been claimed by some writers, that the milk during this process becomes "devitalized," but how this rather vague claim can be established is uncertain. Up to the present date probably the most reliable analyses of mothers' milk are those quoted by Rotch in *Keating's Encyclopedia*, of Forrester, Meigs, Harrington and others. In these tables as a mean result the albuminoids are just at 1 per cent., or possibly at one and two-tenths of one per cent. Dr. Meigs stated nearly ten years ago that human milk never varied much from 1 per cent. of albuminoids, and that he has never seen any reason to recede from this statement. Many other analyses have been made placing the percentage at a much higher rate, but according to the best authorities these analyses are unreliable. In cow's milk albuminoids range from 3 to 4 per cent. Without dispute cow's milk then needs dilution in order to approximate the amount of albuminoids in breast milk. It makes but little difference what the diluent is, providing the dilution is accomplished. Water, barley water, lime water can be used indifferently as regards the formation of the curd.

Mother's milk is slightly alkaline; cow's milk is slightly acid, and personal experience has taught me that the degree of acidity varies much. Between Meigs, Keating and Rotch there has been much difference of

* Read before the Providence Medical Association, February, 1892.

opinion as to the means to be used for changing this normal cow's milk to resemble the slightly alkaline mother's milk. Dr. Rotch used only $\frac{1}{16}$ lime water of the total volume to accomplish this result. Meigs recommends $\frac{1}{4}$ of the total volume, and says his clinical experience will bear him out in his statement. Keating very justly remarks that when you consider that in a pint of lime water there are only 11 grains of lime, then two tablespoonfuls would only contain about one-third of a grain. Can this be sufficient to correct undue acidity or to supply lime to the tissues? Roughly stated, Keating's plan is to add to the milk bicarbonate of soda and potash with chloride of sodium in the form of a tablet, the whole to be afterwards steamed. Rotch recommends steaming the mixture first, and adding the lime water.

Does this procedure carry out the principle of antisepsis? We practically add to a supposed sterile fluid a certain quantity of liquid which may have been exposed to the atmosphere for an indefinite time.

The lime water cannot be added before steaming, because the temperature of 212° F. would precipitate the lime. When it is added before steaming, the milk will often turn a light brown or reddish color. This result I have obtained myself where the directions were not perfectly followed. Dr. Harrington explains this as the action of the lime water upon milk sugar at the steaming temperature. He adds, however, that at the beginning there is a slight alkalinity which disappears entirely at the end of the operation, so that the mixture is rendered sterile but not alkaline. Keating mentions some very interesting experiments regarding the effect of lacto-phosphate of lime on the curd of cow's milk. Briefly stated, he added hydrochloric acid to two portions milk; one containing $\frac{1}{2}$ grain of lacto-phosphate of lime, and the other nothing but the pure milk.

In the first case the resulting curd was smooth and creamy, and in the second case, it was lumpy and irregular. Repeating these tests my experience was unsatisfactory until the cause of failure became evident. Fresh morning's milk tested immediately showed corresponding results, while milk which had been standing all day, and was perceptibly acid, showed but little difference in the curd. This seems to emphasize the caution to sterilize as soon as possible after milking. The source of the milk as we know is of vital importance. Cows fed on brewery grain or silo will yield milk much more acid than those fed in the ordinary way.

One writer gravely remarks that filtered water is used ordinarily in the preparation of lime water, not boiled or distilled water. My experience is that with most apothecaries in this city aqua Pawtuxensis is used to answer all requirements. (Pawtuxet River water is our only supply, and decidedly not germ free.)

Brush, in the *New England Medical Monthly*, questions the use of commercial sugar of milk, and says that one of the faults of the physiological chemist is that he makes no distinction between a substance existing in a natural condition and that substance eliminated and isolated by chemical means. Thus the sugar of milk of commerce and the sugar of milk as it exists in that fluid are regarded by chemists as one and the same thing. This he thinks is not the truth. The sugar of milk in that fluid is all assimilated while the milk sugar of commerce when added to baby food is eliminated both by the kidneys and the bowels. He says he never found sugar present in the urine or fæces of nursing babies, but in three cases of infants fed with mixtures containing commercial milk sugar as recommended in Meigs' mixture he always found sugar in the urine and fæces by Keating's test. He suggests a return to the use of cane sugar. Meigs uses $17\frac{3}{8}$ drachms to eight ounces of the mixture. It would seem as if the amount in Meigs' mixture was rather excessive, but up to the present date the use of milk sugar seems to be the most reliable.

Regarding the fatty matter, the average is about 4 per cent. both in cow's and mother's milk. After dilution the proportion of fat in cow's milk becomes diminished. This proportion must be restored by the addition of some fatty matter, preferably cream. The cream from fancy cattle, Ayrshire or Alderney, is apt to be too rich in fats. The ordinary mixed herd milk is not so apt to vary in percentage. The centrifugal cream of which Dr. Rotch speaks (20 per cent. fat, diluted $\frac{1}{4}$ or $\frac{1}{3}$) is probably available only in the larger cities. Frolowsky has shown that the activity of the stomach's growth is very great in the first quarter of the first year, very slight in the second quarter, and moderate in the last half of the year. The weight of the child seems to be of more importance in calculating the requisite amount of food necessary, rather than the age. One-hundredth of the natal weight plus 1 gramme for each succeeding day for the first month is the rule suggested from the investigations at the Children's Hospital in St. Petersburg, and seems to be recommended by most writers on

this subject. Thus for a baby weighing 7½ pounds you would give one ounce of food and add 15 grains for each succeeding day during the first month. From this basis Rotch devises a schedule giving amounts and intervals of feeding for ages from birth up to ten months. This schedule is subject to great variation. Dr. Rotch cites a case under his care of an infant for six weeks whose general development and weight corresponded to one of 12 weeks, so that it was evident that two ounces of food, the usual allowance of food so far as the age was concerned, was not enough, and its weight indicated a gastric capacity of four ounces which it took and digested easily. In institutions sterilization of milk has gained great credit. In private practice it is not always so easy to bring mothers to a proper understanding of its value and importance. In the first case the patients are under absolute control. Exposure of the milk at the continued high temperature certainly renders it safe as regards germs, thus far we accomplish a great deal. My individual experience has taught me that preparation of the mixture itself as regards alkalinity and tissue formation is equally as important.

DISCUSSION ON PHAGOCYTOSIS AND IMMUNITY.*

At the Pathological Society of London, March 15th, 1892.

By M. ARMAND RUFFER, M.D., Oxon.

When beginning their remarks on immunity and phagocytosis Professor Burdon Sanderson and Dr. E. Klein stated that they could not accept Professor Metschnikoff's views. I will imitate their candor, and define my position in the same manner, by stating at once that I accept Metschnikoff's theory in its entirety.

Not one of the speakers has explained what he means by immunity; and surely this is the first point to decide. Immunity from a given disease means freedom and exemption from that disease. As far as I am aware, there is no animal, whether naturally resistant or protected by artificial means, which cannot be killed by the introduction of a specific microbe, provided a sufficiently large dose be used. To talk of an animal being immune against a given microbe is to speak of something which does not exist, and, although I must confess to having used the word myself, I would in future rather talk of animals naturally resistant and artificially protected.

Now when a naturally-resistant or artificially-protected animal is inoculated with a virus, I believe that the destruction of the micro-organisms in that animal is accomplished by the amœboid cells, which, for the sake of convenience, we will call phagocytes. I am not aware that Metschnikoff, or any of his pupils, ever said that this was the only cause of the increased resistance of such animals. Metschnikoff certainly never said so, but in his writings and in conversation he has simply stated—and indeed proved—that the process of phagocytosis was *one* of the most important factors in the acquired or natural resistance of a given animal against a given micro-organism.

Dr. Woodhead has already stated what we know of the origin of phagocytes, and I would not enter into the discussion of this question were it not that I must make a personal explanation. I have not said anywhere that *all* microphages, epithelioid cells, etc., were derived from leucocytes; what I have said is that in the cases I have observed the macrophages were derived from small lymphocytes. Were any proof necessary that such an origin of plasma or epithelioid cells is of no infrequent occurrence, I would point out that the development of these cells can be seen in the intestines of various animals, where they wander into the epithelium layer; that they have been found in the blood vessels; that when vermilion is injected into the veins of an animal, similar large cells seize on the powder circulating in the blood and carry it into the neighboring tissues—into the medulla of the spleen or alveoli of the lungs, for instance; that no such cells are present in the alveoli of a newly-born guinea-pig until they have been attracted there by some kind of noxa; and, lastly, that in invertebrata the transformation of an amœboid cell into a fixed cell has actually been followed day by day in the living animal.

Let us, however, pass at once to what happens when wandering cells have taken bacilli into their interior; for there can be no doubt that leucocytes have that power, and that the organisms contained in cells undergo some kind of destruction. That is a matter of observation which everyone can notice for himself who possesses a good lens, a drop of frog's lymph, and a few anthrax bacilli.

In the first place, see what happens when a protected or non-protected animal recovers from an infectious disease, or even when it dies after having resisted the malady for a considerable time. In all cases which have

*Continued from issue of Reporter of April 2d.

been studied up to the present, phagocytosis is a well-marked phenomenon. Slight, or even absent, when the animal has no powers of resistance against a given microbe, it increases with a more resistant animal, or when an animal has been artificially protected, and reaches its maximum when the disease is essentially chronic, as in leprosy and tuberculosis. Lately I have been studying human pneumonia from this point of view, and I can safely say that the human lung in this disease exhibits, in their exquisite forms, all the phenomena of phagocytosis.

Dr. Klein, in his able criticism of Metschnikoff's theories, lays special stress on the fact that, in several instances, the process is reversed, and that the leucocytes are destroyed by the bacteria, and not the bacteria by the leucocytes. This he considers a fatal objection to Metschnikoff's theory. As far as I am concerned, I may state that, in almost every one of my papers, I specially mentioned that a large number of amœboid cells perished in the fight. I have shown this to take place in the healthy rabbit's Peyer patch, in the diphtheritic membrane, in actinomycosis, in tubercle, in *charbon symptomatique*, etc.

I will meet Dr. Klein on his own ground, and take as examples two of the very diseases which he himself has mentioned as proving the fallacy of Metschnikoff's theory —namely, leprosy and tubercle. In many particulars these two diseases resemble each other strongly, for both are caused by a hard resistant micro-organism, and, pathologically, both are characterized by the fact that the micro-organisms, whenever present, set up intense inflammation.

Let us make a section through a leprous nodule, and stain it in the usual manner with logwood and carbol-fuschine. I need not enter into the description of the epithelioid and giant cells always to be met with in leprosy, but at once examine the processes taking place in these cells. In some cases such cells, when crammed with bacilli, undoubtedly die, and this death is indicated by the degeneration of their nuclei, the vacuolization of the protoplasm, and the apparent proliferation of the characteristic bacilli in the cells. That is one side of the picture, but let us look at the other side. In some of the cells the bacilli lose some of their definite outline and fuse together into a hard, solid, resistant mass, in which no structure is discernible even when use is made of the most delicate staining reagents and the highest powers at our command. In a later stage this hard resistant mass gradually breaks up and loses its power of retaining staining matter, until nothing is left in the cell but a clear space, which may be either a vacuole, or possibly a kind of membrane with which the bacilli have surrounded themselves. On the one hand, therefore, we can follow the victory of the bacilli over the cells, and, on the other, we have that of the cells over the bacilli. True, in the large majority of cases of leprosy, the bacilli gain the victory, but we are not justified in thinking that the chronic character of the disease, which may last for months and years, is due to the way in which amœboid cells incorporate the bacilli and destroy a large number of them? Unfortunately, the bacillus has means of defence of its own, and thus frustrates the beneficent endeavors of the cells.

It is an admitted fact that in cases of tuberculosis bacilli are often found in epithelioid and giant cells, and there is not the slightest doubt that these cells frequently succumb in the fight. Signs of degeneration are found in microphages, mono-nucleated, epithelioid, and giant cells, with a frequency which can leave no room for doubt. But what is not so easily observed is the other side of the fight, in which the bacilli perish. Metschnikoff has shown that signs of the encapsulation, decay, and death of the bacilli are of the most frequent occurrence in the giant cells of tubercle, and more especially in the giant cells of those animals which exhibit a strong resistance towards the bacillus of tubercle. In man, indeed, such forms of encapsulation are met with in the more chronic forms of tubercle, such as old scrofulous glands or calcified nodules in the lungs. In many cases of tubercle, therefore, the bacilli prove too strong for the amœboid cells, but that in many others the cells are victorious is proved by the frequency with which cured tuberculous lesions are found at the *post-mortem* examination of patients dying from some other disease. As Dr. Klein has said, in these diseases a great many of the leucocytes perish, but he might have added that the destruction of the bacilli is even more marked than that of the cells.

I am willing to allow the accuracy of Dr. Klein's experiment, when, on injecting a quarter or half a syringe of fluid containing anthrax spores or anthrax bacilli, he finds the anthrax bacilli in the blood a few minutes afterwards. Indeed it would be wonderful were it not so, for the frog's phagocytes are able to arrest a certain number of bacilli, but not an immoderate number; they will arrest enough bacilli to kill a mouse, but not the number of micro-organisms

which would kill an elelephant. And similiarly with vermilion. In my experiments I injected one drop of saline solution holding vermilion in suspension, and found that it was absorbed through the agency of leucocytes. Had I injected a quarter or half a cubic centimetre, the vermilion might possibly have penetrated directly into the blood; but I hold that it is not a satisfactory experiment to inject into the lymph cavity of a frog a large quantity of fluid, when the object in view is to study the absorption of solid particles.

In a former paper I have shown that in animals exhibiting some resistance against the bacillus of Chauveau, the disease was strictly limited to the point of inoculation and its immediate neighborhood. When, however, from any cause, physical or chemical, the amœboid cells were prevented from approaching the virus, the disease became general and the animal died. Dr. J. H. Walker and myself have recently obtained one more confirmation of this law, as shown by the following experiments* with another micro-organism.

If an adult guinea-pig be inoculated subcutaneously with 0.25 cubic centimetre of a pure culture of the bacillus pyocyaneus, an abscess slowly forms at the point of inoculation. Twenty-four hours after the injection the point of inoculation is crowded with bacilli and well-filled phagocytes; but—and this is the important point—cultures made with the various internal organs prove absolutely sterile. The bacilli, therefore, are arrested at the point of inoculation by the amœboid cells, and this can be proved by microscopic examination.

Now if at the same time that we inoculate the bacillus pyocyaneus on one side of the body, we inject on the other side a large dose of chloral hydrate, which is yet not sufficient to cause death, and repeat the dose from time to time, so as to keep the animal fully anæsthetized, it invariably dies within forty-eight hours, and all the organs contain the bacilli in incredible numbers.

It is easy to prove that in an anæsthetized animal the leucocytes are inactive. Let us take two small sponges, fill them with a pure culture of the bacillus pyocyaneus, and place each under a guinea-pig's skin. One of these animals we leave as a control, whereas we inject the usual quantity of chloral hydrate under the skin of the other. Six hours afterwards, when we take out both sponges, we find the fluid in the sponge of the chloralized animal almost as clear as when it was introduced. A few leucocytes may be seen in it, ten or twenty at most in one cover-glass preparation, whilst the control sponge is filled with a thick purulent material, which, on microscopic examination proves to consist of innumerable well-laden phagocytes. No wonder, then, that when the leucocytes refuse their work the bacilli should find their way into the tissues. We have vainly sought for any evidence to show that the fluids of chloralized guinea-pigs are better cultivating media for the bacillus pyocyaneus than those of a non-chloralized animal; in both chloralized and non-chloralized animals the bacilli seemed to thrive exceeding well in the fluids of the living body. Here, then, we have another instance of the part taken by phagocytes in the limitation of the disease.

As to the substances which attract the amœboid cells towards the virus, they have been proved to be the poisons secreted by micro-organisms, or contained in their bodies. It is probable also that in some cases these poisons have the opposite effect, namely, that of repelling amœboid cells. I have lately gained considerable evidence to show that the same substance may attract or repel leucocytes according to its state of concentration. I may mention one such experiment. If a small piece of sterilized sponge be soaked in pure turpentine and placed under a guinea-pig's skin, it will be found that, even after a lapse of twelve hours, not a single amœboid cell has penetrated into the sponge. Sections made through the sponge and surrounding parts show that the amœboid cells have emigrated in considerable numbers into the tissues around, but they are arrested at a certain distance from the sponge, and can proceed no further. A piece of normal sponge placed a little distance off is absolutely crammed with amœboid cells, though the turpentine sponge contains none at all.

Now allow a similar sponge to soak in a very dilute solution of turpentine in olive oil, and place this sponge, together with another containing fine sterilized olive oil and a third soaked in pure turpentine, under the skin of a guinea-pig. After four hours the sponge in the solution of turpentine in olive oil is crammed with amœboid cells, whilst the other sponge soaked in olive oil contains but a few, and that in turpentine none at all. Hence, then, we have the same substance exhibiting totally different effects according to the concentration with which it is applied. It is very probable that such is the case with bacterial poisons also,

*These experiments will be related in full at some future date.

and there are already some experiments which support this view. Moreover, as Dr. Woodhead has already pointed out, the same substances which in the non-resistant animal repel amœboid cells, attract these same cells in considerable numbers when the animal has been artificially protected.

When once the poisons secreted by a particular kind of micro-organism have penetrated into the system, it would appear as if in many cases the leucocytes had lost the power of leaving the blood vessels in order to attack the invading micro-organisms. This loss of power is clearly not always due to a paralysis of the cells, as these still emigrate freely in order to attack certain other bacilli, but results from some other cause still shrouded in mystery.

I must refer to Dr. Klein's theory that the cells in the lymphoid tissues attract micro-organisms, and that "the bacteria find in the cells some attractive chemical substance which suits them, and hence these cells, far from being the enemies of the bacteria, are, on the contrary, their places of refuge for a time at any rate. This view seems to me just as feasible as Dr. Ruffer's views that because these cells contain bacteria therefore they are the chief and only bacteria-destroyers. Dr. Klein supports his views by two series of facts, namely, (1) that in a great many diseases the cells are destroyed by the bacteria, an objection which I have already answered; and, (2) that in a great many bacterial diseases the bacteria are found in the lymphoid tissues of certain organs.

In my lecture, previously referred to, I alluded to the fact that when the micro-organisms are inoculated into an animal, the amœboid cells are attracted to the point of inoculation, and that by Dr. Klein's theory it was difficult to account for this phenomenon. In his reply he states that I misunderstood him, and he referred to what takes place in the internal organs. I am sorry that I made this mistake, but nevertheless my argument loses none of its force; for clearly the phenomena at the point of inoculation must be first taken into consideration, and an explanation given which will reconcile Dr. Klein's theory with the phenomena observed. With regard to what takes place in the internal organs, the only evidence in favor of this theory is that micro-organisms are often found in cells. But I contend that this is not sufficient. Should anyone meet a dead lion and find a lamb inside, he, knowing the habits of the lion, would not conclude that the lamb had taken refuge in that. True, after a surfeit of lamb, the lion might die of indigestion, but the chances of the lamb ever getting out alive would be very small. Similarly, knowing the voracious habits of the lymphoid cells of internal organs, before we can accept this theory, observations must be made showing that the bacilli of their own accord force their way into the cells; explanations must also be found for the fact that the micro-organisms perish in the cells in enormous numbers; and lastly, he must explain why, according to Bardach, Sudakewitch, and others, animals normally resistant against a given microbe succumb almost invariably when the spleen is removed.

Remember also that phagocytes exert a distinct choice between two kinds of microbes. They will leave the bacillus of tetanus for the micro-bacillus prodigiosus, and the streptococcus for the bacillus of diphtheria. This is well illustrated in the diphtheritic membrane, where at the surface one can see leucocytes taking in numbers of bacilli, but leaving streptococci almost untouched; with the immediate result that streptococci are often met in the deeper parts of the membrane, and with the remote result that secondary abscesses occurring in the course of diphtheria are never due to the bacillus of diphtheria, but to some other micro-organism.

The study of the diphtheritic membrane shows the remarkable resisting powers of leucocytes, for although the tissues underlying the membrane are necrosed and dead, the leucocytes have the power of marching in their numbers right up to the bacilli and waging war against them, though many, as I have shown, perish in the fight.

Some investigators, the chief of whom is Dr. Buchner, of Munich, have laid great stress on the bactericidal action of the serum of resistant animals. I may perhaps be permitted to express my great admiration for Dr. Buchner's work, and that of his followers, and I am ready to allow that the facts as stated by Dr. Buchner, are in the main correct; but I am far from accepting the view that the fluids of the living animal play any part in the destruction of microbes in the organism.

In the first place, let us see what happens in animals which have undergone no protective treatment. If the bactericidal action of normal serum has anything whatever to do with the resistance of animals towards a particular kind of microbe, then whenever the resistance of an animal against a given microbe is great, the bactericidal action of its serum on that microbe should also be marked; and that when an animal is not re-

sistant, the bactericidal action of its serum should be feeble, or at least slighter than that of a more resistant animal. A rabbit is not resistant, and its serum possesses a strong bactericidal action on the anthrax bacillus; a dog is more resistant, and its serum has no bactericidal action on the anthrax bacillus. We have one exception, that is the white rat, which possesses considerable resistance against anthrax, and the serum of which has a strong bactericidal action on the bacillus anthracis *in vitro*. But this exception proves the rule, for when the bacillus anthracis is inoculated into a white rat, it thrives at first remarkably well, though it is ultimately destroyed by the animal's amœboid cells. That teaches us another thing also, namely, that it is impossible to argue that those phenomena which occur *in vitro* exclusively take place in the living body.

Were other examples necessary, I would draw attention to the fact that, *in vitro*, the serum of the non-resistant rabbit is a bad cultivating medium for the bacillus pyocyaneus, whereas the serum of the resistant guinea-pig is an excellent cultivating medium for the same bacillus. And conversely, I would point out that the serum of the resistant rabbit is an excellent cultivating medium for the bacillus of Chauveau, and that of the non-resistant guinea-pig a very bad medium for the same micro-organism. Moreover, I have proved that the fluids of both kinds of animals when alive form an excellent cultivating medium for this same bacillus. And yet another example of a similar nature. The bacillus of diphtheria in most animals is only found at the seat of inoculation, and in rabbits and guinea-pigs never spreads any further; and yet the serum of such animals is an excellent cultivating medium for the bacillus of diphtheria.

With regard to Sanarelli's experiments with the cell-free lymph obtained from the frog's lymphatic sac, I must acknowledge that such experiments are extremely interesting, and throw great credit on the scientist's ingenuity; but I contend that, from the point of view which interests us, they prove absolutely nothing.

This gentlemen placed particles of organs of an animal dead of anthrax in a small closed collodion bag, from 3 to 4 centimetres in length, and capable of holding about 1 cubic centimetre, and inserted the whole in the lymph sac of a frog. Three or four days afterward he removed this bag, and placed it under the skin of another frog; and then, after a like period, under the skin of a third frog. Examining its contents on the eighth or tenth day after its introduction into the lymph sac of the first animal, he found that no leucocytes had penetrated into the bag, but that the anthrax bacilli were mostly degenerated, and no longer capable of reproducing the disease when inoculated into a non-resistant animal. Now, it is almost impossible to introduce a bag measuring more than one inch under the skin of a small animal like a frog without producing not only serious lesions, but without grave risks of contamination also. In Sanarelli's paper there is nothing to show that the fluid bathing the outside of this bag was aseptic. Moreover, when we remember how leuco-cytes will force their way in a few days into such hard resistant objects as bone and ivory, it is difficult to believe that the inside of these thin collodion bags should have been free of leucocytes. But granting the fluid outside the bag was completely aseptic, and that no leucocytes had penetrated into the bag, I do not allow for one moment that the lymph contained therein was normal, such as that found in living animals.

The lymph during the last days of the experiment, was a mixture of three different kinds of lymph, collected during eight or ten days from three different frogs. Were any evidence necessary to show that this lymph was quite abnormal, I would point to Sanarelli's own paper, in which he says that the histological elements of the tissue introduced into the bag were so altered that they were perfectly unrecognizable. Would anyone maintain that normal lymph will destroy such a hard resisting element as the nucleus of a cell?

Interesting, therefore, as are Sanarelli's experiments, they prove nothing as to the bactericidal action of the normal lymph of a frog.

It has been proved experimentally that after an animal has been artificially protected against a given infectious disease, the serum of such an animal *in vitro* is a bad cultivating medium for the micro-organism causing the malady, and by some this has been set down as a general rule. This is not so however, for the serum of animals artificially protected against the bacillus of diphtheria possesses no bactericidal action on the bacillus of that disease, and the same remark holds good for tetanus. As I was writing this paper I received a copy of a paper by Mossig, in which he states that the serum of rabbits artificially protected against the pneumococcus is a far better cultivating medium for the pneumococcus than the serum of a normal animal. This bacter-

icidal power of serum is therefore not an essential corollary of the increased resistance of artificially protected animals. Moreover, our knowledge of it is at present extremely unsatisfactory, for there is no evidence to show whether it be a specific power of the serum on the micro-organism producing the disease, and on that micro-organism only; and we have no knowledge as to how long the serum of the animal retains this bactericidal power. I have very strong reasons for thinking that it is only of a very transitory nature, passing off long before the animal has lost its increased resistance.

However that may be, see what happens when an animal is inoculated with a micro-organism on which its serum exerts its bactericidal action *in vitro*. For I repeat it, what we want to know is not what happens when a micro-organism is introduced into the test tube together with that wholly artificial substance called serum, but the point is, what happens when it is introduced into the living tissues and blood of an artificially protected animal. I may perhaps be pardoned if I again refer to a series of experiments which Dr. J. H. Walker and I made on guinea-pigs, the resistance of which had been strengthened by a previous inoculation of the bacillus pyocyaneus. We chose this bacillus because my friends MM. Charrin and Roger have shown that the blood of animals artificially protected against this micro-organism possesses strong bactericidal powers.

The guinea-pigs, which naturally possessed a high degree of resistance against this bacillus, had been further protected by an inoculation of 0.25 cubic centimetre or 0.50 cubic centimetre of a virulent culture of bacillus pyocyaneus, and at the time we used them for our experiments they were perfectly recovered and proved to be efficiently protected against this bacillus. The skin of the animals was carefully shaved and two drops of a bouillon culture were injected under the skin. This dose does not produce the slightest symptom in protected animals. The first guinea-pig was killed by chloroform *20 minutes* after the operation, and curve-glass preparations were made from the seat of the puncture and stained with Loeffler's blue. In each slide several leucocytes were found already crammed with bacilli, while a great many micro-organisms were floating in the exudation fluid, and showed not the slightest sign of degeneration. Cultures made from the point of inoculation gave an abundant crop of perfectly healthy and normal bacilli.

Another animal was killed after two hours. Here the leucocytes were already in far greater numbers and contained numerous bacilli. The micro-organisms floating free in the exudation fluid were absolutely normal, and grew abundantly on agar, gelatine and bouillon.

Another guinea-pig was examined after six hours, and the point of inoculation was full of multinucleated amœboid cells, every one of which was crammed with bacilli. A large number of organisms were still free, and consisted of short, straight, and extremely motile organisms which grew abundantly on various cultivating media.

The fourth guinea-pig was killed after ten hours, and presented much the same appearance as the last; whilst in one killed twenty-four hours after the inoculation the leucocytes had emigrated in incredible numbers and the number of bacilli floating freely in the exudation liquid had correspondingly decreased, although such of them as remained free were marvellously active. A culture was mode from the point of inoculation, and this proved to contain nothing but bacillus pyocyaneus.

Although the bacilli had remained for twenty-four hours in the living fluids of this doubly-resistant guinea-pig it was impossible to detect the slightest sign that the fluids of the living animal had exerted their vaunted bactericidal action. On the contrary, they proved excellent cultivating media for the organisms.

Further, we found that the cultures made with the bacillus pyocyaneus, which had lived for twenty-four hours under the skin of a guinea-pig proved excessively virulent; and in one case, of a rabbit artificially protected and inoculated straight into the veins, we found active and virulent bacilli eight days after the inoculation.

Some observers object to the use of filter paper for wrapping up the virus when the object in view is to study the bactericidal action of the fluids of living animals on the grounds that it may arrest some of the bactericidal constituents of the lymph. It is strange that these gentlemen should bring forward this argument, as they accept the evidence based on serum which has been filtered through a porcelain filter, and it has been the boast of some observers that the bactericidal action could not possibly be due to the cells contained in it, as the bactericidal action was not abolished by passing through porcelain. In fact, these gentlemen strain at the gnat but willingly swallow the camel. As a matter of fact, however, I showed that leucocytes in few hours had made their way through the

filter paper into the interior of the bags, and it is clearly impossible to suppose that the same paper which is unable to arrest leucocytes should prove an effectual barrier to a chemical substance.

The increase of virulence in the tissues of artificially protected animals is a result which might have been foretold; for, if any micro-organisms survive at all in such animals, they must be those which, from some cause or other, possess qualities enabling them to resist the attacks of leucocytes, and to adapt themselves to their new medium. A short time after the inoculation, all the weaker micro-organisms must have been destroyed whilst only the stronger ones survived, and by this process of elimination a more hardy race of bacilli must have been obtained. And do we not see the virulence of anthrax increased by passing through resistant animals, such as dogs and pigeons, the bacillus Chauveau rendered more virulent by living in the subcutaneous tissues of resistant animals? But I will leave this point, as most probably Dr. Cartwright Wood will shortly have more to say on this subject, though I must again insist on the fact that in a large number of bacterial diseases, if not in all, there is no evidence to show that the fluids of a living resistant animal have the slightest attenuating action on the micro-organisms causing the disease.

I think there are few pathologists who will not readily confess to the feeling of intense astonishment which seized them when they first read Ogata and Jashara's paper, or rather the account of it as it appeared in the *Centralblatt f. Backteriologie.* Everyone had been trying to find a remedy against anthrax, and everyone had failed; and now it was sufficient to inject the minutest drop of a resistant animal's blood under the skin of another animal to cure it of anthrax. True, there were a few points in the experiment which did not appear quite clear, but still the evidence seemed fairly conclusive. Unfortunately, when other experimenters tried to reproduce these results they failed without an exception. But, for the sake of argument, we will suppose that Messrs. Ogata and Jasuhara's results are correct, and that for some reason or other the other experimenters were wrong. Granting all this, even then I do not see how Dr. Klein's contention holds good that the cure of anthrax in cases may be due to the antiseptic powers of the injected blood.

In the first place the quantity injected was infinitesimally small, and it was not always injected on the side where the virus was introduced but occasionally on the opposite side; so that this drop of dog's or frog's serum, before it had the opportunity of acting, was diluted in the whole of the blood of a mouse inoculated with anthrax. Moreover, when we come to see what is the action of dog's blood on anthrax bacilli, we find that it has only a very weak, if any, bactericidal power; so that, if Dr. Klein's opinion be correct, we must suppose that dog's blood, which has normally no bactericidal power, when injected into a mouse suddenly exerts —for reasons not explained—such a strong antiseptic action that it is able to kill millions of bacilli introduced into the mouse's system, although diluted in the whole of the animal's blood.

And what I have said of these experiments applies with even greater force to experiment made with the serum of animals artificially protected against tetanus, which possesses no bactericidal action on the bacillus of tetanus.

Of Mr. Hankin's experiments with the proteid he obtained from the spleen of white rats, I cannot speak from the chemical point of view, but one thing seems to me certain, namely, that this action of this proteid cannot be due to any bactericidal powers it may possess, for it is impossible to believe that a dose of albuminoid matter which has the power of killing a limited number only of spores *in vitro*, should be able to destroy the millions of bacilli inroduced into the excellent cultivating medium formed by the mouse's tissues and fluids. May I incidentally enter a protest against the crowd of new names with which Mr. Hankin has lately attempted to saddle our bacteriological vocabulary? To speak of alexines is scarcely scientific when their very existence is a matter of considerable doubt; but to talk of mycosozin or mycophylaxin when we have not the remotest idea what sozins or phylaxins are, or whether there are any such bodies, is hardly pardonable. Surely the first thing to do is not to give a hypothetical body a high-sounding name, but to isolate and study that body.

Truly the bactericidal properties of the serum of artificially protected animals are suggestive, and deserve to be studied, but I maintain that there is no causal relation between the bactericidal properties of the serum of a given animal against a given micro-organism and the acquired resistance against the same microbe.

One of the speakers has referred to the experiments of Behring, Kitasato, and others, in which the blood of an animal artificially protected against a given microbe possesses the

property of destroying the poisons of that microbe, not only *in vitro*, but also in the tissues of the living animal; and some have gone so far as to say that it was to this poison-destroying power of the serum that the increased resistance of such animals was due. Far be it from me to depreciate in any way the important results obtained by Messrs. Behring and Kitasato, but at the same time it is evident that this poison-destroying power of the blood is not a necessary accompaniment of the increased resistance of such animals. Thus fowls possess considerable resistance, not only against the bacillus of tetanus, but even against the poisons secreted by this bacillus; and yet the blood of fowls possesses no action whatever on the tetanus poisons. Let us turn now to animals artificially protected. Undoubtedly the serum of a rabbit protected against tetanus often possesses the power of destroying the tetanus poisons, but this is by no means *always* the case; and yet the rabbits, whose serum does not destroy the toxines, possess an increased resistance against the bacillus.

We must conclude, therefore, that, although in artificially-protected animals this property of the serum may be noticed, yet it may be absent even in protected animals, and is generally wanting in animals naturally resistant against tetanus; and also that the increased resistance of such animals is not primarily dependent on the poison-destroying power of the serum and tissues.

Another point which has been mentioned is that animals artificially protected against a living microbe can also to some extent resist the poisons of that microbe. Undoubtedly this is occasionally the case, but it is by no means a general rule, nor is this property of being able to resist poisons a necessary corollary of the increased resistance of animals artificially protected. Quite the reverse, in fact; for in some cases artificially-protected animals have less resistance towards the poisons than non-protected animals of the same species. It is occasionally possible to render animals insusceptible to the poisons of the vibrio Metschnikovi, but usually those animals which are already resistant against the vibrio succumb to the action of poisons more easily than non-resistant animals.

Similarly with the bacillus pyocyaneus. Some observers have occasionally been able to protect animals against the poisons of the bacillus pyocyaneus, but in most cases they have failed, although the animals had gained an increased power of resistance. I found, for instance, that by injecting small doses of sterilized cultures at varying intervals the animals invariably died, whilst a few small doses markedly increased their resistance. The conclusion to be drawn, therefore, is that the power of resisting bacterial poisons is not a necessary accompaniment of immunity, but may be present or absent without apparently influencing in any way the resistance of animals.

There is only one class of cells which appear to possess the power of quickly becoming accustomed to bacterial poisons, namely, the cells which are designated under the term of phagocytes. No doubt means will be found to increase the resistance of other cells of the body to bacterial poisons, and far be it from me to say that such an increased resistance and the poison-destroying power of the blood and tissues of the body do not play a part in reinforcing the resistance of animals; but I maintain that at first this property is not a necessary accompaniment of the increased resistance of animals.

It has been proved that the injections of bacterial poisons so influence the cells of the body that, long after their introduction, marked changes take place in the various organs of the body—changes which often prove fatal to the animals. But no doubt the converse is true, and in other cases the changes are of such a nature that they are of assistance to the cells in resisting the action of micro-organisms and their poisons. That is a notion which is as old as the notion of micro-organisms as essential factors in the production of disease.

There are many other points which I would have liked to touch upon, more especially the evidence on the so-called immunity produced by the blood of so-called immune animals. I must leave this for a future occasion, but I may state at once that these experiments, should they prove correct, are capable of quite another explanation than that given by their authors. And may I remind the Society that, more than two years ago, Dr. Charrin and I proved the presence of the poisons of the bacillus pyocyaneus in the urine of artificially-protected animals fourteen days after these poisons had been introduced; and also that we succeeded in rendering rabbits resistant by the injection of the blood of animals suffering from the pyocyanic disease?

The explanation we gave of this phenomenon was a good deal simpler than that now offered us; but we forgot to coin half-a dozen Græco-Latin words in connection with it, which circumstance may, perhaps, account for the fact that our discovery has fallen into oblivion.

In conclusion, it is my firm conviction that the only process which has been proved to be essential to the resistance of animals—whether this resistance be natural or obtained by artificial means—is the power that amœboid cells possess of taking into their interior and destroying micro-organisms, and there is overwhelming evidence to show that this process is proportional to the resistance of the animal. Finally, let me again repeat that neither Metschnikoff nor any of his pupils have ever said that this was the only cause of natural or artificial resistance.

MR. BALLANCE.

Mr. Ballance said that the question of immunity had an especial and weighty interest for surgeons, whose daily occupation was the making of wounds, which, if they were not rendered immune against the attacks of micro-organisms, might seriously imperil life. This immunity was attained as the direct outcome of the actions of the living cells and fluids of the neighborhood of the wound, The surgeon could only aid the natural processes by employing means calculated either to prevent the entrance of, or to destroy, or to inhibit the action of, these deleterious things which could thwart the struggle of the injured tissues towards the attainment of immunity. The healing of the body against the more generalized specific diseases was comparable with the processes employed by nature in the healing of wounds. The presence of pathogenic micro-organisms or their poisons in the body constituted, in one sense, really nothing more than the presence of a foreign body, which it was the function of the natural processes to get rid of. The observation, then, of the manner in which nature could absorb and remove foreign material in wounds would to some extent aid us in the study of similar processes when engaged in warfare against disease. He had been assisted by Professor Sherrington in studying the question of repair, and they introduced small Ziegler chambers into the subcutaneous tissue and peritoneal cavity of certain animals. In the chambers, in the tissue around the chambers, as well as in the normal tissue-plasma and normal peritoneal moisture, they found two distinct kinds of cells. The one kind resembled in all respects the leucocyte; the second kind was much larger, and possessed a large oval vesicular nucleus, which stained faintly, and the protoplasm of the cell body was markedly granular. Both these kinds of cells migrated into the chambers, but there was a definite sequence of events—the leucocytes commencing to enter the chamber shortly after it was implanted into the body, whilst the larger corpuscles (which sections of the inflamed tissue around showed to be the daughter cells of the surrounding connective-tissue corpuscles) did not commence to invade the chamber until some eighteen hours had passed. Briefly, the subsequent events observed were a loss of vitality of the small kind of cell and its inclusion in the vacuole of the larger kind. The larger kind, when all available food in the shape of fibrin and blood-corpuscle has disappeared, commenced to lengthen out and spin fibrous tissue. The less nutritious the more inert the foreign body, the sooner did the amœboid tissue cells become fixed.

They were greatly assisted in the interpretation of the appearances seen in the osmic fixed preparations by the processes described by Miss Greenwood in the Phizopoda. Just as in her interesting observations little monads coexisting in the same water as amœba proteus were by it ingested, so the leucocyte became the prey of the amœboid connective-tissue cell. In the chambers we observed giant cells formed by the fusion of connective-tissue cells, or by nuclear multiplication without actual separance of the daughter cells from the parent. These giant cell forms seemed especially to be present when the substance to be absorbed was more resistant than usual. We arrived, then, in this way at the conclusion that the invading leucocyte had only a temporary purpose to fulfil in the healing of a wound. The rush of leucocytes which occurred towards a spot invaded by micro-organisms might be thought of as useful in various ways:—(1) Though of feeble vitality, they might be able to digest and destroy certain of the foreign organisms; (2) by the death of others a ferment might be set free, which might diminish the vitality of some of the bacteria, and thus cause them to be an easier prey to other cells; and (3) abundance of food (in the shape of leucocytes) for the after-coming connective-tissue corpuscles would be associated with the attainment by them of the highest degree of vigor and vitality.

All the main work, then, in wounds, not only with regard to repair, but with reference to the removal of foreign bodies, such as clot, ligatures, micro-organisms, etc., fell upon the connective-tissues cell. Their observations gave no countenance to the old Cohnheim doctrine of the development of leucocytes into connective-cells. The legitimate succession of cells was now a well-established law in pathology, as well as in embryology, and, according to this, tissue was never produced by

substitution of function. No positive proof had yet been furnished that the elements of the blood took any active part in the restoration of lost parts. It did not appear reasonable or logical that such an indifferent cell as the leucocyte should ever become transformed directly into a fixed tissue cell, and it was still more improbable that it should be possessed with such a diverse vegetative capacity as to undergo a transition in one place into a connective-tissue cell, in another into the bone, and still another into muscular fibre. And if leucocytes in the healing of wounds had a subordinate function to fulfil, it was probable that they had a subordinate place in the fight against disease and in the attainment of a state of either natural or acquired immunity. In the formation of an abscess it was not the leucocytosis to the part which arrested the disease, but the wall of connective tissue formed around the infected spot by the aftercoming connective-tissue corpuscles. The speaker then discussed the question of the action tissue cells had upon substances outside themselves, and gave his reasons for believing that these cells furnished to the body fluids their bactericidal power. The death of leucocytes, which was always occurring, might be thought of as setting free into the body-fluids fibrin ferment, and fibrin ferment (if it existed) must be closely allied to Hankin's anti-toxic substance and Wooldridge's tissue fibrinogen. Clearly, whatever was in the fluids of the body must come from the cells. The normal physiological activity of the cells of the body might thus possibly explain the defensive action of the healthy tissues and fluids against bacterial infection. This clearly existed, for to produce disease a definite dose of micro-organisms must be administered. The normal quantity of anti-toxic substance present during any given period might perhaps correspond to the anti-toxic substance present in the food vacuoles *plus* the quantity secreted from the surface of the cells into the surrounding fluid. If, on the other hand, it were proved that living serum and plasma were not bactericidal, it followed that the anti-toxic substance was a weapon only used under conditions of irritation or emergency by the cell. It might be that an increase in the normal physiological activity of the cells, acquired as a habit, might explain, to some extent at least, some of the varieties of immunity. In conclusion, he desired to express the opinion that, however beautiful the researches might be that were conducted by the aid of the microscope alone in revealing more of the activity and life of cells, yet that in this way we should not progress far on the road towards a true knowledge of the intimate pathology of immunity. The problem of immunity was essentially a chemical one, and its solution must be sought in the laboratory of the chemist.

DR. E. H. HANKIN.

Dr. E. H. Hankin said that all previous speakers had taken one or other of the two sides of the question under discussion, but he believed that it was perfectly possible to take a middle course and combine the two opposite theories. There was a good deal of evidence to support the view that if an animal was naturally susceptible, very little phagocytosis occurred, and *vice versâ;* and on the other hand there was a certain amount of evidence that, after immunity had been acquired, the fluids of the body possessed bactericidal power. It was a pity that those who belonged to the school of solidists seemed to imagine that every additional piece of evidence bearing out the truth of the theory of phagocytes was of necessity evidence against the humoral theory, and similar reasoning had been adopted by those of the opposite camp. It appeared to him that the phagocyte theory was much like that put forward to explain the power of the magnet, and like it, though it was not the ultimate explanation, and did not contain the whole truth, had yet been of service, and had led to good results. He desired to discuss in a somewhat polemical way certain criticisms which had been made against his work. It had been asked if there was any evidence that elexin was a definite chemical body, or was it only a hypothetical body supposed to exist in fluids possessing bactericidal powers? He reminded them that elexins were probably proteids, and, like most proteids, were excessively difficult to obtain in a pure state. Many observers had shown that blood-serum possessed a certain power of killing bacteria, and that this substance existed in small quantity, and was probably allied to the fibrin ferment. Some time later Halliburton isolated a body which he called cell globulin β, and which he thought was identical with fibrin ferment. By putting two and two together the speaker came to the conclusion that the proteid of Halliburton was the bacteria killer, and he did his best to obtain this body in a state of purity. Dr. Wright had suggested that these elexins were identical with the tissue-fibrinogen of Wooldridge; but there was much evidence to produce against this view. They had, for instance, exactly opposite effects as to clotting, and he was prepared to give many other reasons as to his belief in the non-

identity of these two bodies. He then dealt at length with the criticisms of his work by the French investigators; they had repeated some of his experiments and obtained different results, but they had not used cultivations of the same virulence as his own. They regarded the death of the micro-organism not as due to its being poisoned by the chemical substances contained in the fluid, but rather to a change of the media. This he considered as tantamount to saying that if a man died of poisoning by arsenic he had succumbed to a change of diet. A baby rat's blood had no power of delaying disease or of preventing it; but yet it had just as great a power of attracting leucocytes to the seat of inoculation as that of an adult rat; this was because the blood of the latter contained a fluid of bactericidal power which was lacking in the former.

DR. SIMS WOODHEAD.

Dr. Sims Woodhead, in reply, drew attention to the word "immunity," which was used in two different senses in clinical and experimental work. A patient was only exposed to the ordinary chances of infection as usually understood, whereas an animal in the hands of the experimenter was subject to very different conditions, as for instance, when injected with an organism of specially virulent character. It was well known that under suitable conditions an organism might become much more virulent than usual. In the case of the tubercle bacillus, if it were injected into the peritoneal cavity of an animal, which was ordinarily insusceptible to the bacillus, tuberculosis could be produced with great certainty. He thought that specificity was to a great extent a question of phagocytosis; that, if an animal was immune, it was due to its phagocytic power. Professor Klein's case of injecting innumerable anthrax bacilli into the lymph-sac of a frog had no analogy, and, as Metschnikoff had stated, the phagocytic power of the leucocytes might in certain individuals be imperfectly developed. With regard to the main question, all the positive evidence was in favor of phagocytosis so far as the earlier stages of infective diseases were concerned, and it was the only theory on which both the experimental and clinical evidence could be explained. There was no real evidence for the humoral theory, and such would always be difficult to get. Results obtained with serum, which was a product of dead blood, could not be assumed to hold good for living blood. He quoted some experiments of Pflüger's, in which, after injection of peroxide of hydrogen into the blood of a living rabbit, no effect was produced so long as no blood escaped; but, if a single drop exuded, an evolution of gas occurred, not only in that drop, but throughout the blood of the animal. Again, freshly drawn pus had bactericidal properties which disappeared after the pus had stood for some time. These experiments showed how delicate was the substance with which we were dealing. Klein's fluid, obtained by dialysis through collodion from the lymph-sac of a frog ought not to be considered as exactly the same as the lymph from which it was drawn; yet results obtained with this fluid were taken as holding good for the fluids of the living animal so far as its bactericidal powers were concerned. He could not agree with Klein's statement, that bacilli got into the leucocytes to avoid the bactericidal blood-plasma, for many of them were non-motile, and could not possibly push their way into the leucocytes. If a paralyzed lamb disappeared in the neighborhood of a lion, it would be only fair to accuse the latter of some active part in the transaction. He firmly believed that the discussion, if it had not brought to light much new truth, would yet open up many new paths for investigation.

SIR GEORGE HUMPHREY.

Sir George Humphrey, having thanked those who had contributed to the discussion, congratulated England on its rising school of bacteriologists, who had accomplished so much, though having great disadvantages to contend against, owing to the false sentimentalism and prejudices against the true interests of humanity which existed in that country. Though he expressed himself as unable to sum up at all adequately the points of the discussion, yet he desired to offer the impressions the remarks of the speakers had made on his own mind. Zymotic diseases were dependent upon the introduction of micro-organisms into the system, and these microbes possessed the power of rapid propagation, and exerted a pernicious effect upon the organs of the body. They produced, moreover, certain excreta or toxines, which, even more than the microbes themselves, were prejudicial. The microbes and their toxines could not be dissociated; they both came in contact with the cells of the body, and with the body fluids. These body cells were undergoing continual change—change essential to their vitality, absorbing, modifying the material absorbed, and returning what was excreted into the fluids around. All body cells were phagocytes; that was an essential feature of their existence. But they were promiscuous feed-

ers, and would take up other things besides those normally supplied from the blood—they would absorb foreign matters—they would certainly absorb bacteria. Speaking technically, they were phagocytic as regarded the bacteria with which they came in contact, and there was abundant microscopical evidence of this, that they could exercise a solvent or destructive influence upon them. By far the majority maintained that the cells were an important element in the destruction of bacteria. Professor Burdon-Sanderson has found it difficult to conceive that there could be any special function in cells by which they could exert this malignant influence upon bacteria. But it was not necessary to assume that they were specially bactericidal; they were only phagocytic to bacteria by virtue of their general phagocytic qualities; it was a part of their general natural function, and not a special endowment. There was evidence that certain poisonous elements introduced into the blood did tend to attract leucocytes into their neighborhood. In some cases, the cells, so attracted, overpowered and destroyed the bacilli; while in the other cases they failed to do so, and the microbes spread over the system. In such instances cells might be found packed with microbes, the latter afflicting the former with such an indigestion as to cause their death.

On the whole, the general result of the discussion seemed to be in favor of the phagocytic action of leucocytes and other cells upon bacteria. A much more difficult question was the effect of the body fluids upon the bacilli and their toxines. In considering that we passed out of the range of ocular inspection and almost beyond the range of chemical examination, we had to deal with fluids of very peculiar composition and very great instability. It was found that the fluid serum in the test-tube might be fatal to a microorganism, and yet inject that microbe into an animal from which the serum was obtained, and it would flourish there; this showed with what delicate materials one had to deal. In this part of the discussion it seemed to him that the probability was in favor of the humoralistic view. But the fluids and the solids of the body interacted so intimately each upon the other that there could be no such thing as solidism and humoralism separately. Anything that could affect the blood serum must also produce an effect on the cells and the bacteria in it. The toxine of the bacteria diffused throughout the blood serum must exert some pernicious effect upon that serum as well as on the cells, and the serum so altered might finally react on the bacteria, and we must not assume that there was no effect because we could not demonstrate it. All the results he had spoken of so far have been obtained by experiment upon animals, but Dr. Bristowe had thrown some practical light upon the subject. He had remarked especially upon the resistance offered to the entrance of bacteria to the body, and referred to the probability that they became altered in their passage. When we considered the utterly inappreciable evidences there were to account for the degree of immunity possessed by different persons, we should not be surprised that it was surpassingly difficult to trace out the causes of immunity in different animals. He regarded it as almost hopeless to form an idea of the essential nature of the change which produced immunity from small-pox by vaccination. He regretted that the point of exhaustion had been rather summarily excluded from the debate. The manner in which a disease attacked one part, ceased there, and passed to another was difficult to explain on any view, phagocytic or other. The migration area in the course of a common cold was an instance in point. He referred to the phenomena in scarlatina, its incubation, its sudden accession, the sequence of phenomena to quiet subsidence, and, if not fatal, the immunity of the subject for a period. How was this explained by phagocytosis or any other theory? To what influence did the microbes succumb after having obtained a maximum of power? Was it because of some poison which they themselves engendered, or because they had exhausted the pabulum upon which they existed? It was difficult to explain the course of certain diseases of the skin by any theory of phagocytosis. We might rest assured that the interest in this subject had not yet passed away, for many of these problems were still invested with uncertainty, and that uncertainty was an invitation to work yet to be done.

MORTALITY OF DIPHTHERIA.

The comparative mortality of diphtheria in the principal countries of the world is as follows: England heads the list with only 41 deaths per 100,000 inhabitants. For the same number of inhabitants Belgiun had 44, Holland 53, Switzerland 59, Italy 79, France 80, Germany 100, Scandinavia and Russia 110, Spain 112, Austria-Hungary 116, and America 140. The statistics were collected by M. Janssens, the Chief of the Bureau of Medical Statistics of Brussels.—*Revue Médico-Pharmaceutique,* October, 31, 1891.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO. (Incorporated)

PROPRIETOR AND PUBLISHER.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.)

CHARLES K. MOUNT, Advertising Manager.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates),..... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts,.....$1.50 each.
Bovine Points or Quills,..... 1.00 a doz.
Humanized Crusts,..... 1.00 small.
Humanized Crusts,..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

☞Please accompany orders with the money, and address all communications to

LEADING ARTICLE.

THE RELATION BETWEEN EPILEPSY AND CHOREA.

Scarcely any other two diseases have been so extensively written about and theorized upon, with less discovery of absolute facts regarding them, than epilepsy and chorea. When all the mass of literature concerning them is sifted down, no more can be said than that their pathology is still a matter of uncertainty. Notwithstanding, it is of interest to realize exactly how far these two disorders can be compared, and if enough can be gleaned from our knowledge to connect them with the same causative conditions, something at least will have been gained. With this in view, Dr. G. P. Trowbridge, of the Danville (Pa.) State Hospital for the Insane, has made some careful clinical studies, and has recently published in a late issue of the *Alienist and Neurologist* a very interesting paper discussing at some length the relations which may exist between these two neuroses, as well as giving the results of a collective investigation among other asylums of cases which support the view that a very close relation does exist. Although for for many years the likeness existing between chorea and epilepsy in many of their features has been noticed, yet very little has been written concerning it, and for this reason we are indebted to Dr. Trowbridge for his interesting paper.

In the purposes of his paper, in order to compare cases of these neuroses in as pure a form as possible, Dr. Trowbridge confines his remarks to idiopathic examples of the two affections, excluding all those cases in which discoverable causes existed, although we cannot fully agree with him when he relegates all such cases to a category which he broadly terms "pseudo-forms of the disorders;" for it is in entire accord with our knowledge of these affections, that their real cause may be engendered by *very various* physical causes. Although, therefore, in our opinion, there is no reason why the discussion of the points of similarity between the two neuroses should not include all cases of either disease, no matter what the nature of their

causation, still, since the cardinal features of both are perhaps most strikingly apparent in the large class of unexplainable cases we call *idiopathic* or *essential*, we will confine these remarks to that variety of the two diseases. Clinically, we find the following points of similarity between chorea and epilepsy.

I. Both are markedly hereditary, and very often it is found that they affect the same families throughout several generations, and that choreic parents will have epileptic children.

II. Both diseases are characterized by convulsive movements of the muscular system,—in epilepsy this is periodic (but it sometimes continues for hours and even days), and in chorea it is a constant symptom except during sleep. The convulsions in both are undoubtedly due to interference with the stability of action of the nerve cell, causing them to discharge nerve-force irregularly.

III. They may coexist in the same patient, or a patient may first have chorea and have it cease only to mark the beginning of epilepsy, or epilepsy may usher in chorea.

IV. Both chorea and epilepsy affect the mind to some degree, and it is said by Warrington that the mental disturbances arising from them are very similar, so that it may be said that they produce nearly the same mental affections; and it will be admitted that these forms of insanity do not conform in type to other forms of ordinary insanity.

V. Both diseases are probably due to lesions of the brain only, and both are chronic disorders, or incline to become so.

The above are some of the points of likeness which chorea and epilepsy have in common. In support of the assertion that these diseases sometimes exist simultaneously in the same case, Trowbridge has collected seven such cases from American asylums for the insane, and fifteen cases which were affected with both diseases, but not at the same time. In seven of these fifteen cases chorea appeared first and was followed by epilepsy, and in only three cases did epilepsy appear before the development of chorea. In two cases chorea merged directly into epilepsy, while in the remaining cases an interval elapsed between the cessation of the one and the onset of the other.

Having glanced at one side of the question, let us look for a moment at the reverse side. Does *chorea of childhood* have any close relationship to hereditary epilepsy? If the affections were due to different degrees of the same pathological cause, should we not expect that their percentages of cures would be more nearly the same?

To the contrary we know that chorea of childhood in the large majority of cases runs a more or less definite course and that recovery is the rule and not the exception. Certainly very few rational signs point to any very close relationship between ordinary chorea of childhood and idiopathic epilepsy.

It is different, however, with hereditary chorea and chorea of adults without hereditary predisposition. These choreic manifestations are progressive, always attended by mental disturbance of some sort, and go from bad to worse until death terminates the picture of misery they present. No treatment influences their course or even alleviates the movements. It would seem, therefore, that between those choreic states of later life and chronic epilepsy there is a marked relationship, and that further study may unearth facts which will further prove the truth of this.

Many of the families affected with hereditary chorea have epilepsy very frequently in some branches of the genealogical tree, and sometimes it seems as if it had taken the place of chorea in one generation, which again reoccurred in the next; but too much importance cannot be laid upon this point for the same can be said of phthisis, which has been found to frequently exist to a remarkable degree in families subject to hereditary chorea.

This whole subject is one of purely speculative interest at present, and the most that can be said is that *chronic* forms of chorea present phases of causation, symptomatology, duration and termination which may justly make us consider whether the relationship between them and chronic idiopathic epilepsy is not more than a mere resemblance.

BOOK REVIEWS.

THE PRINCIPLES AND PRACTICE OF MEDICINE. By William Osler, M. D, New York. D. Appleton & Co., 1891.

The accuracy, clearness, and directness, the thoughtfulness and wide knowledge which have made Dr. William Osler's name so well-known to all serious students of medicine as a science, are as agreeably conspicuous in his latest book as in his many previous publications. A wholesome disregard for the "authority" which consists in the repetition of old commonplaces, and too easily accepted theories, is another familiar characteristic to be found in the present as in its author's former work—and the book will surely secure for itself a larger and more appreciative audience than the undergraduate or young students for whose use it is chiefly meant.

The arrangement of subjects is new and practical. First, specific infectious diseases—thirty-five diseases, including some described as doubtful (Well's disease, milk diseases, Malta fever, mountain fever, and sweating sickness), are included; constitutional diseases follow, then diseases of the digestive, respiratory and circulating systems, of the blood, of the kidneys, nervous system and muscles, the intoxications (obesity is construed as one of these), and last, those due to animal parasites.

It is impossible to undertake in a review to point out all the things which interest or strike the attention in a large book, whose subject is the whole science of medicine, but some detailed examination is both a pleasure and a duty here.

In the opening article on typhoid fever an excellent historical account of the progress of the differentiation of that disease from typhus and the other continued fevers is given, a result largely due to Louis and his American pupils, the Philadelphians Gerhard & Stillè, and George C. Shattuck, of Boston. The modes of infection are not considered at very great length, but an account of the instructive epidemic at Plymouth in 1885 is included. We turn to the treatment to find what the author has to say as to the newer methods. A moderate ground is taken as to the Brand treatment, though perhaps too much stress is laid upon the sufferings of patients from the cold bath. The statistics quoted are not strikingly in its favor: "expectant plan" mortality, 14.8 per cent.; incomplete bath treatment, 12.3 per cent.; strict bath treatment, 7 per cent." We had occasion several years since to examine the mortality of typhoid during a period of ten years (before the use of Brand's treatment) in two of the chief hospitals of Philadelphia. In neither did the mortality exceed 11 per cent.

For private practice Prof. Osler recommends in preference a lukewarm bath gradually cooled, or the cold pack, or repeated sponging. He pronounces antiseptic medication of no value. The routine administration of turpentine he thinks "is a useless practice for the perpetuation of which in this generation H. C. Wood is largely responsible."

In malarial fever Dr. Osler insists properly and very strongly on the absolute value of Laverou's hæmatozoa in the case of doubt in the diagnosis. "Not a single observer who has had the necessary training, has failed to demonstrate the existence of these parasites." Another means of attaining certainty, which anyone may apply, is "that an intermittent fever which resists quinine is not malaria." An illustration of the forms of the parasite and a note of the powers required in lenses for searching them would have been useful additions to this section.

As might have been expected, the book is strongest in its description of these affections where the nice observations, trained acuteness and painstaking minuteness of the diagnostician are most required. No such clear and simple presentation of the conditions, rational and objective, and the pathological anatomy of heart diseases, is known to us as is here made. One may occasionally criticise the refinements of pathological language as excessively technical. A student would make little of a statement that "a subvalvular stenosis, the result of endo-carditis in the mitro-sigmoidean sinus, usually occurs as the result of a fœtal endocarditis."

Another especially good chapter is on anæmia. The author nails his banner to the mast and stands for heroic doses of iron, Bland's pill for choice, and for quantity, say eighteen grains a day of the sulphate of iron, "one of the most brilliant instances of the specific action of a remedy." The section devoted to nervous diseases includes the most recently described forms of which modern refinement of diagnosis has added so many, and indeed the whole book is thoroughly up to date.

Dr. Osler is something of a nihilist therapeutically, and there are places where his laudable distrust of drugs carries him too far, but as a rule the treatment, which is

rather outlined than described, is on the whole sufficient. It is far better not to inculcate the sprouting M.D. with the idea that drugs are all powerful and must prevail. Let him have a wholesome distrust of their infallibility, and let him imitate Dr. Osler too in his accuracy and simplicity of thought and word, and in his hearty devotion to the highest and best work of his profession.

LITERARY NOTES.

THE WORLD'S COLUMBIAN EXPOSITION.

Bond & Co., 576 Rookery, Chicago, publish a four hundred page advance Guide to the Exposition, with elegant Engravings of the Grounds and Buildings, Portraits of its leading spirits, and a Map of the City of Chicago; all of the Rules governing the Exposition and Exhibitors, and all information which can be given out in advance of its opening. Also, other Engravings and printed information will be sent you as published. It will be a very valuable Book, and every person should secure a copy.—Price, 50 cents, post-paid.

SOME WAYS OF SERVING SWEETBREAD.

From Harper's Bazar.

Sweetbreads are daily becoming more and more in demand, both to tempt the capricious appetite of convalescing invalids, and for dainty dishes on dinner, lunch, or tea tables.

While by no means difficult to cook, care must be taken to follow the directions for their preparation, the process being the same no matter which of the recipes is chosen.

In selecting, the larger, plumper, and more fleshy they are, the better. Put them first into tepid water, letting them remain from fifteen minutes to half an hour, then set on the fire in cold water to which a little salt has been added. As soon as the water begins to boil, pour it off, and slip them into a pan of cold water until they are perfectly cold. This parboiling and chilling, which is termed *blanching*, makes them fair and white.

Next remove the pipe and skin. For this purpose scissors are better than a knife. (It is said that woman signalized her entrance into the chemist's laboratory by substituting the pitcher and scissors for the bottle and knife always used by man.) And as the sweetbreads are in pairs cut them apart.

Served Whole with White Sauce.—The sauce requires half a cup of milk, one tablespoonful of flour, and a piece of butter the size of an English walnut (allow the flour and the butter to each sweetbread). Braid the flour and the butter together, let the milk come to a boil, stir in the flour and the butter, add a blade of mace, and let all simmer five or ten minutes. The sweetbreads are simmered in this sauce until every tinge of pink disappears. They are kept in shape with the wooden toothpicks—called toothpick skewers—used for fish and small birds.

When thoroughly done, lay them on a dish, put a border of parsley around them, and pour the white sauce over and around them. The mace is, of course, removed before serving.

Sweetbreads with Cauliflower.—Cut the cauliflower into handsome pieces, blanch and trim the sweetbreads, and lay them all in a deep saucepan. Fill two-thirds of the depth of the pan with water, season with a few blades of mace, pepper, and salt. Let the whole stew for three-quarters of an hour.

To serve, place the sweetbreads in the centre of the dish, arrange the cauliflower in a border, and pour the gravy—thickened with cream and a tablespoonful of butter and flour rubbed together—over the sweetbreads.

Sweetbreads with Tomato.—Stew a quart of tomatoes until they are quite smooth—which will require about three-quarters of an hour—then rub them through a strainer so that you will have a smooth thick sauce. Have ready four sweetbreads, blanched and trimmed. Put them into a pan with the tomato, season with salt, pepper, and mace or nutmeg. Add two or three tablespoonfuls of butter rolled in flour. Set the pan over the fire, and stew until the sweetbreads are thoroughly done, which will be in about three-quarters of an hour. Before taking off, stir in the well-beaten yolks of two eggs. Serve with small pieces of fried bread placed in the dish with the sweetbreads, and the sauce poured over.

SAUERKRAUT IN DYSPEPSIA.

Dr. Heller, of Vienna, thinks he has found a remedy for dyspepsia in that well known digestive tonic, sauerkraut. It is especially recommended to nervous invalids who suffer from eructations and flatulence after meals. Dr. Heller is not trying to be funny, but apparently means what he says. That may do for the German stomach, but, perhaps, the American dyspeptic would do as well to stick to mince-pie and hot soda biscuits, with an occasional Welsh-rarebit thrown in.—*Med. Rec.*

PERISCOPE.

THERAPEUTICS.

CORN CURES.

Professor Whelpley gives some interesting facts in *Notes on New Remedies* about corn cures. The sale of plasters and other applications for corns is a large business, and all these preparations have as their active basis salicylic acid. It is combined with collodion and 9 to 48 parts, and painted over the corn; it is combined with rosin and balsam fir, with lanolin, 10 drachms of lanolin to 6 salicylic acid; with simple cerate, one of the acid to six of the cerate, and so on.

THE BROMIDES AND INCREASED SUSCEPTIBILITY TO INFECTION.

In the *Mercredi Médicale*, October 21, 1891, Dr. Féré takes up the assertion that patients undergoing bromide treatment are more susceptible to infection than others, particularly to the influence of Koch's bacillus. Upon this latter point there are no positive clinical evidences within the author's personal observation, yet during epidemics of pneumonia at the Bicêtre those persons under the influence of bromides proved most vulnerable. Animals inoculated with tuberculine virus after large doses of bromide began to lose ground immediately, and soon died.

ELECTROLYSIS OF THE CEREBRAL CORTEX IN THE TREATMENT OF JACKSONIAN EPILEPSY.

Dr. Negro (*Giornale della R. Accademia di Medicinia dix Torino*, Luglio-Agosto, 1891, p, 484) made a communication before the Academy of Medicine of Turin on this subject,

Among the operative procedures employed in the treatment of certain forms of partial epilepsy, the excision of portions of the cerebral cortex corresponding to the motor centres has been of late successfully performed. This method of excision offers several inconveniences, the principal of which are the following:

1. Injury to the neighboring cortical or subcortical regions, thus producing paralysis or paresis of muscles not in the realm of the Jacksonian epilepsy.

2. These operations are very bloody, and sometimes give rise to serious hæmorrhages.

The author proposes to substitute for the knife, electricity, to accomplish the excision of the brain cortex. He places a large electrode, the positive pole upon the sternum of the patient, whilst with the negative pole tipped with platinum, which he inserts at various depths into the diseased brain substance, he effects electrolysis.

A current of two to three milliamperes will in a very short time destroy the diseased brain tissue.

An operation performed by Dr. Carle with this method in a case of meningo-encephalitic gummosa succeeded in suppressing the epileptic phenomena.

SODIUM HYPOSULPHITE AS AN INTESTINAL DISINFECTANT.

Goll says, in the *Pharmaceutische Centralhalle*, that the abandonment of sodium hyposulphite in treating diseases of the stomach and intestines for other and newer remedies is a great mistake. In solutions, according to Goll, it is far more efficacious than resorcin, Carlsbad water, and salts, and, in fact, any and all the newer remedies used in the treatment of gastric and intestinal catarrh. Especially does it seem indicated in chronic catarrh, and its effects in this direction are very marked.

PROPHYLACTIC TREATMENT OF POST-GONORRHŒIC AZOÖSPERMIA.

Dr. L. Seligmann (*La Sémaine Medicale*, No. 51, 1891) advises to treat every case of epididymitis as soon as the acute stage is passed by methodical massage, inunctions with ichthyol salve and permanent compression. At each séance one should massage besides the testicle, the epididymis, and finally the spermatic cord as high up as possible; then rub the parts with a salve of ichthyol (5 to 100 per cent.) and place them in a rubber suspensory. By these means the nutrition of the testicle is improved as well as that of the epididymis and spermatic cord; the bands and deposits of hyperplastic connective tissue, which cause contraction and obliteration of the tubes and seminiferous vessels and subsequent azoöspermia, are caused to soften and disappear.

HYOSCIN IN THE INSANE.

Dr. Willerup (*Hospitals-Tidende*, R. 3, Bd. 9, p. 389) has used hyoscin in the Oringe Asylum. The dose varied from one-half to three milligrammes ($\frac{1}{120}$ to $\frac{1}{60}$ of a grain) two times a day, with a maximum dose of six milligrammes ($\frac{1}{10}$ of a grain), given by the mouth. He finds it of service in the chronic insane, where there is great restlessness. It is a violent poison, and its action unfortunately inconstant.

MEDICINE.

CEREBRAL ABSCESS.

Dr. Carl Lohmeyer reports (*Ber. klin. Wochenschr.*, No. 37, 1891) a case of abscess of the brain in which cure resulted from operative treatment. Patient was a man, aged 47. Up to the age of ten he had been healthy, but then had scarlet fever. No history of discharge from either ear at any time. Early in 1862 an abscess formed behind and above the right ear; it discharged itself spontaneously, and healed. Precisely the same thing occurred a year later, and when he came under treatment (April, 1889) a scar was found at the part which had been affected. In March, 1889, he suddenly felt a boring pain on the right side of the head. This persisted up to the date at which he came under observation, becoming worse in the evening. While at work he experienced giddiness to such an extent that he had to hold on to some fixed object. He could not stoop without becoming giddy, but was never so whilst sitting or lying down. No vomiting at any time of the disorder. Patient's state, when first examined, was as follows: He looked very pale and ill, his muscles were weak, and his body was wasted. He complained that his sleep was broken by pain and dreams, the former of a dull, boring, persistent nature, and localized, the exact seat being at the upper extremity of a line, 7 centimetres in length, drawn vertically upwards from Merkel's horizontal skull line (this passes between the outer angle of the eye and the upper edge of the tragus), 1½ centimetre in front of the maxillary joint and the vertical line of Merkel running upwards from that point. Pain was also experienced over the right side of the head generally, and radiated towards the right eye and shoulder. The eye felt as if it were being forced out of its socket. At the seat of greatest pain there was much sensitiveness to pressure and percussion. Neither the skin nor the bone at this part presented any abnormality. There was bony depression about the size of a finger-tip upon the right parietal bone 3 centimetres behind and 4 centimetres above the posterior and upper margin of the pinna, and 9 centimetres from the point of greatest pain. The external table and the diploë were absent at this spot. The skin over it was covered with hair and adherent to the bone beneath. The ears were examined with negative result; power of hearing was normal on each side. Pupils, optic discs, and movements of eye muscles normal. Tongue covered with thick fur; its movements normal. Mastication occasioned pain in the head, especially at the tender spot before mentioned. Swallowing was attended by difficulty as regards solids. Speech slow but clear. Heart and lungs not apparently affected. Temperature, morning, 37.4° C.; evening, 38.4° C. Abdominal viscera normal. During the day the patient remained sitting in an apathetic state, but was still able to undress himself and get into bed unassisted.

His condition remained unaltered for about one month, at the end of which time œdematous swelling and paralysis of left leg were observed. During the next month (May) the feeling of giddiness left him, but the pains in the head increased, and the loss of sleep became more marked. He passed less urine. Pulse, 54 per minute, temperature as before. On May 10th he complained of creeping sensations and numbness of the left hand, also of a feeling of heaviness in the left arm. On the 16th paralysis of the left arm was complete; both left limbs were now paralyzed. Pulse, 40, temperature, unaltered. Three days later ptosis was observed (side not stated). Power of vision in right eye now became impaired, and an early stage of optic neuritis was discovered there; left eye normal; pupils dilated; they reacted slowly, especially the right pupil. Patient grew more apathetic, and somnolence took the place of sleeplessness. Speech became indistinct, and answers inappropriate. He could now only swallow water. Early in June he became quite comatose. Pulse 38, temperature 34.4°.

The author assigns as a cause of the abscess in the brain, which was diagnosed from the above symptoms, the caries which had affected the upper and back part of the right parietal bone in 1862, and had produced the scar and bony depression before mentioned. The abscess must have originated in the upper part of the lobus paracentralis, or anterior and posterior central gyri, and have spread downwards and forwards, having its middle point about the middle of the anterior central gyrus. On June 12th an incision 6 centimetres long was made across the point of greatest pain, in a direction from above downwards and backwards. A portion of bone rather larger than a shilling was removed, whereupon the dura mater (which was normal and did not pulsate) protruded. This was incised, and the brain substance, with convolutions flattened and œdematous, brought into view and incised in its turn, whereupon greenish-yellow pus squirted out. Between 60 and 70 g. of this was obtained. The abscess cavity was then washed out with tepid boracic solution under gentle pressure,

and subsequently filled loosely with iodoform gauze. A bandage impregnated with sublimate was next applied. On the outer wall of the abscess was found a warty growth the size of a pea, composed of detritus. This, the author says, is to be regarded as the efficient cause of the abscess. After the operation the patient slept. There was a slight increase in pulse rate, but no rise in temperature during the next two days. On the third day he began to regain consciousness. On the fifth and sixth days the optic disc became normal, and the paralysis disappeared in the reverse order to that in which it set in. The patient was discharged about five weeks after the date of admission, there being still a slight flow of pus from the wound. In six weeks and a half the abscess was completely healed and the external wound closed. The man resumed work. At the date of report —five months after operation—he was well, and had in the meantime worked daily.—*Brit. Méd. Jour.*

SURGERY.

FRACTURES OF THE LARYNX.

In an article based upon experimental researches upon fractures of the cricoid cartilage (*Gaz, Hebd.* No. 42, 1891), Dr. Zilgien, of Nancy, states that an ossified cartilage requires considerably less force to sustain a fracture, than does a cartilage which has simply undergone amiantaceous degeneration. This degeneration of hyaline cartilage precedes ossification and calcification, and is characterized by fine striations in the hyaline substance. If the hyaline structure is intact the cartilage cannot be broken. It bends, owing to its irresistible elasticity due to its perfect homogeneity and the thick layer of perichondrium in which it is enveloped.

Experiments were made upon the exposed larynges of cadavers, by exercising slow pressure with the aid of a dynamometer and gradually increasing the pressure until fracture was produced. The pressure requisite to fracture the thyroid cartilage averaged 22 to 28 kilogrammes. The line of fracture was most frequently median when the cartilages were ossified or calcified, and extra-median when they had merely undergone amiantaceous degeneration. This degeneration was less marked in the median line than laterally. The pressure necessary to break the cricoid cartilage averaged from 16 to 18 kilogrammes. It usually broke on the anterior arch in three places—one median and two lateral; sometimes there was a median fracture only, sometimes a median and one lateral; rarely two lateral without median fracture.

The cricoid broke, therefore, at the same points as in the living subject. Pressure with the thumb at the median portion of the cartilage produced first depression of the anterior arch; then, if the cartilage was affected with amiantaceous degeneration, a fracture was produced at the point of junction of the anterior arch with the chaton of the cartilage about 6 millimetres in front of the crico-thyroid articulation. It is, therefore, an indirect fracture, occurring near the extremities of the great transverse diameter formed by the flattening of the cartilage, and it takes place at its most feeble point. At the same moment that the lateral fracture takes place, the anterior arch breaks at the median line. If, however, the cartilage is ossified or calcified, the median fracture is produced first. If the pressure is made along the axis which unites the two crico-thyroid articulations, the fractures occur at the same points, but the median fracture always occurs first. The fractures follow the direction of the amiantaceous striations parallel to the line of fracture. Hence they sometimes resemble the surfaces of diarthrodial articulations, excavated on one fragment with corresponding prominence on the other.

The mucous membrane is rarely torn, usually only contused. The inter-crico-thyroid membrane usually remains intact. The perichondrium is almost always torn in front, while the posterior perichondrium remains intact in the vicinity of the lateral fractures.

TREPANATION FOR EPILEPSY

Professor Studsgaard, of Copenhagen, reports three cases of this operation. In the first case, that of a man aged 27, who, when 12 years old, had been exposed to an injury of the head, nothing abnormal was found in the dura mater or the brain; the operation only improved the condition of the patient slightly. In the other case, that of a young girl aged 17, whose injury was contracted seven years previously, a detached, flat, small bone was found lying between the dura and the bone, and was removed; recovery followed. The third case is still under treatment; the patient, a man aged 24, exhibited a depressed cicatrix over the left eye. The epileptic fits were evidently caused by bony productions (osteophytes) of a depressed part of the frontal bone.—*Nordiski medicinsk Arkiv*, vol. i, No. 18, 1891.

OBSTETRICS.

ACUTE OOPHORITIS COMPLICATING PREGNANCY.

Dr. Coe, writing on this subject in the *American Gynecological Journal*, December, 1891, gives several instances of such complication and says: "In a patient with a history of previous acute oöphoritis and peri-oöphoritis, whether occurring before or during pregnancy, apprehension must be felt as to the possibility of a recurrence of the former inflammation after delivery. Labor should be conducted with rigid aseptic precautions, and with the least possible amount of interference; rough manipulation of the fundus uteri, as in expression of the placenta, is especially to be avoided."

CRANIECTOMY.

Prengrueber (*Sém. Méd.*, January 27, 1892) has successfully operated on a boy, aged 9, suffering from simple idiocy with microcephalus. The opening, eleven cm. in length by two cm wide, was made on the left side of the skull in the neighborhood of the left fronto-parietal suture. At this situation there was an exostosis both on the inner and external wall, the portion on the inside compressing the brain. Improvement was noted immediately after recovery from the anæsthetic, as his general appearance was better, his judgment increased, and his speech was more intelligible. On the next day the dribbling of saliva had ceased, and he was able to learn to blow his nose, a feat he had not accomplished before. He was soon able to play with his toys, and was much cleaner in his personal habits. Prengrueber considers that months and years must elapse before definite statements can be made in regard to permanent improvement.—*British Medical Journal*, February 6, 1892.

THE PUERPERIUM AS A FACTOR IN THE ÆTIOLOGY OF MULTIPLE NEURITIS AND DEGENERATION OF NERVE TISSUE.

H. Handford, M.D., in the *British Medical Journal*, Nov. 28, 1891, reports two cases of multiple nephritis, both probably of alcoholic origin, where the onset seemed most clearly to be determined by childbirth. He mentions a third case where the exact diagnosis was more difficult, but its onset immediately following confinement was equally clear. After quoting Grower's suggestion in this connection that "the tissue health is lowered, and hence slighter causes excite neuritis," he says the rapid progress of tabes dorsalis, and the frequency of optic atrophy in it when sexual relations are actively maintained, has been frequently noted. The relation of child-bearing is probably of a similar nature, and it is not suggested as a sufficient cause *per se*.

On the other hand, child-bearing is a common occurrence, and the neuritis may have been a coincidence, but multiple neuritis is a comparatively rare disease, and for three out of six or seven cases, in both sexes, to commence with childbirth seems an undue proportion. The author then asks, "Is the influence of childbirth one of the factors which render alcoholic neuritis so much more common in women than in men, while drinking habits are more prevalent in the latter?"

GYNÆCOLOGY.

SEPTICÆMIA FROM PUTRID FŒTUS.

Gendron (*Arch de Tocol, et de Gynec.*, October, 1891,) read a clinical report of two cases before the Obstetrical Society of Paris on October 8th. A woman had septicæmia close upon term, with high temperature and other grave symptoms. Labor set in, and when the os was half dilated, Gendron hastened the dilating process with his hand and extracted the decomposed fœtus. After rigorous antiseptic treatment during childbed, the patient recovered. A similar case was recently under his care. The cervix was rigid and dilatation imperfect. Gendron made an incision into the os posteriorly; then dilatation was easily completed and the putrid fœtus extracted. Recovery was perfect after the same treatment as in the first case.—*Brit. Med. Jour.*

HYDATIDIFORM MOLE.

Lwow (*Centralb f. Gynak.*, No. 1, 1892) has had four molar pregnancies under his own observation. The most evident of the predisposing causes is hyperplastic endometritis. There was no evidence of syphilis in any of the cases. All four had previously been under his care for uterine disease—endometritis, retroflexion, dysmenorrhœa, etc. Three were multiparæ, the fourth was a primipara. In all, diagnosis of molar pregnancy was easy on account of the unusually rapid increase of size of the uterus, and the free flooding; whilst in two cases the grape-like masses could be felt through the os uteri. In two cases the mole was spontaneously discharged. In the others it had to be removed with the hand, as repeated hæm-

orrhages threatened the patient's life. The entire mass could not be removed in one instance, as Lwow feared the uterine walls, as thin as paper, might be perforated by the finger. After the greater part of the mole had been taken away, the uterus contracted freely, and the remainder came away during convalescence. Lwow holds that warm irrigations, thrown up into the uterus, are perfectly justifiable after molar delivery. In all four cases they were employed, and proved satisfactory.—*Brit. Med. Jour.*

PELVIC INFLAMMATION IN WOMEN.

Dr. Potter, in a pathological study of this most interesting condition, which furnishes such a large proportion of the gynecologist's work, regards McMurtry's grouping of varieties of inflammation as about the best. It is as follows: 1. Inflammation of serous and cellular intra-pelvic tissues cannot be separarated clinically nor histologically, hence they cannot be properly distinguished by the terms perimetritis and parametritis. 2. The pelvic cellulitis of Emmet, which corresponds to the peri-uterine phlegmon of Nonat, is as rare as inflammation of the cellular tissue elsewhere. 3. Pelvic inflammation is, generally speaking, peritonitis resulting from disease of the ovaries or Fallopian tubes, or both. 4. Pelvic peritonitis presents every grade of activity, and is always symptomatic, never idiopathic. These inflammations are either of puerperal, gonorrhœal, or miscellaneous origin, and under the latter are included all infections of the endometrium by instruments, medicinal agents, and traumatism.—*American Gynecological Journal*.

PÆDIATRICS.

ZONA IN CHILDREN.

According to Comby (*La Bulletin Médical*, November, 22, 1891), the pathogenesis of herpes remains to be explained. He has studied the disease during eight years, and has collected thirty-three cases, twelve of which occurred in boys, and twenty-one in girls. The predominance of the disorder in the female sex has been observed by other authors. According to the statistics of Comby, the disease occurred in four children of less than two years of age; the ages of the rest of the cases varied from two to ten years. One of the patients was only eight months old. The affection did not present a contagious character, and it was more common in the spring and summer than in the months of autumn and winter. The symptoms are purely of an objective character, and it is worthy of note that, in children, herpes assumes a benign type. There is generally a slight febrile reaction, accompanied with gastric disturbance. The neuralgic pains are much less troublesome than in the case of adults. The author believes the disease to be essentially an infectious neuritis, and that the characteristic eruption is nothing more than a trophic manifestation which is proportionate to the extent of the lesion. Herpes may have also, however, a traumatic or other origin. The treatment is quite simple, and consists in the local application over the diseased parts of antiseptic remedies.

TREATMENT OF DIPHTHERIA BY IRRIGATIONS OF SALICYLIC ACID.

Parisot highly recommends (*Bull. Gén. de Thérap.*) the employment of irrigations of salicylic acid (1 to 1000) in diphtheria, as proposed originally by Weise and others, and affirm that whereas, before resorting to this method of treatment, the mortality from that disease as occurring in his practice was large—ten cases out of every fourteen— in a recent epidemic in which he had relied on the irrigations, there were only five fatal cases out of every twenty-four. He makes the solution by dissolving 1 part of the acid in twenty parts of alcohol, and then adding 980 parts of water. The apparatus which he used for the irrigation was simply a fountain syringe, the rubber tubing ending in a small glass tube. The head of the child is held by an assistant, the tongue depressed, and the jet directed into the mouth and posterior pharynx with sufficient force to detach and remove the false membranes if they happen to be loose. The quantity used must depend on the judgment of the operator. The irrigation does not wholly replace other remedial measures, such as the frequent administration of stimulants. Parisot makes some remarks as to the action of salicylic on false membranes which, if true, are of great practical importance. He believes he ascertained by experiment that this acid is destructive to diphtheric formations; in distilled water the false membrane was simply disaggregated, and this disaggregation took place slowly, while in solutions of different strengths of salicylic acid the exudate disappeared rapidly; at the end of a few minutes nothing was found but the meshes of the network serving for support to the cells of the exudation. The stronger the solution of salicylic acid the more prompt and complete was the disappearance of the exudate.

HYGIENE.

"L'ESTOMAC ET LE CORSET."

Dr. Chapotot, in a recent essay published by Baillière under this title, gives a fair summary of the opinions of experts such as Bouvier, Dickinson, Sibson, and others, on the real and imaginary evils attributed to constriction of the waist. The question of the true position of the stomach is very important in respect to the correct interpretation of abnormal relations of the abdominal viscera detected after death. The most original portion of Dr. Chapatot's essay refers to a matter of some interest to ladies. Young women have often reason to complain of disagreeable noises caused by air moving about in the epigastric region. Our author attributes these noises, which differ from borborygmi, to a vertical bilobulation of the stomach caused by the pressure of stays. During expiration the upper lobe is relieved of pressure by the ascent of the diaphragm. The lower lobe is, on the other hand, subjected to great pressure from the abdominal muscles. Hence air and liquids are forced upwards into the upper lobe through the narrow isthmus produced by the pressure of the stays; as they pass through the isthmus and issue out of it the characteristic gurgling sound is produced. If the stays be taken off, the sounds are no longer heard, but they may be reproduced by applying any other form of constriction to the abdomen at the same level.—*Brit. Med. Jour.*

A CHEAP DISINFECTANT.

At this season of the year and during the summer and autumnal months, disinfectants should be kept ready at hand for needed use, but not in any measure to take the place of cleanliness.

The nitrate of lead is the cheapest disinfectant known that fulfils its intent. It does not, however, prevent putrefaction. The chloride of lead is much more effective in all directions. It is made by dissolving a small teaspoonful of nitrate of lead in a pint of boiling water; then dissolve two full teaspoonfuls of common salt in eight quarts of water. When both are thoroughly dissolved, pour the two mixtures together, and when the sediment has settled you have two gallons of clear fluid, which is the saturated solution of the chloride of lead. A pound of nitrate will make several barrels of the liquid. The nitrate of lead costs from eighteen to twenty-five cents a pound at retail.—*Monthly Bulletin.*

THE INFLUENCE OF INFUENZA ON THE DEATH-RATE OF 1890.

The report of the Registrar-General for 1890, relating to the births, marriages, and deaths in England and Wales during that year has just been issued. The birth-rate, which had shown a continuous decline since 1876, was the lowest recorded during any of the last fifty years, although the marriage-rate during the last four years has shown a steady increase, and was higher in 1890 than in any year since 1883. With regard to the deaths during the period under review, it appears that the standard of public health reached in recent years was not maintained during 1890. The death-rate, which had been 19.1, 18.1, and 18.2 per 1,000 persons living in the preceding three years, 1887-88-89, rose to 19.5 in 1890. It should be noted, nowever, that compared with other earlier years, this death-rate was still a low one; for in none of the ten years 1881-90 was the death-rate as high as 20.0 per 1,000, whereas in no year previous to 1881 was it ever so low. The increase in the rate of mortality in 1890 is attributable to the epidemic of influenza, to which, although it was generally prevalent only during the first quarter of the year, 4,523 deaths were directly ascribed. This, however, probably represents but a small proportion of the mortality really attributable to influenza; for the immense increase in the mortality from respiratory diseases at the same time, notwithstanding the mildness of the season, was clearly due to the same cause. The Registrar-General estimates that the number of deaths directly or indirectly due to epidemic influenza in 1890 at upwards of 27,000, which is equivalent to a death-rate of almost one per 1,000. It is satisfactory to note that the mortality from nearly all other zymotic diseases was below the average. Only 16 deaths resulted from small-pox in 1890, the smallest number in any year on record. The deaths referred to constitutional diseases, especially to phthisis, showed a marked increase, probably attributable to the fact that a number of persons of phthisical constitution were prematurely carried off by the influenza epidemic during the earlier part of the year.—*Brit. Med. Jour.*

ANOTHER REMEDY FOR WHOOPING-COUGH.

M. Chibert declares that he has rapidly stopped the kinks of whooping-cough by sprinkling finely powdered iodoform on the child's pillow—*Répertoire de Pharmacie*, No. 8, 1891.

MEDICAL CHEMISTRY.

TESTING LARD.

The following method for detecting vegetable oils in lard is suggested by Welmans:

Dissolve the lard in chloroform, and shake the liquid with a solution of sodium molybdate in nitric acid. If the lard is pure the color of the mixture remains unchanged, while if vegetable oils are present the molybdic solution is reduced and assumes a green color, which is the more intense the more of the vegetable oil is present. On supersaturating this liquid with ammonia the green color changes to blue, while with pure lard no color is developed even after the addition of the ammonia.—*Zeitsch. f. angew. Chem.*

METHYL BLUE AND METHYLENE BLUE.

Both of the substances mentioned in the title have been introduced into medicine, but we have reason to know that the two substances are not only constantly confounded by wholesale druggists and dispensing pharmacists, but that the impure commercial articles are still kept in stock by many and dispensed.

Methyl blue has been recommended as an antiseptic in diphtheria and certain other diseases. Dr. H. Beyer (of Staten Island), in a paper published in the *Medical News*, first proposed it for this purpose, and recommended to apply it in form of a mixture containing 2 parts of methyl blue and 98 parts of powdered sugar.

Methylene blue is given internally, in doses of about 3 grains (in pills or capsules), in rheumatism of the joints and muscles; also as an analgesic, administered hypodermically in doses of $\frac{1}{10}$ to 3 grains; and has recently been lauded as an antimalarial remedy in doses of $1\frac{1}{2}$ grains, the daily doses not to exceed 10 grains.

Methyl Blue is the sodium salt of triphenyl-pararosaniline-sulphonic acid. It is also known as Methylblue M B I for cotton, and in German also under other names. It constitutes a dark-blue powder, soluble in water, forming a blue solution. The latter is not altered by hydrochloric acid. Addition of soda renders the solution reddish brown. In concentrated sulphuric acid, methyl blue dissolves with a reddish-blue color, which turns to blue upon dilution with water.

Methylene Blue, also known as Æthylenblau, Methyleneblue D B B, is a salt of tetramethylthionine (a body classed with the so-called thiazines, which are sulphurated derivatives of the aniline series). The most usual salt met with in the market is the double chloride of *zinc* and tetramethylthionine. According to Schultz (*Chemie des Steinkohlentheers*, 2, 762), the simple hydrochlorate of the base is also put on the market under the name of methylene blue. But we have so far not encountred the latter, all the samples which have come under our notice being the *zinc* salt, leaving on combustion about 10 per cent. of zinc oxide. It is possible that a zinc-free methylene blue is now on the market, but, as we have not had any occasion to examine the article for some months, we cannot be sure. At all events, it behooves those who use methylene blue internally to know whether they are given a zinc salt or not. Hence every fresh supply should be examined for zinc, which is easily accomplished by igniting a small weighed quantity in a crucible (which may be much facilitated by moistening the carbonized and cooled mass occasionally with a little water and nitric acid) until all signs of carbon have been burned off. The residue, if consisting of zinc oxide, will give the appropriate reactions.

We are unable to say whether the first proposers of methylene blue as an internal remedy were aware of the presence of zinc in the commercial article, or whether they used a zinc-free product. At all events, we are aware that many physicians who used the substance in this country employed the commercial article containing zinc. The question is now, What difference in therapeutic action is there between the two products, that comtaining zinc and that free from it? And did the beneficial effects of the remedy depend on the organic coloring matter exclusively, or on its combination with zinc? This is a problem to be solved by the pharmacologists.

HŒMOL AND HŒMOGALLOL.

There are two preparations containing iron, which for assimilation far surpass any compound previously used; they were first prepared by Prof. Kobert by the action of reducing agents upon the blood-coloring matter; in the first-mentioned zinc-dust is used (a minute quantity of zinc is allowed to remain in this preparation as it exerts a favorable action in certain defects of the stomach and intestines): in the last mentioned, pyrogallol is used; the former is a dark brown, the latter a red brown powder. The dose ranges from 0.1–0.5 gm. three times a day; an agreeable form of administration was found in chocolate tablets, each representing

a little over one milligram metallic iron, one to be taken fifteen minutes before meals. Patents have been applied for, for these two preparations.—*Oesterr. Ztschr. f. Pharm.*, 1891, 724.

NEWS AND MISCELLANY.

DANGEROUS PETS.

A French scientist declares that the domestic pets of the world carry at least thirty per cent. of the common contagious diseases from house to house.

One of our trained nurses sent to a physician of her acquaintance, of this city, under whom she had served, for a motto for her calendar. He sent her the following improvisation:

Instil hope,
Don't mope,
Use Soap,
So you'll best with evil cope.

THE DEBATE ON PHAGOCYTOSIS.

The debate at the Pathological Society came to a close on Tuesday last, having thus occupied three evenings. It has certainly been of great value, and it says much for the skill with which it has been conducted that the interest in a subject which involves of necessity points and arguments that are not easily grasped by the uninitiated should have been so well maintained. The paper with which Dr. Ruffer opened lasts Tuesday's proceedings was well worthy of the subject, and of one who is entitled to be regarded as perhaps the foremost student of phagocytosis in this country. It seemed to leave no debatable point untouched, and dealt in masterly fashion with the criticisms of Dr. Klein and the alternative hypothesis of Buchner and his followers. One great merit of this paper was the care with which its author avoided using the somewhat equivocal phraseology that has sprung up around this subject. There is no such thing, he boldly said, as "immunity" in the absolute sense, and throughout he preferred to speak of animals as being "naturally resistant" or "artifically protected," instead of using the hyperbolic terms that have become current. Phagocytosis, he maintained, is the only process which has been proved to be essential in the production of this resistance or protection, although "neither Metschnikoff nor any of his pupils has ever said that this was the *only* cause of natural or artificial resistance." Mr. Ballance's lucid exposition of the active part played by the fixed tissue cells in inflammation and repair and the subordinate *rôle* of leucocytes led up to the declaration that the former are probably the chief agents in phagocytosis; although the essentially chemical nature of the processes whereby immunity is secured was also pointed out. Mr. Hankin's interesting discovery of a proteid in the spleen of the white rat having bactericidal properties—although discounted by the supporters of the exclusive phagocytosis doctrine—undoubtedly gives strong support to the chemical theory of protection, and his speech was interesting as affording a reply to some of the arguments of Dr. Ruffer. In replying on the whole case, Dr. Sims Woodhead claimed that all the evidence hitherto adduced spoke in favor of phagocytosis being the agency at work in the living body, since the evidence on behalf of the humoralistic doctrine was derived from blood-serum or its products, which probably do not exist as such in the living animal. The summoning up of Sir George Humphry was weighty and judicial, and his tribute to English bacteriologists was felt to be well deserved. The debate will, we doubt not, go far towards opening up new paths of research in this extremely interesting question.—*Lancet.*

BAKER'S EMULSION

With Hypophosphites of Lime and Soda,

Among many points in which this preparation excels are:

1st—In the quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the ***Proportion of Oil*** it contains.

3d—In mode of manipulation and thorough incorporation, rendering it ***Permanent*** and ***Palatable,*** and of proper consistence, ***about that of Rich Cream.***

4th—***In Size of Bottles,*** containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

JOHN C. BAKER & CO., Philadelphia.

ESTABLISHED 1830.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

CLINICAL LECTURE.

MATRIMONIAL STERILITY.

By DR. L. SEELIGMANN,
HAMBURG, GERMANY.

Gentlemen:—English authors including Matthew Duncan, Sir Spencer Wells, Chas. West, and Marion Sims, of America, have shown by the statistics they have gathered that in England alone one marriage out of every eight is unfruitful. I have recently gathered similar statistics regarding the birth rate in Hamburg, and have found that out of 200 marriages among all clases 23 are unfruitful, which gives about the same proportion.

According to the researches of Kehrer, Duncan, Fürbringer, Noeggerath, Sänger, Prochownick, and others, the cause of this matrimonial barrenness must be laid at the door of the man in fully fifty per cent. of the cases, the main cause being the effects of past gonorrhœas and their complications.

The subject of matrimonial sterility may be divided into two classes:

1. Matrimonial sterility caused by the wife.
2. Matrimonial sterility caused by the husband.

The unfruitfulness of the wife can (according to Kisch's division) be due to the following causes:

1. Incapability of germ formation.
2. Hinderance to the contact of the normal spermatozoa with the ovule.
3. Incapability of incubating the ovule.

Apart from deformities and tumors of the female genitals, all pathological changes of the ovaries, tubes, the uterus and its ligaments and peritoneal covering, must be taken into consideration. All diseases of these parts can either act as a direct hinderance to fecundation, or by means of their action upon the nutrition of the genital organs give rise to an incapability for conception, or, finally, check the incubation of the already fecundated ovule.

Apart from tumors, which necessitate a surgical operation, or syphilis which calls for a specific cure, the advised therapy of the diseases leading to, or causing sterility on the part of the wife, has been most varied, comprising "cures" and "treatment" at various health or bathing resorts, mineral baths, especially hip-baths, cauterization of the cervical and uterine canal, and the use of the curette, etc. Recent researches have disclosed the fact that cauterizations, especially when undertaken with concentrated chemicals, accomplish an end precisely opposite to that which we desire to obtain—viz., a contraction and atrophy of the endometrium. Even the oft undertaken and apparently simple operations of division of a narrow os, and curretting, have been proved by their results, not to be the harmless operations as they have heretofore been regarded.

Recently two curative methods have been adopted by gynæcological therapeutics, which from their results may be regarded as the principal curative agents in female sterility. These are gynæcological massage in connection with gynæcological gymnastics as taught by Thure and Brandt, and gynæcological electrotherapy as taught by Apostoli.

It is highly possibly that we can by means of massage reduce the swelling and decrease the painfulness of ovaries which have been rendered thickened and painful by oöphoritis and perioöphoritis, and gradually render the organs capable of fulfilling their normal functions. It is unquestionable that we are able by means of massage to restore to its normal condition a tube which has been rendered incapable of performing its normal functions, viz., the free passage of the spermatozoa to the ovule by perimetric on salpingitic processes. Again, it has been abundantly proven that very frequently we can replace a uterus in its normal position after it has been retroflexed, bound down and apparently fixed by old parametric or perimetric adhesions, thus rendering the possibility of conception far more probable. At all events, we can at least by means of massage bring about a healthier and more

normal condition of the uterus and adnexa. By means of a methodically applied massage therapy we also find that old chronic catarrhs of the uterus are curable, as well as erosions of the os. Surely for the cure of endometritis such a mild and inoffensive treatment is preferable to the use of strong chemical reagents and the curette, especially when the cure of sterility is the desired result for which we are striving. This is especially evident when we take into consideration that the latter methods of treatment frequently give rise to an eventual stenosis of the uterine canal or atrophy of the mucous membranes.

In all cases of faulty or incomplete development of the female genitalia, in cases of uterus infantilis and small ovaries, massage in connection with electricity promises the best results, and will in all probability render conception possible.

It will be seen, therefore, that massage is not only valuable in primary sterility of the female, but also in acquired sterility induced by disease, and especially in that form spoken of by English authors as "one child sterility" in which the severity of a primary childbirth or abortion has left a diseased or abnormal condition of the ovaries, tubes and uterus.

Another important point is that massage, in connection with the ichthyol treatment so highly spoken of by Freund, will cause a disappearance of the pain experienced during coitus, so frequently observed in these cases. Therefore, apart from the general benefit obtained, massage, in rendering sexual intercourse painless and therefore desirable, will, according to Duncan, Sims and Kirch, prove a most important factor in the complicated chain of requirements leading to conception.

Gynæcological gymnastics, as taught by Thure Brandt, will prove a valuable auxiliary to massage in bringing about a normal condition of the generative organs.

As a proof of the value of massage in the treatment of acquired sterility, let me quote you the history of a case that came under my observation, and which I treated successfully with the assistance of Drs. von Englehardt and Lomer at this Polyclinic.

The woman in question was 39 years of age, and married. She had borne two children; the last having been born fifteen years previously, at which time her lying-in period had been very tedious and accompanied by a great deal of fever. She applied on the fourth of September, 1889, for treatment, and upon examination it was found that she was suffering from a fixed retroflexion of the uterus and endometritis. She was treated with massage only, and her condition became so improved that she soon ceased to visit the Polyclinic. Later she returned and the treatment was continued. In April, of 1891, she became pregnant, after a sterility of nearly eighteen years.

Gynæcological electrotherapy, as taught by Apostoli, will often complete the beneficial effects produced by massage. Both the faradic as well as the constant current find their application. For instance, when parametritis or perimetritis is a prominent symptom the faradic current should be used, but when we have hæmorrhage with profuse catarrh of the endometrium, the constant current should be used intra-uterine. I would strongly suggest that unless there is a strong indication to the contrary, the negative electrode only should be used intra-uterine in the treatment of sterility.

This for the following reasons: First, the negative electrode exerts a mildly cauterizing action; second, it exerts a basic reaction in the uterine cavity, in opposition to the acid reaction of the positive pole. Since it has been proven that a basic or a weakly alkaline reaction forms a good ground or soil for the movements of the spermatozoa, the use of the negative pole would seem eminently applicable in such cases, to which Chariere has called attention, in which the utero-vaginal secretion is acid in its reaction. The beneficial action of vaginal irrigations with a 5 per cent. solution of phosphate of soda, so highly recommended by Charriere, can be considerably augmented by an electric treatment with the negative electrode.

Matrimonial sterility caused by the husband may be due to the following causes:

1. Impotentia coëundi.
2. Aspermatism.
3. Azoospermia.

Of these three causes of male impotency, the comparatively rare condition of impotentia coëundi, and the almost equally rare condition of aspermatism, we may pass these by and proceed to a consideration of azoospermia as the most frequent cause for sterility, or rather impotency, in the male.

Azoospermia, or a change in the ejaculatory fluid in which both quantitatively and qualitatively the semen is apparently normal, but in which the most important element, the spermatozoa are absent, can be caused by the following:

1. Stoppage of the vasa deferentia in consequence of inflammation or traumatism.

2. Nutritive disturbances of both testicles:
(*a*) occurring after funiculitis, epididymitis, and duplex orchitis;
(*b*) from constitutional diseases, such as syphilis, tuberculosis, chronic alcoholism, diabetes mellitus, etc.;
(*c*) from varicocele, hydrocele, kryptorchismus.
3. Atrophy of the testicles:
(*a*) after sexual excesses;
(*b*) after long indulgence in onanism;
(*c*) after injury to certain parts of the brain, especially of the cerebellum.

The therapy of the azoospermia resulting from the majority of these diseases, namely those of a constitutional character, consists, naturally of a treatment of the general symptoms by well-known methods.

I will, therefore, restrict myself to a consideration of azoospermia as a result of duplex gonorrhœal epididymitis. Gosselin, in an article published in 1853, was the first to call attention to the influence of gonorrhœal epididymitis upon the generative potency of the male. The article then published was a most complete and exhaustive one. Gosselin's researches showed that an obliteration of the vasa deferentia at any part could result from inflammation whereby the product of the testicles would be retained from the seminal ejaculation; the latter, however, being largely composed of the secretion from the prostate and Cowper's glands. One will also usually find at the side of the testicles, and frequently enclosing the vasa deferentia, a swelling or hardening, called globus gonorrhoicus by Gosselin, which usually is at the point of constriction of the vasa deferentia.

There exists but very little literature other than this concerning the pathological anatomy of gonorrhœal epididymitis. The chapter devoted to this subject in the majority of text-books usually treats of the pathological condition found on the autopsy table, and years after the cessation of causative inflammation. So, whether these conditions as found are the results of the original inflammation, or occur eventually as a result of the long continued functional disturbance, is difficult to say.

The action of gonorrhœal inflammations upon the testicles, epididymis, and vas is differently accepted by various authors. Whereas, for example, Zeisse considers that the inflammation of either the testicles or epididymis is an entirely harmless complication of gonorrhœa, Noeggerath, on the contrary, views with the utmost pessimism the future prospects of potency after an attack of double gonorrhœal epididymitis, and Fürbringer has only lately said that it was his belief that a post-gonorrhœal inflammation of the testicles would eventually rob these organs of their function of producing spermatozoa.

Gosselin's opinion regarding the possibility of the constriction of the vas deferens becoming widened in the course of time, is in direct opposition to Fürbringer's views. For my part, I am of the belief that the pessimism of Fürbringer and Noeggerath in this direction goes somewhat too far, since a number of cases are known to almost every practitioner, in which after the patient has suffered from double epididymitis consecutive to gonorrhœa he has, nevertheless, been able to become subsequently the father of healthy children. Perchance the pessimism of the authors is due to the class of cases that have come under their experience, it being a curious fact that usually the most puzzling cases come to the notice of investigators.

As a result of extended clinical experiences, and pathological anatomical studies conducted at the old general hospital of this city, with the very kind assistance of Drs. Rast and Simmonds, I have been able to reach the following conclusions:

In gonorrhœal epididymitis with inflammation of the vas deferens and the epididymis we are also apparently dealing with a phlebitis and periphlebitis of the plexus pampiniformis, and also a lymphangitis of the lymphatics which are so extensive in these organs. The frequently observed occurrence of a continuation of the gonorrhœal process by an inflammation of the testicles, epididymis and vas deferens surely points to the probability that infection is carried to these parts by means of lymphatics, and the peri-vascular lymphatic spaces. Apart from this the hydrocele that nearly always exists in these cases, and the frequently stubborn varicocele of the plexus pampiniformis show that the vascular system is also greatly affected by the disease. In consequence of the inflammation of the vessels and inflammatory change that continues to exist, it is positive that the testicles cannot any longer receive the proper or requisite nutrition, and therefore are frequently not able to perform their normal functions. This becomes all the more positive when we remember how such a highly organized secretion as the human semen must be influenced by the nutritive condition of the organ which generates it. We see this frequently in syphilis, during the existence of which, as in cases of varicocele there exists an oligozoospermia, the seminal ejaculation containing but few

spermatozoa or if any these are perhaps with little or no vitality. While this does not point to an obliteration of the vasa deferentia it nevertheless confirms the theory of lack of nutrition of the testicles.

I would suggest that every case of gonorrhœal epididymitis, with a view to the possible development of azoospermia, should be treated as early as possible to a systematic local treatment with massage in connection with ichthyol and permanent compression. I believe that by such a course of treatment we are able to retain or restore the nutrition to these parts, and cause an absorption of the inflammatory products.

For internal medication ichthyol is perhaps preferable to the much lauded iodide of potash, since preparations of iodine exert a deleterious action upon the production of semen. The technique of the massage is most simple, and consists in kneading and rubbing movements with the finger tips of one hand. Naturally, the sensitiveness of the organ must be taken into consideration, and the masseur should at first be very gentle, beginning with the massage of the testicles, then the epididymis, and finally the vas deferens. The cauda of the epididymis should receive especial attention, since at this there is a sharp bend in the vas deferens, and it is here also that after inflammatory processes, large quantities of lymphatic connective tissues may be found.

Ichthyol in the form of a five to ten per cent. ointment, made up with lanolin as a base, should be liberally applied to the scrotum every other day. In order to obtain permanent compression I have designed a suspensory bandage the bag of which is made of some impermeable material, elastic at the sides. By padding this bag with a thin layer of cotton, a very firm and comfortable bandage is obtained.

By these means we are enabled not only to successfully treat recent, but frequently also old cases of gonorrhœal epididymitis.

HYPOSULPHITE OF SODA IN THE GRIPPE.

Dr. Ringk (*La Semaine médicale*, No. 59, 1891) asserts that the best remedy in the the treatment of the grippe is the hyposulphite of soda, which, at the end of twenty-four hours, will produce a rapid retrogression of the symptoms. He employs it as a potion in the following formula:

℞ Hyposulphite of soda.....grammes 4.
Distilled water..... " 100.
Raspberry syrup..... " 20.
A teaspoonful every one to three hours, according to the gravity of the case.

RELAPSED HIP-JOINT DISEASE—DIAGNOSIS OF SPONDYLITIS.

By H. AUGUSTUS WILSON, M.D.,

Professor of General and Orthopedic Surgery in the Philadelphia Polyclinic, Clinical Professor of Orthopedic Surgery in the Jefferson Medical College, Clinical Professor of Orthopedic Surgery in the Woman's Medical College.

Delivered in the Jefferson Medical College Hospital.

RELAPSED HIP-JOINT DISEASE.

Gentlemen:—I shall bring before you this morning a case that should impart to you some important lessons if you will observe the principle points in reference to it. His family history is tuberculous. His brother had a double hip-joint disease, and upon him an excision was performed at this hospital, and another somewhere else. This patient four years ago had on the left side a tubercular ostitis which was treated on the conservative principle of immobilization, and a year ago the inflammatory symptoms of the hip had entirely subsided with no symptom of abscess. The case was in a most happy condition and had every prospect of having a useful leg, although there existed some fibrous restrictions to free motion. While playing with some boys, he says, his left leg became twisted, the partial anchylosis was probably broken at that time, and serious inflammation immediately followed. The patient comes here this morning with an abscess of the hip-joint as a direct result of the recent traumatism, and in a condition of relapse. The question as to the method of procedure is important. If dead bone exists, it must be removed either by operation or by absorption of the inflammatory process. There can be no doubt that there is dead bone here; shall we then proceed to excise the dead bone at the same time that we evacuate the abscess? If we do so we shall expose the freshly incised surfaces which are now healthy to the action of the tubercle bacilli, and thereby tend to a still further dissemination. Hence it would be best to wash out the cavity and get it into a good condition first; subsequently we may excise the dead bone with a greater assurance of success. The operation to-day will be simply that of incision of the skin to evacuate the abscess, and subsequently we shall treat the cavity. Extending over the trochanter on the left side, as you may see, is a large swelling, a fluctuating mass, attended with a dusky redness of the surface. It is

undoubtedly an abscess having its origin in the hip-joint. For the purpose of drainage I shall make two incisions, one where the fluctuation is most pronounced, and the other at the lowermost point of the abscess. I find that over the great trochanter is the seat of the most fluctuation, and here I make my first incision. You can see the fountain of purulent material which is escaping. Now by means of a long probe I shall examine the condition of the abscess cavity. About midway down the thigh I can feel the end of the probe, showing that the pocket has extended beneath the fascia and reached this point, at which I shall make a counter-opening in order that I may institute satisfactory drainage. Now I must ascertain the extent of dead bone involvement by means of a small probe. I find at once a carious condition of the head of the femur and acetabulum, which is softened so that I can almost push the probe through the neck. Having now thoroughly washed out the entire cavity with peroxide of hydrogen, I inject ten per cent. emulsion of iodoform in olive oil, insert drainage tube, and apply aseptic dressing. The patient will be put to bed and maintained in the correct position to avoid motion, the abscess cavity again thoroughly cleansed to-morrow, and when the flow of pus has subsided, further exploration will be resorted to. In the mean time the affected hip will be kept at rest to avoid the breaking down of the already softened bone.

DIAGNOSIS OF SPONDYLITIS —ILLUSTRATIVE CASES.

This morning I want to present to you some illustrative cases which will show you how to make a diagnosis in Potts' disease or spondylitis. The cases I shall bring before you this morning will illustrate the case as well as the difficulty in diagnosing spondylitis, depending upon the age of the case and stage of the disease. Some of the cases carry their diagnosis in such a plain manner that you cannot fail to tell what they are. There is no credit to anyone in making such a diagnosis after the hump is developed, for it is impossible then to fail; the difficulty lies in recognizing the disease in its incipient stage. A curious feature of spondylitis is that all of the pain and all of the nervous symptoms are such as to draw the attention to some other part of the body rather than to the real site of the disease. This same curious feature is noticed occasionally in hip-joint disease, where the trouble is frequently referred to the knee-joint. When there is pain in spondylitis, it is apt to be referred to different portions of the body, as are also the nervous symptoms which are dependent upon the accompanying nervous disturbances. Then there is a dyspnœa associated with caries of the dorsal region. Also there may be an irritable condition of the bronchi or of the bladder, so that the disease will simulate a pneumonia, a bronchitis, or a cystitis, and, in fact, cases have come to my notice that have been treated for these conditions.

This little fellow carries his diagnosis with him in such a manner that it is unmistakable. The manner in which we left this child illustrates the care to be observed in lifting such cases. If we should lift him by the shoulders, we would allow the weight to hang upon the diseased portion of the vertebral column. As we lift the upper portion of the body, at the same time we raise the lower portion so as to disturb the existing relations about the focus of inflammation as little as possible.

The boy has a kyphosis involving the upper dorsal vertebræ due to tubercular caries. Just above the kyphosis is a bending in, which is a compensation to allow the weight of the child's head to be projected in as near as possible a straight line. The breast here is what is called "pigeon-breast," because it resembles the pointed angular condition found in pigeons and is due to the distortion of the ribs. As we examine the scapulæ, in addition we find they are both very prominent, the angles standing out in an unnatural position. The ribs have changed position, and hence the scapulæ are in this abnormal position. There is also a decided shortening of the trunk. If we were to take a curve of any kind, say one of whalebone, and straighten it out, the length of the curve would not be increased, but the distance between the ends of the curve would be greater when it was in a straight line. So here as the column curves the trunk becomes shortened. Below the diseased vertebræ the spine is straighter than the normal vertebral column. There is no trouble in this case in making our diagnosis, but the important thought is, was it possible to make the diagnosis in its incipiency. This is the question I want you to solve for me this morning. As to the diagnosis with reference to the situation, or what is called the localization of the spinal lesions, that is a subject which will require careful consideration with suitable cases after you have become more familiar with the gross manifestations of the disease.

This next little fellow presents the following symptoms: There is a disinclination to lift the head, which constantly rests against

the mother's shoulder, as you may see. As I put my hands upon my hips in the position called "the arms akimbo," I can lift the weight of my head from the spine by muscular effort in a mechanical way. This is a position assumed by children often in their instinctive efforts to lift or relieve the weight from the carious spine. In addition this child has the characteristic rasping, grunting respiration which makes it possible to diagnose caries of the spine before the kyphosis presents itself. If you will fix your ribs and diaphragm firmly by muscular action with the desire not to move them, and then try to breathe, you will have the sound produced which is almost pathognomonic of caries of the vertebræ. Another point that shows the same thing is the rigidity of the muscles, and this is an early symptom dependent upon the child's efforts to avoid motion. As I hold the child in a prone condition on my lap I do so to overcome any muscular rigidity. If I hold him up in the sitting posture I feel his desire to have me hold his head, and I feel also the rigidity of the muscles of the chest. If I ask a child with a supposed caries of the spine to stoop and pick up an object from the floor, he will not stood as a natural person will, curving his spine in the act, but will go through a manœuvre, that will keep the spine rigid, and go down sidewise by bending his knees and hips while feeling for the body with his hands. Another method, and one which is frequently preferred, is, the patient lying prone on a bed to take a child by the knees and raise the body gently sufficiently far to have the hips free from the table or bed. The spinal column instead of bending is held in a position of fixation and the curvature still shows itself in a slight degree. If I were to do this to the natural spine, the hips would arch up, and the arch would extend through the entire spinal column. The pain, when present, is generally present in the early hours of sleep, during the first two hours most markedly. This is due generally to the inflammatory exudate, and not to the pressure of bone upon nerve trunks or filaments, or it may be produced mechanically by muscular rigidity. The pain is seldom felt at the seat of the disease, but at some distance from the site of the caries. In this child it is possible by means of the fingers to follow up every spinal process above the seat of the disease; but at the site of the disease, the processes are all locked and massed together, while below they are distinct. Observe the rigidity and forced respiration in this girl which can be plainly seen by all of you in the motion of the ribs, even if you cannot hear the respiration. The mechanical explanation of this I have given by explaining the effect of rigid muscular contraction, but it is not the only explanation given. Another explanation is that it is due to compression of nerves supplying the respiratory muscles at some point in their course.

One of the best methods of making a diagnosis is by carefully noting the patient's own movements. If we ask him to turn over while lying down, he does so carefully to prevent jarring his back. The child invariably assumes a position which will relieve the body of the weight of the head. The bodies of the vertebræ are in a spongy condition and every movement produces a mechanical disturbance. As the child walks off you can see the rigidity which is characteristic of these cases. Later, when ossification has taken place, either in a deformed or straight position, this spinal rigidity remains but it is unassociated with muscular rigidity.

This man is a case which has gone through the regular routine of just such a caries of the spine. He will be of interest to us in the differential diagnoses of Potts' disease. As he stoops to one side there is a straight line up to the site of the disease without any natural curvature. On account of the position and extent of the deformity, it is impossible for the man to lie flat on his back. I want to show you what is to be guarded against in case of caries of the dorsal vertebræ. Psoas abscess is so called because it is an abscess formed in the sheath of the psoas muscle from the pus from a vertebral caries. If the disease is high up in the cervical region, it shows itself as a post-pharyngeal abscess. Lower down the pus follows the course of the psoas muscle, and may appear at various places, the most common being in the groin. By putting the legs in a flexed position on the body so as to relax the psoas muscle, you can push your fingers back so as to feel the pulsation of the abdominal aorta. If there was a swelling here or a mass which felt like a gelatinous tumor you would have evidence that there was a psoas abscess. I can pass my fingers back very far here, and I could not do that if an abscess were present. This man a few months ago had a very large abscess showing itself above the hip joint. Fluctuation was distinct on one side, and was communicated to a mass on the other side, proving the presence of a double psoas abscess. This abscess showed itself at the hip, and the patient was operated upon. You can see this long cicatrix over the hip. It

was a case for differential diagnosis at the time referred to, as to whether it was an abscess due to hip-joint disease, or was it a psoas abscess pointing in an unusual position. You will remember the boy that Professor Forbes operated upon had caries of the vertebræ, and also a hip-joint disease; so it is possible to have both conditions present co-existing in the same patient. The diagnosis was made in this case by examining the hip-joint in the manner familiar to you. There was no rigidity of the hip-joint; we could move it freely; there was no pain. Still further evidence of the correctness of our diagnosis was had at the time of the operation, which would have to be done in either case. A probe was passed up under the gluteal muscles to the lumbar region, and from there its course could not be definitely traced, although it appeared to go in the direction of the psoas muscle, showing it was not an abscess connected with a hip-joint disease. The case was drained, and gradually the sinus healed. Whether at the present time an abscess exists, I cannot say. There is no evidence of it, and I believe it has been entirely cured. It not infrequently occurs that, following an evacuation of such an abscess, resolution takes place by the absorption of any remaining cazeation, made possible by the relief of tension.

Other joints in the differential diagnosis of caries of the spine are these:—

First, in a child there are occasionally seen sprains of the spine due to falls. These sometimes also present history of pain in the stomach and legs, irritable bladder, dyspnœa, and rigidity. In these cases it is often impossible to make an accurate diagnosis at the first visit, but by careful watching you can arrive at a conclusion.

Treat such a case as possibly caries of the spine, and allow it to go on to recovery, which it will speedily do if only a sprain. Often there are cases of rachitic spines, but here we have the other evidences of rachitis; the enlarged distal extremities of the radius and ulna, and nodes elsewhere.

But most of all in these cases there is increased mobility of the spine, instead of the rigidity of caries of the spine. In rotary lateral curvature, I could hardly conceive how there could be any difficulty in diagnosing the disease from this condition. At times in Potts' disease there is at the upper portion of the body a lateral deviation, the so-called lateral deviation of Potts' disease. This, however, is entirely different from the deviation in rotary lateral curvature. There is in Potts' disease a distinct knuckle or angular curve, while in rotary lateral curvature there is a gradual bending.

In cases of hyperæsthetic, railway, or hysterical spine the spine is exquisitely sensitive. The slightest pressure causes intense pain. The method of making the diagnosis is by a study of the general condition. If there is a neurotic condition of the whole body, and the patient is a young girl at the age of puberty, you will be inclined to consider it is an hysterical spine and not caries. It is hardly worth while to enter into a study of the differential diagnosis between caries or abscess due to it, and typhlitis between hernia and psoas abscess showing itself at Poupart's ligament, or any of the other rare possibilities, because the occasions will seldom occur that will render such a diagnostic skill necessary.

At our next clinic I shall bring before you the various methods of applying mechanical restraint in the treatment of caries of the spine, and in the mean time will ask you to study the subject of the mechanical requirements as indicated to day.

SUPPURATIVE OTITIS AND CEREBRAL SYMPTOMS AFTER POSTERIOR TAMPONING FOR SEVERE EPISTAXIS.

Dr. Gellé, in speaking of the post-nasal tampon, says: The tampon both opposes the exit of blood which has already penetrated the tympanum, and facilitates the penetration of purulent secretions into an ear previously unaffected. In both cases tamponing is bad. The blood in the nostrils, pent-up, putrefies, being mixed with the microörganisms contained in the nares, and the inflammation is septic. Infectious otitis, or bilateral suppurative otitis, appears simultaneously and with the characters of gravity and rapidity of invasion common to the evolution of septic affections. If the obstacle be not removed in time, it is not the patient who will demand help—he may be in coma or delirium—and the diagnosis is made by the exit of infectious pus from one or both ears; or the patient may succumb to the propagation of the infection to the cranial cavity. [This terrible result is not rare; the author recorded a case in 1882, and has lately reported fresh instances.] Posterior tamponing is therefore, dangerous, not only to the ears, but to life itself. It is not a more or less badly made tampon, but the tamponing itself which is a bad proceeding, and the longer the tampon remains *in situ* the greater the danger.—*Journal of Laryngology, Rhinology and Etiology*, January, 1892.

COMMUNICATIONS.

LEPROSY.*

By W. H. DALY, M. D.,
PITTSBURGH.

Last March, through the courtesy of the experienced and efficient Harbor Physician, employed by the Marine Hospital Service of the United States, at Havana, Cuba, Dr. Burgess, I was enabled to examine nearly one hundred cases in the hospital for lepers, in Havana, and while I was more particularly interested in the phases and effects of the disease upon the structures, and functions, of the naso-pharynx and larynx, and other air passages, and also in the study of the fresh and recent cases, yet a general study of the disease made itself felt as one of unusual interest, since, with the great mass of busy practitioners of medicine, I had before that time only a vague idea of the clinical features of the disease, and had never in the whole course of my professional life examined carefully a case of leprosy. I would venture to say that probably 90 per cent. of the medical practitioners of the United States could neither describe the disease in many of its protean forms, or diagnosticate a recent case if they saw it for the first time.

The time has come when the National or State Legislators ought to take some adequate action to prevent the ingress of lepers to the United States, and also to forcibly isolate those already within our borders. It it therefore the duty of the profession to instruct the Legislators, and the public, upon this question. And it it a matter of congratulation to Pennsylvanians, that their State Board of Health had recently sent to the profession circulars making inquiries for the purpose of legislation, and it is to this end that I would give some views and observations briefly. But the profession could do little or nothing without the public, who are indebted to the unselfish recommendations of the medical profession for their light and life in matters of public health, by the recommendations of the latter for the stamping out of preventable diseases; hence the public ought to be informed as to the needs of the hour, and urged to act through their representatives.

An eminent dermatologist, and valued friend, Dr. L. Duncan Bulkley, of New York, had recently expressed doubts, before the New York Academy of Medicine, as to the contagiousness of leprosy, and Dr. Daly read the published paper with some apprehensions as to the effect of the expressions of so distinguished an authority upon the profession, and there were some statements made by the doctor that ought to receive further discussion.

Dr. Bulkley stated that English observers were positive that not a case of communication of the disease had ever taken place there (in England.) This upon reflection can scarcely be taken as an argument of any weight against the contagion, as great care has always been taken to isolate leprosy in the countries comprising Great Britain, and to that persistent isolation must in a great measure be attributed, not only the stamping out of the disease, but the prevention of contagion. Some light may be thrown upon the ancient habit of isolation, by quoting an historical authority, which says:—

*"The 'Mickle all,' or great disease, the leprosy, which the learned call tubercular elephantiasis, prevailed in nearly every district of Europe from the tenth to the sixteenth century.

"Scotland suffered from this hideous scourge as well as other countries. It was brought as some historians write from the East by those who returned from the crusades. But this cannot be, for there were leper hospitals in England before the crusades began. The disease lingered in the northern islands of Scotland long after it had disappeared from all other parts of Britain.

"The lepers appear to have been sent to the island of Papa."

The parish of Walls had lepers to support in Papa as late as the year 1740, as the books of the kirk-session show. In 1742 Walls held a day of public thanksgiving for the supposed final deliverance of the country from the leprosy. But there is little doubt that cases of true leprosy were to be found in Shetland up to the close of the last century.

When the leprosy seized its victim, the eye-brows and nostrils became swollen, and the countenance dusky and glossy, with a fixed look and an expression of terror. Livid pustules broke out on the face and body; the hair fell off; the voice grew hoarse and hollow. As the hideous disease advanced, ulcerating tubercles discharged a foul mat-

ter, dark scabs formed, and face looked the like a piece of rotten cork. A sense of weight and weakness oppressed the limbs. The fingers and toes mortified and fell off joint by joint. Corruption, by a frightful anticipation, began its work without waiting for the grave.

The large number of victims were no doubt found among the lower classes of society, the bondmen, the poorer tenantry, and the humble dwellers in the towns. But neither age, nor rank, nor sex was spared. The disease must have been very common in old Scotland, for every town was obliged by law to possess a leper hospital. Every hospital was bound by Papal "bull" to be provided with its own churchyard, chapel, and ecclesiastics. Saint Anne was the patron saint of the lepers, and a chapel dedicated to her was frequently connected with the hospital. The leper hotels were not intended as places for medical treatment of the disease, but merely for the separation of the diseased from the sound, lazarettos where the infected performed a life-long quarantine. They were for the most part founded and endowed as religious establishments, and were generally under the rule of some neighboring abbey or monastery. The inmates, doleful creatures, were expected to offer up daily prayers for the souls of the founder and his family. An order of Knighthood—the Knights of Saint Lazarus—was instituted about the time of David I. for the care of lepers. Knights of this order are said to have been common in Scotland and France. What kind or extent of power these knights were allowed to exercise over the lepers and leper houses is not known. Every person seized with leprosy within the walls of a town was removed at once to the hospital. If he had nothing of his own a collection of twenty shillings was made for his behoof. He who sheltered or concealed a leper even for a single night was heavily fined.

Some of the Scottish leper houses had large properties attached to them, and must have supported their inmates in all the comforts of which the unfortunates were capable. Others were but slenderly provided, and their miserable inhabitants were obliged to depend upon charity. The act of Parliament "anent Leper Folk," passed in the reign of James I. ordained that "no leper folk sit to beg, neither in kirk nor kirkyard, nor other place within the burghs, but at their own hospital, and at the gate of the town and other places outside of the burghs." They were allowed to enter towns for the purchase of necessaries only on Mondays, Wednesdays, and Fridays, from ten till two o'clock, on condition that they wore a cloth on their faces, and rang a hand-bell or "clapped to give warning of their presence.

The leper hospital at Greenside, Edinburg, was founded in the year of King James' marriage to Anne of Denmark. The money for the building was given by Jno. Robertson, merchant in Edinburgh, and others, in fulfilment of some vow. At the opening of the hospital five leper inhabitants were consigned to it. Two of the wives of these lepers voluntarily shut themselves up in the hospital with their husbands.

The rules of this hospital were probably more severe than those of other leper houses. The inmates were forbidden to go beyond the gate by day or night, work-day or holiday, on pain of death. At the gable of the hospital stood a gallows in perpetual readiness for hanging any leper who might venture forth. The rules of the house enjoined, "That the said persons and each one of them live quietly, and give no slander by banning, swearing, fighting, scolding, filthy speaking, or vicious living or any other way, under the pains to be enjoined by the (town) council. That there be appointed an ordinary reader to read the prayers every Sabbath to the said lepers, and a commodious place appointed to the said reader to that effect."

By this time, it would appear that the disease was on the wane, for in little more than sixty years after the opening of Greenside leper-house, the magistrates ordered its roof to be taken off, and the wood and slates to be used for repairing the town mills and other public buildings. The stones of the edifice itself, and of its garden wall, were applied to similar purposes.

A leper was held to be a man dead in law. He was incapable of inheriting, and lost all his civil privileges.

On the day that he was put into the hospital, the burial services were performed over him. A priest in surplice and stole went to the leper, and began the dismissal ceremony by exhorting him to suffer with patient and penitent spirit the incurable plague with which God had stricken him. He was then sprinkled with holy water, and conducted to the church, the usual funeral verses being chanted on the way. Arrived in the church, the ordinary dress of the leper was taken off. He was then wrapped in a funeral pall, and placed corpse-wise before the altar on two trestles, while the mass for the dead was sung over him. After this he was again sprinkled with holy water, and led to the hospital. A clapper and "cop," or bell and dish, a stick,

a cowl, and a leper's dress were given him. Before leaving him the priest solemnly interdicted him from appearing in public without his leper's garb—from entering inns, mills, churches and bake-houses—from touching children or giving them anything which he had touched—from washing his hands or anything that pertained to him in the common fountains or streams—from touching in the market the goods which he wished to buy with anything but his stick—from eating or drinking with any others except lepers—from walking in narrow paths—from answering those who spoke to him in the roads or streets, except in a whisper, that they may not be annoyed with his pestilent breath and infectious smell. Last of all, the priest closed the ceremony by casting a shovelful of earth on the leper's body."

By the foregoing it will be seen with what care lepers have always been isolated in Great Britain, and to what causes the presence of the disease and contagion are so rare.

Now, touching upon the case of the death of Father Damien from leprosy, while engaged among the lepers. Dr. Bulkley quotes the doubts of Dr. Rigg, of Trinidad, concerning the contagiousness, while he also expresses his own, yet he says in the course of his paper, Father Damien "may have imbibed the leprosy germ in water, food, or air," but he thought the probable source of the infection was through mosquito bites.

For all practical and hygienic purposes it is quite needless to differentiate between contagion and infection. Sufficient for either question if admitted, is segregation, and all other quarantine measures to stamp out the disease.

The *N. Y. Medical Record* says editorially in its issue of Jan. 23, 1892, "There are not many lepers in New York, but there are too many." It is needless to say that from Pittsburgh alone there are at least fifty persons who visit Havana, Cuba, during every winter, and from Pennsylvania there are probably 200. The laws concerning isolation of lepers in Havana are disgustingly and perilously lax. Many years ago there was a wealthy leper who died in Havana, and who endowed a hospital for these unfortunates. As a part of that hospital there is a spacious shrine, or church, where inmate lepers and outside citizens meet Sunday after Sunday to worship. True, the lepers are not generally allowed outside the iron gratings of the porch, but they sit inside in crowds, and traffic in the closest possible proximity, and talk at will with their friends and loungers on the spacious steps, through the iron bars. Little children in crowds play about them on the steps, and witness the public swimming of the horses in the surf in front of the leper hospital, and, during several of my visits, a game of base ball was going on in front, and the usual crowd swarmed as lookers-on upon the hospital steps.

The public are admitted to worship in the lepers' church without restraint. At my visits the lepers gathered around me closely, and many offered freely to exchange their small and filthy paper money for silver, all willing to submit to any professional examination in their earnest desire to get relief. It is needless to say that the infected paper money finds its way into the pockets of the general public, and becomes a fertile source of contagion and infection.

I have been very much interested in the case of Joseph Miller, one of the survivors of the massacre of the crew of the filibustering ship, Virginius, in 1872, who was a leper inmate of the hospital. His name has been corrupted into Amelio by the Cubans. At the time of his rescue, he was a hale and hearty dark mulatto, but thirteen years of leprosy had turned him white; it has also made him handless, footless, sightless, noseless; it has left him without ears; it has left him without what would be recognized as a human voice; it has left him a hideous, ghastly creature, without hope in life; a mere thing, whom to look at is to make the stoutest heart shudder; whom to touch is to take the greatest possible risk of contagion that is sure to destroy. And such destruction. No other cruel thing known is so cruel, a weary journey of years, with weary limbs over which there is no power; shunned as no other being is shunned, cast out as unclean, to await the day when the horrible, hideous mass of decay will cease to live.

Whatever be the pathology of leprosy, there can be no doubt that it is a disease affecting nutrition, and which does its deadly work by absorption or ulcerative absorption of the tissues. For example, in the early cases, there will be seen on close inspection, a slight tumefaction of the skin and cellular tissue at a point on the ear, or nose, or limb. Later on there will be a gradually encroaching constriction at or near the point, and a slow absorption or amputation of the member or part. In some other early cases there is a strange alteration in the countenance and plaques of skin on the face and body, altered and bleached, or rendered livid by defective nutrition, or local inflammation.

The uninitiated might suspect syphilis, but when once seen and studied in its manifold

forms it can scarcely be mistaken. The limits of time and the subject announced, as the order of this meeting, prevent me from going farther into the subject at present.

A HISTORY OF A CASE OF DOUBLE PNEUMONIA ILLUSTRATIVE OF THE ABORTIVE TREATMENT.*

By ADOLPH KORNIG, M. D,
PITTSBURGH, PA.

The following case of pneumonia may perhaps be deemed worthy of recital before this society. I present it for your consideration and comment. Be the initial cause of pneumonia whatever it may, I am firmly convinced that the consolidation of the lungs is due to excessive efforts on the part of nature to repair the damage that has been done to the extraordinarily vascular lung-tissue, and to guide, or more properly, to restrain, the reparative forces, is the course that would seem to be indicated in the treatment of acute lobar pneumonia. In exemplification of this line of treatment of an acute pneumonia I submit the following history: One week ago to-day at 8.30 o'clock in the morning I was called to see Mr. J. R., aged 37. The night previous, while conducting the calcium light arrangements in one of the theatres, he experienced acute shooting pains in his chest, but remained at work till the conclusion of the play. Shortly after arriving at his home, about one o'clock, he was attacked with a severe chill and suffered intense pain about the region of, and somewhat inferior to the left nipple. From that time till I saw him he suffered unremittingly, in spite of thorough application of mustard. His breathing was so difficult that the first glance was sufficient to locate the cause of his illness in his chest, and closer investigation revealed the following conditions: Pulse 108, temperature 102½°, face flushed, respiratory movements very painful and abrupt. Auscultation over the front of the chest revealed roughened respiratory murmur, but on account of the suffering of the patient the physical examination of the lungs was not very perfect. A rather profuse and extraordinarily well marked rusty expectoration, however, satisfied me as to the condition of the lungs when conjoined with the other superficial symptoms. The cough, by reason of pain, was suppressed as much as possible. The first requisite to my mind was to relieve the pain, which was accomplished by a hypodermic injection of one fourth grain of sulphate of morphine and one one-hundred and fiftieth of a grain of sulphate of atropine. The second indication to my mind was to divert the blood stream and reduce the heart's action. With this end in view I gave him a hypodermic tablet of hydrochlorate of apomorphine of the strength of one-tenth of a grain. This I gave dry on his tongue and it would, I hoped nauseate him somewhat and initiate diaphoresis. I then wrote the following prescription:

℞ Tincturæ veratri viridis.....gtt. L.
Sodii salicylatis..... ..... ʒ iv.
Syrupi senegæ.....f ʒ iij.
Aquæ menthæ piperitæ q. s. ad f ʒ iij.
M. Sig. A teaspoonful every 2 hours.

Being a man of vigorous health, weighing about 165 pounds, I considered two drops of the veratrum none too much, even conjoined with the ten grains of salicylate of sodium every two hours. The salicylate was added for the reason that some five or six years before I had attended the same patient through an attack of acute articular rheumatism, and thinking a similar influence might possibly be associated with his present illness it was added for both its anti-rheumatic and its its diaphoretic and heart sedative action.

The first dose of the prescription mentioned was given him about nine o'clock. At 3.15 P.M. he was bathed in perspiration, earning his life by the sweat of his brow, as it were; his pain was less severe, pulse 98, temperature 100°, and his cough was somewhat relieved. His expectoration was strongly tinged with a rusty color. During the time of my visit he became sick at the stomach, and vomited some grumous fluid, evidently the result of the apomorphine administered earlier in the day. At 10 P.M. his pulse was 88, temperature, 99¼°, pain much relieved, face less flushed, but the perspiration was still profuse. I ordered the mustard to be reapplied.

Feb. 10. 10 A.M. Pulse 80, temperature 98¼°. Countenance almost normal in expression and color. Sputum somewhat less markedly tinged, cough slight, pain produced only on deep inspiration, slept well during the previous night, diaphoresis still profuse, urine highly colored and viscid. I ordered a solution of citrate of magnesium in wineglassful doses to quench thirst and relax bowels. Thinking the severity of the attack overcome, the veratrum and salicylate were reduced to one-half the former dose.

Feb. 10. 6 P.M. Pulse 80, temperature 99½°, face a little more flushed, cough moderate, sputum rather more deeply colored. Full dose of the veratrum again resorted to. Diaphoresis less profuse.

*Read before the Allegheny County Medical Society.

Feb. 11. 9.30 A.M. Pulse 72, temperature 98½°, patient passed a comfortable night, slept considerable, cough slight, sputum still red but more faintly so, diaphoresis slight, face almost natural in color. During the past 48 hours, the patient was so moist with sweat, and was withal doing so well that it was thought best not to subject him to a physical examination of his chest. At this time, however, an examination was made, and the base of the left lung, posteriorly, was found somewhat dull on percussion, and over an area of about the size of a hand distinct crepitant rales were heard; on the right side over a smaller area the same condition was discovered, but the rales were more of a submucous variety. The fifty drops of tincture of veratrum viride and the half ounce of salicylate of sodium being exhausted, the prescription was ordered refilled, and continued in slightly reduced doses. Another bottle of magnesium was also ordered.

Feb. 11. 6 P.M. At this time the patient was seen by Dr. Pettit, who found his temperature to be 100⅛°, and pulse 73. The crepitant rales on both sides were also noted by him. Diaphoresis and cough slight, pain almost absent. The pulse being reduced to about normal, he lengthened the interval between the doses of medicine to three hours.

Feb. 12. 10.30 A.M. Pulse 64, temperature 98°, patient rather pale, but feels well, expectoration still colored, cough less frequent. no pain, crepitant rales more moist, though still well marked. I discontinued the veratrum and salicylate, substituting for it the following prescription:

℞ Potassii iodidi.....5 i
Syrupi pruni virginianæ.....
Aquæ Foeniculi aa.....f 3 iss.
M. Sig. A teaspoonful every three hours.

Feb. 12. 6 P.M. Pulse 72, temperature 98¼°. General condition excellent. Patient begins to desire food.

Feb. 13. 11.45 A.M. Pulse 60, temperature 98°, cough rather increased, but expectoration more scanty though still tinged with yellow, crepitant rales still recognizable on both sides, though more moist in character. The medication was reduced to one-half teaspoonful every four hours, and the patient was allowed to sit up part of the day.

Feb. 14. 5.30 P.M. Pulse 64, temperature 98¼°. The patient sat up all day. His appetite was good, and he was without pain. His cough was almost voluntary, but at the base of the left lung slight mucous rales could still be heard. His expectoration was colorless, and his general condition, aside from the reduced pulse rate, normal.

In the absence of consolidation and bronchial breathing some may perhaps be inclined to doubt the genuineness of the pneumonia, but when we consider the powerful influence to which the patient was subjected prior to the time when these symptoms could have been developed, their absence is easily explained. The subnormal temperature and especially the subnormal pulse, after the cessation of the inflammatory process might be considered analogous to the hypnotic, or even narcotic effect often seen after the passage of nephritic calculi where a powerful anodyne was administered, during the passage of the calculus, without, perhaps, entirely allaying the excruciating pain.—(*For discussion see Society Reports.*)

POST-PARTUM HÆMORRHAGE.*

By ROGER WILLIAMS, M D.,
PITTSBURGH, PA.

I merely desire to call your attention to a few notes on the subject of post-partum hæmorrhage, with a view of presenting a subject of interest to all engaged in the healing art, and calling to mind the conditions that eventuate in the great hæmorrhages following delivery. There is no time when action is more promptly required, and knowledge and wisdom brought into play, than, when alone one is brought into the presence of post-partum hæmorrhage. It is unnecessary to present the picture, for one experience traces as with a stylus the tablets of memory more vividly and truly than ever artist's fingers wrought, and the whole play is necessarily so briefly enacted that we recall each incident, as we would describe a landscape seen in the lightning's flame. There is no emergency in the physician's life that gives less time for consultation and reflection, and no time more exacting to do the right thing, at the right time, and in the right way. Post-partum hæmorrhage is one of the most frequent complications of delivery. Call to mind, if you please, the many conditions you guard against in a labor about which you have doubt, and, in a vast majority, post-partum hæmorrhage is first to be feared. There is something more than intuition that places one on guard, for in the vast majority of subjects to this complication we find indisputable indices pointing to the subject in question. The patient, by reason of our wrongly-directed civilization and her whole surroundings, has engrafted a lax habit of body, inviting uterine inertia, and as a conse-

* Read before the Allegheny County Medical Society.

quence, post-partum hæmorrhage. We find illustrations of this in the upper ranks of life for they are most prone by reason of the demands of society. Education plays a part also, in inducing a premature and unhealthy development; and in support of this, I call to mind a home, almost palatial in its furnishment and surroundings, where a subject of post-partum hæmorrhage resided, and the intellectual food for thought was furnished by Boccaccio and the Queen of Navarre. Comment is unnecessary, for to the young ladies of that home, so surrounded at a period of life when quiet is most essential, the reading of such books is but the sowing of dragon's teeth, with the harvest in anticipation. Among the causes contributing may be mentioned the site and size of the placental attachment. A placenta attached to the fundus may have slight uterine attachment, and the uterine sinuses closed by nature's processes. Where the placenta is thin and covers a great surface, we may have ecstasis of the uterine vessels, and as a result, hæmorrhage. Local œdema, induced by perverted secretion, and inflammation, may prevent contraction, and as a result, we have immediate hæmorrhage. Complication to the funis, where it is interfered with and shortened, may cause a too rapid placental displacement, and therefore profuse hæmorrhage even before the child is extruded from the maternal parts.

A few years ago I delivered Mrs. G.—a multipara—and the cord, beside being tied in a knot, was entwined around arm and neck, and, during labor, the placenta was in part detached, causing a very great hæmorrhage. One peculiarity about this patient was her daily potations, which consisted of 16 ounces of tincture of opium, which she obtained clandestinely, and managed to keep her vice secret, until her maid was invited into my office, and the liquid measured not only one time, but many.

Retained portions of placenta is a frequent cause of post-partum hæmorrhage. I call to mind a case that occurred in my practice during my residence in Philadelphia. Mrs. S., 4½ months in the family way, was pushed off the pavement by a swinging gate, and fell in a sitting posture to the gutter. She promptly aborted, and as the placenta could not be immediately taken away, she suffered profuse hæmorrhage, which lasted until the placenta was expelled.

There may be a proliferation of the placental vessels constituting an extra or supplementary lobe, and the retention of this even after the placenta is removed will cause profuse hæmorrhage. Plural births, with double placentæ, is not an unfrequent cause of post-partum hæmorrhage, for at times the uterus seems to be irresponsive to all our efforts, and a hæmorrhage beyond what we desired is the result. I call to mind a case in illustration: Mrs. G. was delivered of twins, and the delayed second delivery was caused by an inertia induced by a beginning cancerous growth. The last delivered child was in part covered by a fleshy mass not unlike placenta, and was born dead.

Laceration of the cervix is a cause of post-partum hæmorrhage not infrequently. At times the structures of the uterine neck are hard and brittle, as well as unyielding, and, during labor, are apt to suffer to a greater or less extent. Mrs. W., a patient of mine, was delivered during my attendance at the A. M. A., at Nashville, and suffered an extensive laceration of the cervix, which was the immediate cause of an extensive hæmorrage controlled by styptic injections and plugging.

Lacerations in the vulval canal are not unfrequently the cause of violent and prolonged hæmorrhage. Mrs. D., a primipara, was delivered by me in December last, and there was a band of tissue broad as a common lead pencil joining the labia minora, which had escaped my examination, and when labor was completed the torn end of this small impediment caused quite a hæmorrhage, which was, with difficulty, controlled by applications of Monsell salt.

Growths within the uterus, even when too small to be detected during labor, are oftentimes the cause of alarming post-partum hæmorrhage.—I saw a case of this character with Dr. McNeil, the history of which he has kindly furnished. Mrs. K., a German, aged 38, confined December 16, labor lasting 24 hours, antero-posterior diameter narrow, delivery with instruments, and nothing marked the labor out of the natural order until the 11th day, when violent hæmorrhage occurred, keeping up until the patient was almost exsanguious. Prompt injections of hot water with vinegar, and teaspoonful-doses of ergot, relieved the hæmorrhage, and expelled a small fibroid, which was the cause of hæmorrhage. All went well until December 31, when during one of the quick atmospheric changes, the patient had a chill, rise of temperature, and died with pneumonic congestion January 5th.

As post-partum hæmorrhage is generally a preventable trouble, and where it often follows in a physician's path, rendering such a one open to censure for neglect or want of

knowledge, I claim your indulgence in this paper which may appear too long and tiresome—and yet we all have interest in a subject of such vital importance, not only to friends and family, but to ourselves, and this is my only excuse.

The character of a contraction has much to do with post-partum hæmorrhage. Admit we have a perfect contraction immediately after labor, if it is not permanent, and tonic, the relaxation may induce a fearful hæmorrhage. Post-partum hæmorrhage and permanent contraction are incompatible, I will admit, yet on examination one hour after labor and finding the uterus soft and flabby, and where coagula have not formed in the uterine sinuses, hæmorrhage will surely result.

Nature has her own way of controlling hæmorrhage by contractility of the uterus, and by plugging of the orifices of the uterine sinuses; and to assist by art when nature fails, is not an ignoble part the physician plays in attendance upon labor.

Not long ago, a physician left the bed-side of a patient with a violent post-partum hæmorrhage, with hurried direction to those who could not do what he should have done, in a fruitless quest for an instrument for transfusion. Had he gone for wings, in order that she might rise into the circumambient clouds, he should have been held less censurable, for when he returned life and hæmorrhage both had ended.

I need not speak of the secondary causes of hæmorrhage at great length, for that man who is not awake to the importance of the uterus worn out in a prolonged and exhausting effort in expelling the fœtus, or the uterus over-distended by excessive amounts of liquor amnii, or the consequences of a multiple birth, should not practice the obstetric art. Rapid emptying of the uterus is—excepting when filled with clots as a consequence of uterine hæmorrhage—baneful, jeopardizing and unskilful, and to do this to the over-distended uterus is criminal. The walls of an over-distended uterus are, to all intents and purposes, as paralyzed walls, and when the shock comes from relief of distension, it is the rule to expect retardation in contraction, and as a result, hæmorrhage of a greater or less extent.

The law is individual and not collective; and every mother is subject to the law controlling her case. True, there are principles governing, and likewise it is true we should be interpreters of the same, and should be ready at the instant to assist the tired and waning energies of the one harassed by the prolonged and exhausting pains of labor. But how many times is it true that we have hastened labor injudiciously, and reaped as the reward some complication that should not have existed?

The over-distended uterus should be relieved on the eve of labor by careful and minute rupture of the membranes, to allow the waters to slowly drain away. I know the ground taken is dangerous, but I am supposing judicious action, and there are examples of such action that have been praiseworthy to the operator, and to the one operated upon, helpful. I beg leave to cite an illustration: Mrs. P., enormously distended, a sufferer from ever-present pain, sleepless, and in constant dread lest she should never arrive at the day of acchouchement, was advised to have the sac of waters carefully ruptured; for two days there was a constant flow, and at the end of that time she went into labor, and was delivered of twins, one weighing 9¼ pounds and the other 8½. The uterus was firmly held for an hour to guard against hæmorrhage impending, and she made a rapid convalescence. An over-distended uterus is always a dangerous uterus, and should never be left until every indication is given that no emergency arises, especially as to hæmorrhage; for the greater number of deaths resulting from hæmorrhage during the last fifteen years in the Liberty Valley have been from this cause.

I am indebted to a brother practitioner for the following: Mrs. W., aged 23, delivered in November, 1891, labor normal, and of six hours duration; uterus greatly distended by amniotic fluid; secundines removed without trouble. Four hours after labor, profuse hæmorrhage set in, leaving the uterus spongy and enlarged. Contractility of the uterus weak, and as the patient could not take ergot, the hæmorrhage was kept in abeyance by injections of hot water for three hours, when it returned, with alarming conditions. Clots were speedily removed and warm water injected, controlling the hæmorrhage, but the patient was exsanguious, weak, and exhausted. Digitalis and stimulants were freely used, but the patient died on the tenth day from complication referable to the lungs. There was not at any time septic trouble.

Irregular contraction is a cause of post-partum hæmorrhages not uncommon. Part of the muscular fibres are relaxed, whilst part are in a state of contraction; the former often over the placental site, and is the cause of considerable hæmorrhage. By palpation this condition is easily discerned.

Hour-glass contraction is also a cause of post-partum hæmorrhage; rare it is true, yet nevertheless occurring. This condition follows often the obstetrician, who, by efforts of traction, excites uterine contraction at the seat of irritation—often the placental attachment, and many times the internal os, and, as a cause we have a diaphragm temporarily placed, with placenta in part or wholly included within the uterus, and hæmorrhage of a greater or less extent resulting. This condition rarely, if ever, follows after efforts of placental expression, and as this form of delivery of the after-birth grows into favor, hour-glass contraction grows less.

Encystment of the placenta is one of the rare complications of labor, and when it occurs, the placental site remains more or less paralyzed, whilst the remaining muscular fibres are in contractility. This form of trouble in the delivery of the after-birth is apt to be mistaken for adherent placenta, and oftentimes a part of it is left intra-uterine, as a result of wrongly directed effort, and hæmorrhage results, complicated at times by sepsis.

The placenta and membranes, and also the decidua, may be the seat of calcareous or fibroid degeneration, or the decidua may be abnormally thick. When an accident of this character to a part of the placenta or its membranes occurs, we have a cause of irritation not unlike a foreign body placed against the maternal tissues, and as a consequence, loosening of attachment in part, or an inflammation that causes adherent placenta. I think the many cases of adherent after-birth can be traced to one of the conditions mentioned; but, be this as it may, the hæmorrhage in this complication is not to be lightly considered, for the placental site is in a state of irritation, and its muscular fibres will respond freely.

Concealed hæmorrhage, following delivery, is a subject of interest to all. That fatal hæmorrhage of this character exists, many here will attest, and the obstetrician should ever be on guard. The flabby uterus rendered insensible, and worn out by long continued labor, may, by bleeding within itself, rob its subject of life. The external evidences of hæmorrhages may be normal, but where there is evidence of hæmorrhage the practiced eye detects at once. The conditions leading up to this are referable to clots, and at times membranes acting as a valve within the internal os. Illustrative of this, I am furnished the history of Mrs. ——, delivered at Homewood, in the summer of '91, who passed through a normal labor until the ninth day, when her physician was sent for, and found her pale, weak and bloodless. A syringe and hot water removed two quarts of clots. Phlebitis complicated the case, but the patient recovered.

Patients constitutionally predisposed to flooding are perhaps the most interesting of the class mentioned, and well merit the appellation of "bleeders." They follow the inclination of predisposition, in spite of every effort the physician puts forth, to a certain extent, and at times only mechanical pressure will relieve.

There are few sights more dreadful to look upon than the worst cases of post-partum hæmorrhage. A reign of terror ushers it into view, and that one who is at his post, equal to the occasion and to the emergencies that arise, has within him the elements of a hero. The pulse is a mere thread, or perhaps is imperceptible; syncope manifests itself, and with it is born a hope of thrombosis in the veinous sinuses; and yet there may be fatal syncope. Intense weariness and faintness comes on, and the patient, wildly tossing her arms, is with difficulty restrained. Respiration becomes gasping and sighing, suffocation seems impending, and the patient calls for more air. The skin is deadly cold, the face pale, and covered with profuse perspiration. If the hæmorrhage is not controlled, loss of vision, jactitation, convulsions, and death speedily follow.

The treatment in post-partum hæmorrhage, principally, should consist in using preventive measures. If the uterus is firmly held in contraction until the secundines are extruded, and the fundus held in the grasp of the hand until the first half hour is past; if only, when assured that permanent contraction has manifested itself, the binder is firmly applied, and, if a full dose of ergot is immediately given, cases of post-partum hæmorrhage would be much less frequent. If the history of the patient is one of post-partum hæmorrhage, then a greater care should be taken. It will be well to administer subcutaneously, a half hour before the supposed termination of labor, a full dose of ergotine. If then the os is dilatable, and one has prepared for the emergencies that *might* arise, rupture the membranes, and take advantage of every means to insure regular and, if possible, permanent contraction. If the pulse does not fall slightly below, or comes to the normal in 20 minutes after labor is completed, this in itself is indicative of inpending hæmorrhage, and then prompt treatment of tendencies, especially referable to relaxation, demands the intra-uterine administration of

remedies to control hæmorrhage. Ice, with uneven edges removed by immersion in hot water, carried to the fundus, and held until contraction is induced, or ice water—if the surrounding parts are protected—by injection, or water of the temperature of 120 to 130 degrees, by the same means, and persisted in until contractions are invoked. Absolutely hot water favors coagulation in the uterine sinuses, and in those nervously disposed, is a form of treatment suited. It is supposed that subcutaneous injection of ergotine has been used, or that ergot in the form of fd. ex. has been given in sufficient quantities. Antiseptic wool carried to the bleeding surfaces is to be used, and in the selection of remedies, there is the choice of dilute acetic acid, chloroform, or the mineral astringents. If a powder-blower is at hand, and the parts admit, the use of pulverized nutgalls will serve a goodly purpose, and is a safe means of arresting hæmorrhage. The application of tr. iodine is also efficacious, and can be readily applied on wool. Strength of the patient must be maintained, compensation for the loss of blood looked after, and to this end, injections of drachm doses of ether play a part, with the inhalation of nitrite of amyl, or the injection of stimulants. Alcoholic-saline intravenous injection gives back tension, and supplies, in part, the fearful waste. These failing, the abdominal aorta can be compressed, or the uterus held firmly by the hand sufficiently long to aid in the formation of coagula.—(*For discussion, see Society Reports.*)

INOCULATION OF PHYSICIANS WITH SYPHILIS.

Dr. James D. White, of Boston, says that he has notes of fifteen cases of syphilis in physicians who were inoculated upon their hands while engaged in professional duties. Three of these died from the disease. All of them suffered greatly in mind, and were more or physically disabled or disfigured for a time. He suggests (*Boston Medical Journal*): First, always wash one's hands immediately after an interview with a patient who has, or is suspected to have, syphilis, without regard to the condition of the parts touched, or even if not handled at all. This should be made an invariable custom. Second, the physician should regard every persistent sore upon himself, of whatever seat and however innocent apparently, as a possible lesion of tuberculosis or syphilis, and seek competent advice without delay. Such advice is never found at home.

SOCIETY REPORTS.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Scientific Meeting, February 16th 1892.

J. C. Lange, M. D., President, in the Chair.

Dr. Kœnig read a paper entitled "A History of a Case of Double Pneumonia Illustrative of the Abortive Treatment." (See p. 651.)

DISSCUSSION.

Dr. Rigg: I believe this is the proper treatment. It is the treatment that should be followed in pneumonia with very few exceptions. The selection, however of the particular cardiac sedative is the choice of the practitioner. I prefer aconite, but I will leave that entirely with the individual physician. In the early stage of pneumonia stimulants have been recently recommended and recently condemned; I think they are injurious; they are contrary to the effect you want to produce. I have been following that treatment for the last thirteen years, and I have no reason to regret it, no reason to believe that any other treatment I have seen, and have at times taken part in, is any better.

Dr. Duff: I was very much impressed with this case which is certainly well worthy of remembrance. My observation teaches me to believe that salicylate of sodium is one of the best remedies of this kind. I wish to call attention to the fact that salicylate of sodium is one of the most efficacious remedies in my hands, and in the hands of several practitioners with whom I have spoken on this subject. There is a condition in pneumonia analogous to that we have in rheumatism, and the operation of the medicine is to a certain extent in the same line.

Dr. Thomas: I wish to corroborate what Dr. Duff has stated, that salicylate of sodium is possibly one of the best remedies in pneumonia. In the *Pittsburgh Medical Journal* some years ago I gave the statistics of the continuance or the length of the disease, and the average limit of the disease as treated by salicylate of sodium. I look upon the disease as analogous in its character to rheumatism, and that both exist under a similar climatic condition, and that both require pretty much the one treatment. I do not remember what year my report was made, but if any of you wish to refer to it, you can get it in the journal published by Dr. Gallaher some years ago.

Dr. Daly: There can be no doubt that, viewed as a great controller of the heart's action in inflammatory diseases, veratrum viride is a very useful remedy. I have used it more or less for twenty years, but it has always occurred to me that a more important point, or quite as important a point, is to know when to abate its administration. It is so potent a remedy that unless good judgment is observed in abatement of the dose, serious harm may be done with it. I have for many years been in the habit of instructing the nurse to count the pulse, with the instructions that when the pulse fell to 95, with some moisture about the hands, to increase the interval of the dose and diminish its quantity to ½ or ¼ of whatever had been given, and with instructions that if the febrile action increased to increase the dose again.

With reference to the value of salicylate of sodium in pneumonia, I think many can testify to its value, but I presume it is of value because of the common origin, frequently, of pneumonia and acute rheumatism. I think every man who has been an observer in the practice of medicine for fifteen or twenty years, or even less, will come to the conclusion that many acute pulmonary affections, such as bronchitis and pneumonia, have their origin within the system, not without the system at all, from the retention of broken down products. What we may regard as a rheumatic condition may in one case produce rheumatism and in another case pneumonia, in another case rheumatic bronchitis, or even a rheumatic pleurisy; that I have demonstrated to my own satisfaction more than once, and therefore it is reasonable that salicylate of sodium gives such results as it does. It will also reduce temperature and the heart's action, and for prompt and efficient work it is very difficult to find a remedy equal to it; but one must know when to stop the remedy.

Dr. Borland: I have used tincture of aconite with about the same results as Dr. Kœnig has had with veratrum viride. Salicylate of sodium, in my experience has been satisfactory in many cases, but it is hard on the stomach, and for this reason I have not been able to give full doses. What is called salicylate of sodium, that preparation that is made use of in filling prescriptions, is a preparation I understand made from coal tar products, or, in other words, there is no true salicylate of sodium about it. Salicylic acid, which is made use of, is a synthetical product. I am in the habit of ordering the true salicylic acid and combining it with ordinary bicarbonate of sodium. I find that this combination is more easily borne, and has better effects.

Dr. Davis: I would like to state that I have never in private practice been able to give salicylate of sodium longer than twenty-four or thirty-six hours. In hospital patients, where we can control them, we can prosecute the administration longer, but I do not know a patient who can resist and will not resist after forty-eight hours. It is so repulsive that the taste is a factor in starting a rebellion in the stomach and palate of the patient.

Dr. Duff: Mr. Davis's remarks are certainly a revelation to me. As a rule, I have had patients taking large doses, very large doses, of it for a week at a time without any bad results.

Dr. Batten: I have been in the habit of prescribing salicylate of sodium in rheumatism, and I have often continued it for two weeks, and I have never found any bad results from the taking of it, or any effect on the stomach, nor found that my patient objected to taking it. I have thought that salicylate of sodium was pleasant to take.

Dr. Kœnig, in closing the discussion, said: I desire to recall the attention of the society to a statement that I made, which has, judging from the discussion, apparently been overlooked; it is namely: That the antiphlogistic action was initiated by apomorphine, one of the most powerful depressants and emetics in the entire pharmacopœia, and it probably had much to do with the abrupt termination of the pneumonia. I want also to express my appreciation of the danger that is associated with the administration of large doses of heart sedatives; for that reason I made three visits to this patient in one day. No doubt what Dr. Rigg and Dr. Borland stated, that many other remedies will accomplish the same result, is true. There are many roads that lead to Rome, though some may be more direct or otherwise preferable than others. Aconite or tartar emetic will accomplish the same result; but if I were to give aconite in sufficient amount to accomplish what the veratrum viride and salicylate of sodium did, I would want to sit at the bedside of the patient. I have no doubt it is an excellent remedy, more rapid in its action, and perhaps more certain, but unless closely watched, we unnecessarily risk the life of the patient. In veratrum viride there are two or more alkaloids, one of which is powerfully heart sedative, while another is emetic, but less marked so than the heart sedative one; before, however, the sedation can go to a fatal limit the emetic action is established and the stomach emptied of its remaining contents.

Dr. Roger Williams then read a paper on "Post-partum Hæmorrhages." (See page 652).

DISSCUSSION.

Dr. Davis: The doctor has not only opened the discussion, but he has so very thoroughly covered the ground that it leaves little room for any one to add anything, but rather repeat in the way of emphasis some of the statements he has made. There is one cause of post-partum hæmorrhage that I did not notice being mentioned, that is the use of anæsthetics in labor. I believe it is the experience of all that the use of chloroform or any other anæsthetic in labor, is very liable to leave the patient in such a condition that the normal stimulus of the last throes of labor are removed and a lassitude follows the removal of pain, so it is a question as to how to resort to anæsthetics. It is necessary to be very careful in following all the details the reader has mentioned, in regard to the pressing down of the uterus and holding it pressed and keeping it in observation all the time until the patient has rallied, and I think where this precaution is not observed, there are many cases of hæmorrhage as the result; not always fatal hæmorrhage, but a hæmorahage that would be avoided if these precautions were observed. The doctor has clearly outlined the magnitude and gravity of the diseased condition, because in a great majority of cases it is a diseased condition, a pathological condition, not a physiological one, and I know of nothing we are called on to attend that so alarms physicians and attendants as this. I recall the words of old Dr. Meigs when he so wonderfully demonstrated the condition. He would show us in so vivid a manner the accident; he would then mention the remedies to use, and he said after you have used these you will throw up your hands and wish to the Lord old Meigs was there. I tell you, it has come to us all over and over again, when these patients seem, in spite of all remedies, to resist every endeavor to bring that uterus down, we do wish for help from any source or from every source. I would like to emphasize the hot water. It is one of the more recent ones, and it is one I have had experience with myself. In hæmorrhage, where I have felt safe, I have introduced ice rapidly, large quantities and satisfactorily, but not so satisfactorily it seems to me, not so promptly and fully as in the use of hot water. Most houses now, at least all well-to-do houses, have syringes of some kind, and if this water has been thoroughly boiled and cooled sufficient for the purpose, it is disinfected by that means, and I think can be used safely in large quantities, and its action in causing contraction is very prompt, and even where that is not so prompt, it does constringe the vessels and at least the hæmorrhage is controlled.

Dr. Thomas: There is one place in the paper where the gentleman spoke of rupturing the membranes. Teachers of obstetrics advise not to rupture the membranes, but I hold and have always advocated such practice. I think after labor begins the sooner the membrane is ruptured the better, and in a large practice of obstetrics as a rule I have followed it. To produce artificial labor the membranes are ruptured, so I hold that after the full period of uterine gestation has arrived, the membranes are in the road. There is one other point the reader spoke of, and that is to give large doses of ergot. Now I think that is a mistake. If you give large doses you produce an exaggerated contraction, and if you have that, you necessarily have following an exaggerated relaxation, so that in giving it to control hæmorrhage, it is better to give small doses and give them oftener. If there is anything that raises large beads of sweat on a man's forehead, it is when he attends to a case of confinement, and after the delivery or before the delivery, he hears the blood rushing out. There is nothing in the entire practice of medicine that impresses a man more than that condition. Now you talk about ice, you may talk about syringes and hot water. If a man finds himself with such a case how in the name of common sense is he going to run and get ice, inquire of the parties if a syringe is at hand, and if not rush to the drug store and get one? The way the hæmorrhage flows out, if you wait your patient will be dead before you have these things prepared. Sometimes you can almost tell that a woman is going to have a hæmorrhage; I have done that more than once. Where I suspect there is danger of hæmorrhage, I take precautions beforehand to have a pint or two of vinegar. I do not tell this in the hearing of the patient, but I tell them I want a pint of vinegar and a clean kerchief or a small towel, and if I have hæmorrhage of that kind, I roll the towel around my hand, saturate it with vinegar, pass it up the uterus, and I have never failed to constringe the vessels and check the hæmorrhage.

Dr. Blume: The subject of post-partum hæmorrhage is certainly of importance to every physician. The doctor has fully given the different causes, as well as the treatment of this complication. I wish in the first place to call your attention to one point—

to the question—Is it possible to prevent post-partum hæmorrhage? My answer is, the proper management of the third stage of labor will render these accidents extremely rare. Unfortunately there is still a diversity of opinion as to what is the proper treatment in the third stage of labor. Some writers say the uterus must be grasped and firmly compressed as soon as the head emerges; some insist upon compressing the fundus as soon as the child is delivered. Some say it must be done about fifteen minutes after the delivery of the child; still others leave the separation of the placenta and its expulsion through the contraction-ring to the powers of nature. If you do this you do not need to be afraid of post-partum hæmorrhage; there will be very little blood lost under these circumstances in a very great majority of cases. It would lead me too far to demonstrate to you that this last view is the correct one. The observer will find that there is very little loss of blood, in some cases almost nothing; he will also find that the uterus remains more contracted if this plan has been followed.

As Dr. Thomas said, ergot, especially large doses of ergot, has the effect of over-stimulating. About three or four years ago I published a paper on this subject, and especially about the third stage of labor. I have not had one case of post-partum hæmorrhage within the last eight or nine years since I have been following this plan of treatment of the third stage of labor, I say of post-partum hæmorrhage, and I exclude all those hæmorrhages which arise from lacerations. As regards the treatment, I again agree with Dr. Thomas, that it is often impossible to use cold or hot water. You have not the time to do it. If it is some mild form of hæmorrhage compression of the fundus will arrest it; if it is a serious hæmorrhage, you lose too much time before you have it ready. If I had it to do, I would simply introduce my hand into the uterus, take the other hand and grasp the fundus and make a compression of the uterus. I think very few cases will resist this treatment. The best result has been obtained in various cases by tamponing the uterus and vagina with iodoform gauze.

Dr. Batten: I venture to say that if any of us had a case of post-partum hæmorrhage to-night, we would not likely do anything that has been recommended, because we have not the appliances nor have we the time to wait. I believe that the husbanding of the second stage of labor to prevent post-partum hæmorrhage, is as important, if not more important than the third stage of labor. In my career I have had but two cases of post-partum hæmorrhage. One was not a very bad case. The other was a very bad case, and the woman finally died. I was not there at the time the child was born, nor for an hour afterwards, and when I arrived at the patient's side I found her *in articulo mortis*. I had attended her in three previous births. In another case of post-partum hæmorrhage, a case I saw with another physician, we governed the bleeding by each alternately holding or pressing the womb well down in the pelvis and giving ergot. The moment either of us would take the hand off the uterus it would become flabby. I am a great advocate of the rapid delivery of the after-birth when the second stage of labor is complete. It is very important that the clots and all the membranes that might remain in the uterus be removed, and that the womb should be well contracted before putting on the bandage. I would object to giving ergot in any shape, either by injection or by the mouth before the child is born, because I think it would lead to difficulties afterwards that might otherwise be avoided.

Dr. Kœnig: I want to say a word in favor of that much-abused remedy, ergot. According to my understanding the difference between ergot and the natural contraction is that the contraction by ergot is continuous. If you get the uterus contracted by large doses of ergot it does not relax. I myself have seen very few cases of serious post-partum hæmorrhage. I am sure, however, that if I had ergot at hand, I would give at least half an ounce of the fluid extract as soon as the manual manipulations should have succeeded in bringing about contractions, and time could be spared to administer the medicine.

Dr. Macfarlane: There is just one thing I wish to speak of—the matter of ergot. It was thought it should be given in all cases, and I think there are those who rely upon ergot to the exclusion of other things. I agree with Dr. Blume that the proper way of treating a post-partum hæmorrhage is to induce contraction of the uterus by the introduction of one hand into the uterus and place ing the other one upon the fundus. I think the presence of the hand in the womb is sufficient. There is one thing I wish to commend to those who have not done much such work, that the doctor has made mention of in this paper, that is, the significance of a quick, rapid pulse. Though quick and rapid you may not have a post-partum hæmorrhage in the true sense of the word, but you are going to have a uterus that will relax again

and fill with clots and give you trouble; and there are those who give ergot under these circumstances, and especially beginners will give the patient a dose of ergot. The proper thing to do is to empty the uterus with a few fingers, and usually the contraction will be sufficient to check such hæmorrhages without any ergot at all. Mention has been made of the binder, and I know people who put it on with as much regularity as they say their prayers at night. I think with the average woman, by the time you raise her up and have that binder put underneath her, you will do more harm than good. Even in hæmorrhages of any kind, it it not the custom with me to put on the binder. Once you have the uterus contracted, and you remain by your patient a length of time to assure you it is permanent, I do not think there is any occasion for the binder. Dr. Thomas has stated here that the proper thing to do under any and all circumstances, if full term has arrived, is to rupture the membrane. I wish to take exceptions to it. A labor can be carried through to such time as it will rupture of its own accord, with much more comfort, and it is certainly easier on the mother's part to have a soft bag than a resisting bag.

Dr. Murdoch: No man should introduce his hand into the uterus, unless for some such grave accident as this post-partum hæmorrhage, and only then when the post-partum hæmorrhage threatens to be fatal. I mention this because the matter was vividly brought to my mind last night by a young practitioner, who told me that two weeks ago he attended a case in which there was post-partum hæmorrhage, and for the purpose of arresting it he called for a syringe, and he injected it with hot water and arrested the hæmorrhage; but in a few days the woman was taken with fever and died within a short time, of septic poison. Now, if this goes abroad that in cases of post-partum hæmorrhage, the practitioner is at liberty to take a cloth or towel and wrap it in his hand and saturate with vinegar and push it into the uterine cavity, practitioners who have not had as much experience as Dr. Thomas has, get to think that is the proper course to pursue. Some of them may think that the loss of a few ounces of blood after delivery justifies them in the use of some such means to arrest the hæmorrhage, and they may for a trivial trouble introduce that into the system of woman which may cause her death. It is a serious matter to introduce the hand into the uterus, and in injecting hot water in a hurry, nine times out of ten you will not get water that is boiled, but that which is filled with septic matter; and you may for the purpose of arresting a hœmorrhage that will not prove fatal inject it in the system and probably cause the woman's death. I believe that, generally speaking, the hæmorrhage can be arrested without such means, but there are occasions where it is probably justifiable, and I have myself resorted to it. I am a believer in hastening the third state of labor; I believe in doing it according to the method of Crede. I also agree with Dr. Macfarlane that the binder is an obsolete means of producing pressure, and is not worthless, but worse than worthless—it is a nuisance.

Dr. Duff: I cannot help allowing the words of Prof. Hersh to ring in my ears. "Where a second case of post-partum hæmorrhage follows a man, he is certainly ignorant or guilty of negligence." When I say this I do not for a moment entertain the belief that cases of post-partum hæmorrhage are not a necessity in almost, if not every man's practice; not inevitable, but they should not be frequent, if proper precautions are taken. There have been remarks here to-night suggesting the impossibility of having proper instruments at hand. One certainly has a right to speak disparagingly of a physician who goes on his round day after day and night after night, waiting on the mothers of our land, without having himself provided with those instruments and remedies which may become necessary in the course of his practice, without time to run around and hunt them up; and hence while a physician does make a very great display when he has a table in the room and places his instruments upon it, which I would condemn to a certain extent, he is certainly practicing obstetrics according to the line of his duty, in being prepared for emergencies. Coming to the subject of post-partum hæmorrhage directly, the doctor did not illustrate the difference between the different characters of post-partum hæmorrhage, and in the discussion almost all have spoken of post-partum hæmorrhage which comes from the detachment of the placenta. Hæmorrhages from laceration are of different character, and it is very important that we recognize this difference. I know of a woman who died not five miles away from here, because her physicians did not recognize the fact that the hæmorrhage they were endeavoring to control did not come from the uterus, but from laceration. They kept the uterus pressed down, kept it contracted, and applied lemon juice and hot water, but the hæmorrhage went on, and the woman died; whereas, if they had recognized the true condition and taken hold of that

uterus and sewed the rent, they could have saved her in all probability. Now, with regard to the treatment, the doctor did not distinguish between contraction and retraction, as an element in post-partum hæmorrhage. We have contraction and retraction, and if you have plenty of contraction and not any retraction, you will still have hæmorrhage from the uterus. With regard to the use of ergot, it will produce contraction, but it does not produce retraction, either of the muscles or the blood vessels, and when the contraction passes off, not having retraction, you are a little more likely to have hæmorrhage than if you had not given ergot.

There are some methods of treatment of post-partum hæmorrhage that have not been mentioned. The condition of the patient must be taken into consideration, as has been stated by some one, outside of the condition of the uterus. If hæmorrhage came on, I would take the forceps and pull the uterus down, and with a pair of forceps I would take gauze and push it up into the uterus, and the hæmorrhage in ninety-nine cases out of one hundred would cease. I would never hasten to turn the uterus inside out as do Koch and others. Another thing to be done is to make pressure. I believe Beringer and Foster advocate pressure upon the abdominal aorta, one through the uterus, and the other the abdominal walls, and forcing all the blood that remains in the woman's body up to the brain as much as possible. The subject is a very interesting one to me, and I feel of all the operations we undertake there is none in which we must be braver, bolder, and more determined, and more active.

Dr. Williams: I do not intend to take much of your time. In regard to the criticism of Dr. Thomas, I did not state any dose of ergot; all I suggested was the injection of ergotine, when we anticipated in a few minutes to half an hour labor would be over to get the effect of ergot. In regard to the use of ergot, I am a firm believer in its value, that it will produce contraction. Some criticisms have been made on the binder. I mentioned that after you were assured that you had permanent and constant contraction, the application of the binder would more firmly hold the uterus to its place, not to immediately apply the bandage.

DR. R. STANBURRY SUTTON.

Dr. Sutton has been elected Gynæcologist to the Allegheny General Hospital, Allegheny, Pa., and given a separate building for his work, which he has already begun.

SELECTED FORMULÆ.

HYDROPSY OF CARDIAC ORIGIN.

℞

Digital s leaves.....ʒ ss.
Boiling water.....ʒ viii.
Make an infusion and add citrate of caffeine .....ʒ ss.
Tinct. strophantus.....ʒ i.
Acetate of potash.....ʒ v.
Extract of licorice.....ʒ i.

S. The whole to be taken in spoonful doses within 48 hours.

—*Union Médical.*

DEPILATORY.

℞

Carbonate of soda.....ʒ j.
Quicklime (fresh).....ʒ ss.
Powdered charcoal.....grs. viij.
Glycerin—concentrated.....ʒ j.
Lard—dehydrated.....ʒ viij.

M. S. A. After this has been applied for ten days the skin assumes a rose tint, and the hair may be drawn out without pain. It is imperative that the quicklime be fresh, and the glycerin and lard contain as little water as possible.

QUININE FOR INFANTS.

Lutz has proposed the following formula, which masks the bitter taste:

℞

Sulphate of quinine.....gr. viii.
Dilute sulphuric acid, 1 per cent.....♏ viii.
Essence of peppermint.....♏ v.
Saturated solution saccharine.....ʒ iiss.
Water.....ʒ iii.

—*Gazette des Hôpitaux.*

CAMPHOR IN INFLUENZA.

Dr. Deveruk (*La Semaine médicale*, No. 45, 1891) recommends camphor as one of the best remedies in influenza and similar states. He used the following formula in over 150 cases:

℞

Alcohol camphorat.....grammes 8.
Syrup chloroform..... " 10.
Mucilag. gumm. tragacanth..... " 60.
Aquæ..... " 180.

A spoonful every two hours.

CHRONIC PRURIGINOUS ECZEMA.

Unna suggests the following ointment in cases of chronic eczema, where there is considerable pruritus and deep infiltration of the skin:

℞

Calcii chloridi liquidi.....grammes 40.
Olei cadini..... " 10.
Lanolini..... " 20.
Unguenti zinci oxidi..... " 30.

—*L'Union Médicale*, Dec. 22, 1891, p. 899.

DISINFECTANT MOUTH-WASH.

The following combination has been found both a pleasant and efficient disinfectant:

℞

Thymol.....gr iij.
Benzoic acid..... " xl.
Tincture of eucalyptus.....ʒ iij.
Essence of peppermint.....♏ x.
Alcohol.....ʒ iij.

M. Sig. Pour enough in a glass of water to render it turbid, and use as a mouth-wash.

—*Thomas.*

CHLOROSIS.

Dr. Pick (*Wiener klin. Wochenschr.*), basing his procedures upon the supposition that chlorosis is due to an auto-intoxication by toxines absorbed from the stomach, washes out the stomach, in the morning, and administers immediately afterwards, some preparation of iron. With this treatment he has been able to get results in three or four weeks, where, under the ordinary method of administering iron, no results would be obtained for months. If this fails he prescribes:

℞ Creasote.....cgms. 5.
Sugar of milk..... " 30.
Sufficient for one capsule. Take one capsule immediately after each meal.

EXPECTORANT.

℞ Tr. opii camph.....ʒ i.
Srt. ammon. arom.....ʒ i.
Ext. ipecac fl.....ʒ ss.
Syr. prim. virg.....ʒ i.
Aquæ, ad.....ʒ viii.
M. Sig. A teaspoonful three or four times daily for a child.

CHILBLAINS.

Morrow prescribes:

℞ Carbolic acid,
Tannic acid.....āā 1.
Tincture of iodine..... 2.
Vaseline (albolene)..... 30.
M. Sig. Apply to the affected parts three or four times a day.

HYDROCHLORIC ACID IN DIPHTHERIA.

Roux and Yersin have shown that the virulence of diphtheritic toxines may be greatly diminished by the local application of small quantities of acid. Krazenski employs hydrochloric acid in the following formula:

℞ Perchloride of iron.....ʒ i
Medicinal hydrochloric acid.....ℳ xv.
Distilled water.....ʒ vi.
S.—A teaspoonful every 15 minutes for four doses, then every 30 minutes for 3 or 4 hours, finally every hour.

℞ Perchloride of iron.....ʒ ii.
Hydrochloric acid.....ℳ xv.
Distilled water.....ʒ i.
S. Apply locally every two hours.

—*Times and Register.*

FOR IRRITABLE HEART.

Dr. J. Hobart Egbert states that a young girl whose irritable heart did not improve under digitalis and belladonna (*Notes on New Remedies*) improved rapidly under the following:

℞ Chloralamid.....ʒ iv.
Tinct. belladonnæ.....ʒ ij.
Elixir simplic..... q. s. ad ʒ iv.
M. Sig. Teaspoonful three times daily, between meals and at bedtime.

And

℞ Ferri et quiniæ citrat.....ʒ iv.
Tinct. nucis vomic.....ʒ iij.
Syr. simplic..... q. s. ad ʒ vj.
M. Sig Teaspoonful after meals.

SEA FOAM.

(DRY SHAMPOO.)

℞ Alcohol.....ʒ vij.
Water.....ʒ x.
Ammonia water.....ʒ j.
Cologne.....ʒ j.
Tinct. green soap.....ʒ iv.
M. Use as a shampoo and wash off with clear water

SCROFULOUS OPHTHALMIA.

The following recipe was much used by the late Dr. C. Fronefield in this troublesome disease:

℞ Ext. belladonna.....gr. v.
Chloroform.....ʒ ss
Aquæ.....ʒ viij.
M. Sig. Wash two or three times daily.

Also:

℞ Quin. sulph.....ʒ jss.
Liq. potass. arsen.....gtt. x.
Ext. hyoscyami.....gr. iij.
M. et fiet. Pil. 60. Sig. One ter die.

ANÆMIA.

For a young girl fifteen years of age, Prof. DaCosta prescribed:

℞ Sodii arsenit.....gr. ¼.
Ferri sulphat..... " ij.
Potassii carbonat.....gr. ij.
M. One pill three times a day, the dose to be gradually increased.

Also a diet of fresh animal food, with green vegetables by forced feeding (four or five meals in the twenty-four hours), or if quantity is an objection, the freshly extracted juices of meat may be given. Red wines might also be given with advantage, and the patient should lead an out-door life.

ASTHMA.

Dr. Huchard, of Paris (*Le Bulletin médical*, No. 9, 1892), praises the following formula in the treatment of asthma:

℞ Iodide of potash,
Tinct. of lobelia,
Tinct. of polygala.....āā grammes 10.
Extract of opium.....dgms. 10.
Water.....grammes 900.
A teaspoonful morning and evening in a quarter of a glass of water.

The addition of the opium increases the tolerance of the stomach for the alkaline iodide; the iodide of sodium may be used fully as well.

VULVAR ECZEMA.

Lusch advises:

℞ Bicarbonate of sodium.....grammes 8.
Bicarbonate of potassium..... " 4.
Neutral glycerin..... " 6.
Tincture of opium..... " 8.
Water..... " 250.
Ft. sol. For use as a lotion morning and evening. After using the lotion apply a powder composed of starch 98 parts and powdered camphor 2 parts.

LEADING ARTICLE.

THE THERAPEUTIC USES OF IODOL.

Iodol is not one of the many new drugs that are taken hold of and used by the practising physician and then laid aside soon afterwards, not only as valueless but sometimes as dangerous remedies. Since its introduction in 1885 by Vulpius and Mazzoni, iodol has invited considerable attention, and to-day it may be said that the drug has, in conformity with its claims as a therapeutic agent, an undoubted value and obtained a permanent place in practical medicine. Indeed, few of the newer drugs have had such an extensive trial with such excellent general results. It has been employed both internally and externally, and has been found to be of special value as an antiseptic and alterative. As a whole, there is sufficient evidence to prove that it possesses superior advantages over corrosive sublimate, and especially over iodoform. A study of the literature regarding the therapeutic uses of the drug in question will sustain these assertions.

Iodol was first brought into notice by Mazzoni who largely used it in syphilitic disorders, adenitis, periadenitis and chancres, which were greatly benefited by it. Locally applied, it was found serviceable in the treatment of large suppurating ulcers, in which, in the course of 24 hours, it not only produced a lessening of the discharge but also a favorable change in the morbid processes, followed soon afterwards by a healthy granulation and cicatrization. As an antiseptic its good effects have been observed in erysipelas and diphtheria. Later studies have led Mazzoni to consider iodol an excellent remedy in the treatment of hydrocele, and of synovitis of the wrist-joint, particularly in the latter disease after the acute stage has passed. In such instances, pain and the disagreeable sense of heat have disappeared within 24 to 48 hours. Two cases of hydrocele were radically cured in 2 and 4 weeks respectively by the exclusive use of injections of a solution of the remedy.

Wolf has noticed that under iodol venereal ulcers heal more slowly, than under iodoform, but that, on the contrary, they do so more

rapidly when the lesions have been previously treated with salicylic acid.

From a series of clinical observations, Schmidt has found iodol superior to iodoform in the treatment of large suppurating surfaces, and in fistulæ. Unlike iodoform, iodol does not produce concretions on the borders of the ulcers, and thus it was seen that the healing was enhanced rapidly by the early formation of healthy granulations. Though extensively used by this author, in the form of powder and solutions locally applied to large suppurating cavities and surfaces, he has never observed symptoms of poisoning, as is of frequent occurrence in the case of iodoform.

Piermarino has reported success with the use of the drug in a large number of cases. Unhealthy granulations of the neck of the uterus, which came on as a consequence of a chronic endometritis, yielded completely to the simple application of an iodol ointment. The author cites the case of a child, four years of age, suffering from an umbilical phlegmon followed by gangrene, and by abscesses of the mammary region and suppurations of the root of the finger nails; powdered iodol, used locally, effected a radical cure. Identical results have been obtained by Piermarino in the treatment of fistula in ano, and gangrene of the vulva, when other measures had failed to do any good. A case of obstinate metrorrhagia, resulting from a chronic endometritis, was greatly benefited by the introduction into the uterine cavity of the powdered drug. These, indeed, are but few examples out of a large number of cases reported by various writers, cases in which the beneficial effects of the local use of iodol have been apparent.

Its uses, however, have not been confined to this field of action, and, as we have stated before, the agent under consideration has been employed internally with most satisfactory results. Thus, Pick, who has used it locally with decided advantage in the treatment of simple blenorrhagic catarrhs of the vagina and cervical canal, of suppurating and indurated ulcers, and other local troubles, has likewise extensively employed the drug internally. The author found that it was well tolerated by the stomach and that even in doses of from 2 to 3 grammes a day, it produced no deleterious effects, with the exception occasionally of a slight cephalalgia and looseness of the bowels, both of which, however, passed off rapidly. He also notes that its absorption is prompt and followed by the early appearance of iodine in the saliva and urine; that it was superior to iodide of potassium, especially in those cases of obstinate tertiary syphilis in which a prolonged action of the iodine is desired; and that, unlike the potassium salt, it did not produce stomatitis or nasal catarrh, even when large quantities were being eliminated by the saliva.

The same satisfactory results have been obtained by Cervesato, who more extensively, perhaps, than Pick, has employed the drug internally in a variety of diseases. The Italian writer has seen iodol do good in the various forms of scrofula, in scrofulous dermatitis, in scrofulous diseases of the mucous membranes, in the non-suppurating indolent tumors of the lymphatic glands, and others. In affections of the respiratory tract such as primary laryngeal tuberculosis, acute and chronic catarrhal laryngitis, dry suffocating catarrhs of adults, and in dry bronchitis of infancy, iodol, according to Cervesato, has exerted a beneficial influence. In three well defined cases of pleural exudation the drug enhanced absorption of the abnormal products.

Martin and Lublinski have produced cures with iodol, internally administered, in chronic pulmonary affections, and in laryngeal tuberculosis. The latter author has seen satisfactory results follow the use of iodol in ozæna, especially before complete atrophy of the mucous membrane and adjacent tissues has been established. In diseases of the nose and larynx great benefit has been obtained by Seifert. This observer has used the drug with success in atrophic rhinitis and in syphilitic ulcerations of the nasal pharyngeal cavities.

The statistics published by Szadeck are similarly interesting. He has employed suc-

cessfully, as a local application, iodol in 20 cases of soft chancres, 10 of gummous ulcerations, and in 7 of suppurating buboes. Internally he used the medicament in 17 cases of tertiary syphilis: 4 of gummous ulcerations and tumors of the skin and subcutaneous tissue; 9 of gummata of the pharynx; 2 of syphilitic ozæna with lesions of the bones and cartilages of the nose, and 2 of syphilitic hemiplegia. All these cases were benefited, and no untoward effects were experienced by the patients. Assaky has seen beneficial results from the use of the drug not only as a disinfectant and alterative, but also as an antiseptic in cases especially of infectious disorders such as erysipelas.

In ocular practice, iodol has been largely employed by Arago, has been especially studied by Juquer who found it of the greatest service in the following eye diseases: ulcerations of the conjunctiva; conjunctivitis accompanied with diphtheritic or purulent infiltration; primary or secondary ulcerations of the cornea; chronic affections of the lachrymal duct and suppurating dacryocystitis. Similarly good results have been obtained by Talenti, Hoffman, and Glassner in the treatment of catarrhal conjunctivitis and other eye disorders.

The same be said, according to the reports published by Shetler and Purjesz, regarding the therapeutic action of the drug in oral practice, especially in otorrhœas accompanied with caries of the osseous parts.

Stembo has found iodol valuable in the local treatment of diphtheria. Cerna and Valdes have employed it internally with success in the treatment of diabetes mellitus.

We could cite further evidence to show the great advantages obtained from the use of iodol in the treatment of disease, and of its evident advantages over iodine. We hope, however, that we have sufficiently impressed our readers with the great therapeutic value of this substance, and that the properties of the drug, carefully studied by the observers cited, may be taken advantage of by the general practitioner. This comparatively new remedy certainly deserves serious consideration and further trial.

We will conclude, then, by stating that iodol may be used locally in the form of the powder itself, or as an ointment in vaseline 2 to 10 parts, and in lanoline in the strength of from 5 to 10 per cent. It may be employed similarly dissolved in alcohol of the strength of from 5 to 10 per cent., or dissolved in ether of a strength from 10 to 20 per cent. Internally, it may be administered in daily doses of from 1 to 3 grammes, for adults; in children, from 1 to 3 decigrammes a day.

BOOK REVIEWS.

SLEEP, INSOMNIA, AND HYPNOTICS. By E. P. Hurd, M.D., Member of the Massachusetts Medical Society, etc., Detroit: George S. Davis, 1891. The Physician's Leisure Hour Series, Price, paper, 25 cents; cloth, 50 cents.

This number of the series was long announced to be a translation of the monograph by Germain Seé, published in the *Medicine Moderne*, but is really the product of the pen of Dr. Hurd.

In its preparation Dr. Hurd has made liberal use of the material he has published in various medical periodicals, and has given us a brochure that will fill a very acceptable place in many a physician's library. The first chapter treats of the physiology of sleep; the second of insomnia; and the third, and last, of hypnotics.

THE YEAR-BOOK OF TREATMENT FOR 1892. A Critical Review for Practitioners of Medicine and Surgery, 8vo., pp. 491. Cloth, $1.50, Philadelphia: Lea Brothers & Co., 1892.

In this edition of this standard synopsis of the year's progress in therapeutics the reader cannot fail to be satisfied with the work done by the twenty-one eminent practitioners who compiled it. With such an epitome from year to year, the physician can keep fairly abreast of the most important advances in therapeutics.

LECTURES ON TUMORS, FROM A CLINICAL STANDPOINT. By John B. Hamilton, M.D., LL.D., Professor of Surgery and Clinical Surgery, Rush Medical College, etc. For the use of students. Second edition. Detroit: Geo. S Davis, 1891, Price, paper, 25 cents; cloth, 50 cents.

It was but a few months ago that we had the pleasure of reviewing this little brochure, and of recommending it to those for whom it was written. The fact that a second edition is so soon called for is proof sufficient that Prof. Hamilton has supplied a want and very acceptably.

PERISCOPE.

THERAPEUTICS.

MENTHOL IN PRURIGINOUS AFFECTIONS OF THE SKIN.

Dr. W. Dubrenilk, of Bordeaux, uses menthol in all itching skin diseases with success. In urticaria, certain eczemas and in the itching following scabies after it has been cured it shows its greatest efficacy. In urticaria or pruritus without any lesion it may be employed as a ten per cent. solution in alcohol or oil. In eczema the alcoholic solutions may cause irritation, and as their action is more transient it is better to employ the solution in oil:

℞ Ol amygdalar dulc.....grams 100
Menthol..... " 6-10

Or a salve of the oxide of zinc and menthol, for example the following:

℞ Adipis, Vaselin } aa.....grams 25
Zinci oxydi... . ..... " 10
Menthol..... " 1-5

In case it is used upon the face, vulva, or excoriated surface, it will be necessary to lower the dose. It can, on the contrary, be elevated when the pruritis is excessive and more localized. Menthol has the advantages of being cheaper than cocaine and less odorous than peppermint essence.

ONANISM CURED BY HYPNOTIC SUGGESTION.

Dr. Bernheimer (*Revue de l'Hypnotisme*) relates an instance of cure of the habit of onanism, after the first *séance*, in a boy eight years of age, who had practised the vice for three years, and at the time hypnotic treatment was instituted admitted that he gave way to his desires as often as three or four times each night and two or three times a day. All other treatment, such as bromide of camphor, bromide of potassium, restraining apparatus, baths, special diet, intimidation, threats, etc., had failed. Suggestion during hypnotic sleep was repeated daily for a fortnight, the suggestion being that he would never again have an idea of touching himself either by day or during sleep at night, and that he would, henceforth, be strong enough to resist all temptation. From the first day there was marked general improvement, gain in weight, and entire freedom from the habit. Suggestion does not consist in an order not to do a thing, but in the confidence given to the child. It is the idea put into his brain that he would no longer succumb to the impulse.

THE ACTION OF THE CANTHARIDINATES.

Heryng describes (*Therap. Monatshefte*, November, 1891) the action of cantharidinate of potassium in twenty cases of combined pulmonary and laryngeal phthisis. There was pain after the injections, but this could generally be done away with by previously injecting a few drops of a 10 per cent. solution of cocaine. The injections were made with strict antiseptic precautions, at first between the shoulder blades, and repeated every other day. There was no inflammatory reaction or abscess at the site of puncture, but occasionally a small tender swelling appeared. Before each injection the urine was examined, and every week the body weight registered. Where there was no fever previously a rise 0.5° to 1° C. was noted in the temperature. In one case there was marked improvement in the voice, owing to the swelling allowing a more exact approximation of the cords. Expectoration was easier, but there was no diminution in the number of bacilli. The symptoms of urinary irritation, when present, were increased quantity of urine and a small quantity of albumen, with tenesmus and dysuria. They lasted a couple of days, and were relieved by opium. The details of four cases are given in full. Considerable improvement was noted in cases 1 and 3. In cases 2 and 4 the initial improvement was not maintained, one patient being lost sight of, and the other ultimately dying of his general condition. In the 16 remaining cases, 11 of which were very severe and 5 moderately so, the result was negative, the number of injections varying from three to fifteen. No positive result was obtained from any local application of the same solution to the larynx itself. Heryng agrees with other authors (1) that in early cases of laryngeal tuberculosis these injections bring about in some instances a swelling of the infiltrated parts, and a rapid cleaning of the floor of the ulcer; (2) that healing is thus favorably influenced; (3) that with 0.2 milligrammes no irritative effect is noted in the urinary system; (4) that the treatment is contra-indicated in severe cases of laryngeal tuberculosis, and also when the general condition is unfavorable, or irritative symptoms as regards the alimentary tract or kidneys are present; (5) that with doses of over 0.3 milligrammes these irritative symptoms appear; and (6) that a disadvantage of the treatment lies in a diffuse, rapidly-appearing local œdema, which increases the dysphagia. This œdema disappears of itself in a few days, but in case of out-patients it should be borne in mind.—*Brit. Med. Jour.*

ACID NITRATE OF MERCURY AS A CAUSTIC.

Hutchinson (*Archives of Surgery*, 1891) speaks highly of this remedy as an application in nearly all unhealthy sores, and wherever an infective process seems likely to involve the other parts. It is thus useful in boils, lupus, late syphilitic disease of skin or mucous membrane, and in phagedena. It should be cautiously applied with glass brushes of various sizes, any superfluity being taken up with thick blotting paper to avoid scar-formation.

TOXIC EFFECTS OF IMPURE CHLOROFORM.

As an experiment on animals conducted in the Pharmacological Laboratory of the University of Berlin, DuBois-Reymond (*Brit. Med. Jour.*, No 1622, p. 209) has shown that the toxic effects of chloroform are greatly increased by the presence of impurities. By the method of Pictet, of crystallizing chloroform by means of intense cold, it was possible to separate the pure drug from impurities. The latter occasioned greater frequency of pulse, greater depression of blood-pressure, and cessation of respiration more quickly than did the former.

INTRAVENOUS SALINE INFUSION.

Dr. Pye Smith recently reported the case of a man, who had suffered from profuse hæmorrhage after a severe gunshot wound of the leg. Amputation being necessary, but the patient unfit for it, a pint and a half of three-quarters per cent. saline solution was injected into his saphenous vein with marked improvement, and amputation just below the knee was performed. Circulation then failing again, another pint and a half was injected before he recovered from the ether, and at once his pulse and color were greatly improved, and in a few hours he had completely rallied, and subsequently made a good and rapid recovery.—*Medical Press.*

ANTISEPTIC PROPERTIES OF PEROXIDE OF HYDROGEN.

Dr. Paul Gibier (*Med. News*) says:

I believe that the practitioner will meet with very satisfactory results from the use of peroxide of hydrogen, for the following reasons:

1. This chemical seems to have no injurious effect upon animal cells.

2. It has a very energetic destructive action upon vegetable cells-microbes.

3. It has no toxic properties; five cubic centimetres injected beneath the skin of a guinea-pig do not produce any serious result, and it is also harmless when given by the mouth.

As an immediate conclusion resulting from my experiments, my opinion is that peroxide of hydrogen should be used in the treatment of diseases caused by germs, if the microbian element is directly accessible; and it is particularly useful in the treatment of infectious diseases of the mouth and throat.

OXYGEN AND STRYCHNINE IN RESPIRATORY TROUBLES.

Dr. Couper Cripps writes in the *British Medical Journal:* In view of the importance of the subject to which notice has been lately directed by Dr. Brunton and others, I would like to draw attention to an abstract of my M. D. thesis published in the *Liverpool Medico-Chirurgical Journal* for July, 1888. In this I advocated the use of oxygen for the respiratory trouble of coma in all cases, and, amongst others, related a case of opium poisoning which occurred in July, 1885, and which I treated successfully with the inhalation of oxygen, after artificial respiration had been previously maintained for over six hours without, apparently, any permanent benefit to the patient.

As regards the case of pneumonia related by Drs. Brunton and Prickett in the *British Medical Journal* for January 23d, in which venesection and the hypodermic injection of strychnine (apparently afterwards employed) failed to induce any marked effect, I may mention that in the case of opium poisoning referred to, dry cupping was resorted to over the chest and back, in order to relieve the extreme congestion of the head and neck, but it appeared to render the respiration more defective, and this was attributed to the withdrawal of blood from the circulation, diminishing its capacity for absorbing and carrying oxygen when presented to it in a dilute form.

It is thus possible that in Drs. Brunton and Prickett's case the venesection was the cause of the respiratory centre failing to respond to the hypodermic injection of strychnine, for in the following case of pneumonia a similar administration of this drug was followed by recovery:

M. B., a gentleman, aged about 42, had been going about suffering from symptoms resembling a mild attack of influenza for five days, and when first seen, on December 15th, 1890, presented signs of pneumonia,

limited to a small area outside the right nipple; this gradually extended until December 22d, when the entire upper lobe had become involved. The temperature, with slight remissions, had been about 104° F., and there had been almost constant delirium since the evening of December 15th, the mouth and the fauces were inflamed and thickly dotted over with an aphthous exudation, and on account of this and the dryness of the tongue swallowing was extremely difficult, and for the last three days nutrient enemata had been employed. The patient being thus in a critical condition, Dr, T. D. Acland kindly saw the case with me in the evening of December 22d, and gave a very gloomy prognosis. Dr. Sedgwick Saunders, who was attending from time to time in a friendly capacity, took a similar view of the case, although he was not able to be present at the consultation.

On December 24th I was called early to the patient, as it was supposed he was dying. On my arrival I found the friends firmly persuaded that the end was near at hand, one of the trained nurses having left with the impression that, such being the case, her services were no longer required. The condition of the patient was certainly alarming, for there had been several involuntary evacuations, enemata were no longer retained, there was retention of urine, and it seemed almost impossible to get him to swallow. He was quite unconscious, with teeth tightly clenched and face very dusky, constant twitching about the mouth, and convulsive movements of all the limbs. The respirations were slow and of a marked "Cheyne-Stokes" character, with long pauses at intervals, during which the patient became much cyanosed, and was on several occasions supposed, by his friends, to have breathed his last.

There being no time to obtain a supply of oxygen, which I have successfully used on other and somewhat similar occasions, I concluded the best thing to do was to stimulate, if possible, the respiratory centre, to the exhaustion of which the urgency of the symptoms appeared to be mainly due. I therefore obtained a solution of strychnine, and gave a hypodermic injection of one-fiftieth grain; a slight improvement soon took place in the breathing, and I was encouraged to repeat the injection after a short time, and at intervals of a few hours, until I had given the tenth of a grain; by this time the respiration had became quite regular, and consciousness had returned. The patient subsequently made a complete recovery.

I should mention that the case was complicated by a severe burn on the chest, caused by the application of a poultice on December 17th. This was an additional indication for the use of oxygen, could it have been obtained in time, for the gas has been shown to be of marked utility in cases of extensive burns.

DEATH FROM INJECTION OF COCAINE INTO THE TUNICA VAGINALIS TESTIS.

M. Berger (*Société de Chirurgie*, Paris, December 16, 1891) reports a case of death following an injection of cocaine into the tunica vaginalis testis for the cure of hydrocele by the injection of iodine. The patient was a young man who had a hydrocele which was very tense and as large as a turkey's egg.

As the hydrocele had developed very rapidly, M. Berger, fearing that it was a symptomatic hydrocele dependent upon some disease of the testicle, requested his interne to puncture it and examine the testicle; then, if it were found normal, to inject into the tunica vaginalis a tablespoonful of two per cent. solution of cocaine, cause it to remain a few minutes, then allow it to escape, and immediately afterwards inject the iodine, as had been done in a large number of cases without accident.

The operation was done exactly as directed. The interne injected a tablespoonful of a 1½-per cent. solution of cocaine into the tunica vaginalis, left it there hardly a minute, withdrew the whole quantity injected, and proceeded to inject the iodine. The patient was not conscious of any pain; he got up after the operation, and took his leave. In a little while he returned, complained of great weakness, and at once had convulsive movements of the face and limbs, clonic and tonic convulsions, tetanic contractions of the muscles, and finally became absolutely comatose, with abundant, bloody, frothy mucus exuding between his lips; his pulse rose to 130, and he died in cardiac syncope. Injections of ether and caffeine, artificial respiration, tracheotomy, etc., were tried, but without avail.

M. Richardière made an autopsy and found general congestion of the meninges and of the lungs, mitral insufficiency, and alcoholic lesions. The tunica vaginalis did not communicate with the peritoneal cavity. M. Richardière had made autopsies on eleven cases where death had been due to injections of cocaine.—*L'Union Médicale*, December 22, 1891, p. 898.

MEDICINE.

NEURASTHENIA AND ITS RELATIONS TO CHANGES OF THE GASTRO-ENTERIC TUBE.

Dr. Champagnac has published a monograph (Steinheil, Paris) upon this subject which is very extensive, and from a bibliographic and historic point of view this question is of real and unquestionable value. His conclusions are as follows:

1. The coincidence of dilatation of the stomach and prolapse of the right kidney and neurasthenic disturbances is absolutely incontestable.

2. One may, by directing one's treatment towards the dilated stomach, cure the nervous symptoms which accompany and follow it.

3. This treatment does not cause the dilatation to disappear, but prevents the auto-intoxication which is the cause of the neurasthenic symptoms.

4. Although the gastrectasia does not disappear entirely the patient ceases to be nervous.

5. In the pathogenesis of neurasthenic disturbances, we do not admit the theory of Glénard—enteroptosis—but that of Bouchard—the pathogenic importance of dilatation of the stomach.

6. We hold the nervous theory—Beard's—as insufficient and incapable of explaining the neurasthenic phenomena, even if they have preceded the dyspeptic symptoms.—*Gazetta degli Ospitali*, No. 25, 1891.

POST PALUDAL PNEUMONIA.

Hadji-Costa (*Rev. de Méd.*, November 10th, 1891) relates fourteen cases of post-paludal pneumonia. In Thessaly malaria prevails widely and at times so severely as to merit the name of an epidemic. Such epidemics occurred in 1884 and 1885. In the two following years there was no such occurrence but numerous cases of pneumonia were observed. A relation between malaria and pneumonia undoubtly exists. Three forms have been described: (1) The intermittent pneumonic fever of some authors in which each access of fever is said to be attended by some of the classical symptoms of pneumonia—this resembles the cases of intermittent pneumonia of non-malarial origin which have been recorded by some writers; (2) cases in which the malarial attacks occur regularly in the course of an ordinary pneumonia; and (3) cases which occur in those suffering from confirmed malarial intoxication, hence the name post-paludal pneumonia. Its onset is insidious, there is no shivering, hardly any pain in the side, and not much cough. Abdominal symptoms are frequently present—nausea, vomiting, slight jaundice, and loose stools. The temperature is intermittent, and defervescence slow; nervous symptoms often predominate. In the absence of history and physical examination of the chest, it is impossible to distinguish it from enteric fever. The prognosis is grave. The question arises as to whether the development of the pneumococcus upon a soil altered by malaria will account for the peculiar characters of the pneumonia, or whether the micro-organisms of malaria do not rather themselves bring about an inflammation of the lung unlike ordinary pneumonia. The author inclines to the latter view, and he points to analogous facts occurring in the other infective diseases. The treatment should be directed to the malaria.

A NEW VARIETY OF INTERSTITIAL NEPHRITIS.

Dr. John Arschagouni, in an article in the *Internat. Jour. Surg.*, says: The *Bulletin de Thérapeutique* published in one of its recent numbers a *new variety of interstitial nephritis*, described by M. Letzerich, and due to a *special bacillus*, short and fine, of crescent shape found in the interstitial tissues of the kidneys, at the border of cortical and medullary substances. also in the urine of the patient.

Symptoms:—Begins by an ill-defined malaise with fever and some gastric symptoms; such as anorexia, coated tongue, vomiting, great thirst, urine scanty, of a dark color, with uric acid crystals and abundant urates. This state remains from four to ten days, and after several vomitings suddenly appears œdema of the face, including the eye-lids and cheeks, also œdema of the feet, hands, and of the lumbar region, which becomes painful to touch; also some ascites, hydrothorax and even hydropericard are found. The œdema and dropsies always comes on with more or less complete suppressed urine, containing always of albumen, although less than in Bright's disease. Few renal epithelium and red globules are found and unsually no casts, but, on the contrary, leucocytes and bacilli are found in great numbers.

The temperature usually does not go over more than 39.5, sometimes 40.3. In such conditions attacks of eclampsia easily could be produced in children. Often, these is somnolency, and even a comatose state. In every case there is a very intensely generalized bronchitis; alternate constipation and

more or less profuse diarrhœa. Death may close the scene by uremia towards the end of the second or beginning of the third week; but the amelioration mostly follows a free micturition, which is dark at first and gradually becomes clear. At times, especially in adults, this disease may become chronic and continue for three months. Although the differential diagnosis of this variety from other nephritis is not difficult, the microscope settles the question more surely by the presence of these special bacilli in the urine.

The prognosis is favorable. M. Letzerich, upon forty-five cases of his own observation, lost only six, others have been cured from three to six weeks in children and from three to nine weeks in adults.

M. Letzerich has been able to isolate and cultivate these characteristic bacilli and, furthermore, he has produced by inoculation in animals an interstitial nephritis. Generally, children from two to thirteen years old are most attacked, but young men from eighteen to twenty-three years old haven't escaped it. The disease mostly occurs in the hot season, probably from impure water containing these bacilli.

It would always be a wise plan in any case of early stage albuminuria, to verify if the urine freshly voided contains any such bacilli or not.

THE BACTERIUM COLI COMMUNE AND PERITONITIS FROM PERFORATION OF THE INTESTINE.

In six cases of perforation in typhoid, which occurred at Florence during the past winter, Dr. Ottone Barbacci (*Lo Sperimentale*, August 15th, 1891) made careful observations of the peritoneal exudation. The perforation was always in the lower portion of the ileum; four times it was single, and in the other two cases two ulcers had given way close to each other. In each case cultivations were make on gelatine and nutrient agar; guinea-pigs and white rats were also inoculated with the exudation material. In four cases plate cultures were also made from the intestinal contents taken from the base of the ulcers, and also from the heart blood. In all six cases only one species of microbe developed from the cultures, and the author identifies this as the bacterium coli commune. The results of the inoculations on animals showed in three cases also the presence of the diplococcus lanceolatus capsulatus of Fränkel, but it was noted that the virulence of this was very slight, disappearing rapidly on being passed through the second animal. Very few and feeble colonies could be obtained from the blood of these animals, and the author thinks that this microbe was only an accidental impurity. He regards the bacterium coli commune as the true cause of the perforation and peritonitis. He appears to have satisfied himself that it was this organism, and not the bacillus typhosus of Eberth, which was present in his cases, although, as he himself admits, the distinction between these two species is very difficult. Much evidence has lately been advanced to prove the close relations between these two bacilli; but however this may be, the results above described are of great interest, as also is another case mentioned in the same paper—in which the author withdrew by aspiration some pus from a case of suppurative perityphlitis, and obtained from it pure cultures of the same bacillus.—*Brit. Med. Jour.*

A CASE OF DISAPPEARANCE OF SUGAR FROM THE URINE.

Dr. C. G. Am Ende, makes the following note in the *N. Y. Med. Jour:* Mrs. K., aged forty-two, mother of six children, menstruation yet regular but scantier, weight one hundred and twenty-one pounds, of good muscular development, no obesity, face flushed, was for the first time informed that she had diabetes about three years ago by Dr. ——, to whom she applied for treatment of lacerated cervix with consequences, but refused operation.

In the summer of 1891 the patient came complaining of severe gastric and neuralgic disturbances. Upon examination of her urine on the occasion of her next call, Fehling's solution caused a precipitate immediately upon its addition to the yet cold urine. The specimen brought contained considerable albumen, and after a few days a copious sediment of triple phosphates, some uric acid, a quantity of pus cells and *Bacillus termo*, very few epithelial cells, the majority from the bladder, but on one slide two cohering quadrangular cells with nodules similar to the tubular; no casts. Micturition frequent, slightly painful; the right kidney swollen and painful to pressure. No urine drawn directly from the bladder. Besides intra-uterine, the treatment comprised galvanization, strict diet, bismuth, with pepsin and pancreatin, bromide of sodium, and atropine.

On October 4th no sugar could be detected; there was also a decrease of albumen. Doubting the Fehling's solution, which was over a year old, a fresh one was prepared during the week.

October 11th.—Uric acid; again no precipitate. Doubting the fresh Fehling's solu-

tion, the juice of a grape was added to the yet hot mixture of urine and Fehling's solution, with immediate discoloration, etc., following. Albumen reduced to faint cloudiness upon boiling with nitric acid.

18th.—Uric acid. No sugar, no albumen, kidney not painful but quite an increase in phosphates. Specific gravity had risen to 1.024 from 1.015 on October 11th. It remains to be seen whether this rise depends on a limited allowance of bread since October 11th, or a transient exaggeration of diffused neuralgias, noticed, by the way, on two other patients with hysteric affections on Saturday.

The patient reported improvement in sleep since the beginning of the month, also increasing capability for housework. Except for a small allowance of bread, rigid treatment is continuing.

THE BLOOD IN SCURVY.

In the *Centralbl. f. Bakteriologie,* September 26th, 1891, reference is made to the work of Wieriuzskii, who examined the blood of scorbutic patients for micro-organisms. Cover-glass preparations were made in the first place, and examined both in the fresh state and after staining; a large number of colors was employed. No organisms were found. Next, blood from the finger and from scorbutic patches was sown upon various nutrient media, all the common and many uncommon ones being used. In all, 111 inoculations were made. Micro-organisms developed in 13 tubes only, and proved to be merely the common ones present in air, such as sarcina staphylococci, and B. subtilis. All the remaining tubes, both those which had been kept at the ordinary temperature and those placed in in the incubator, were found to be sterile. Finally, four rabbits were inoculated, each with several drops of blood. All remained healthy. These experiments support the view that scurvy is not a disease caused by micro-organisms in the blood.—*Brit. Med. Jour.*

(414) THE NUMBER OF LEUCOCYTES IN THE BLOOD IN PNEUMONIA.

M. Tchistovitch (*Annales de l'Institut Pasteur,* July 25th, 1891) has made some interesting observations on the cellular elements of the blood in pneumonia. It has been noted by several observers that in cases of pneumonia ending in recovery the blood generally contains a greatly increased number of leucocytes, while in fatal cases the leucocytes are diminished far below the normal number. The following experiments were made, with the object of elucidating the relation between the virulence of the diplococcus pneumoniæ and changes in the number of leucocytes in the blood of animals inoculated with this microbe. Cultures were obtained by inoculating a rabbit with pneumonic sputum, and on its death inoculating tubes of bouillon with the heart blood, in which diplococci abound. These broth cultures are at first extremely virulent, but on being kept at 38° C. lose their virulence from day to day. Having thus obtained a series of cultures of different virulence, these were used to inoculate rabbits, of which the leucocytes had been carefully estimated for some days previously by means of the hæmocytometer. After inoculation the leucocytes were again counted at stated intervals until the recovery or death of the animal. The following results were obtained: 1. Attenuated cultures caused in every case an increase in the number of leucocytes, which lasted one or two days, and disappeared with the recovery of the animal. 2. With virulent cultures, after a few hours even, there was marked diminution of the leucocytes, which became more evident till death took place. (This fact had nothing to do with the enfeeblement of the circulation, since it is very early apparent, when the animal is still quite lively and has an energetic circulation.) 3. The course of the disease was dependent on the virulence of the culture and on the resistance of the animal. A culture strong enough to kill a young rabbit failed to cause the death of an older one, and produced diminished leucocytosis in the former, increased leucocytosis in the latter. Sometimes, however, the course was not quite regular, for an animal would occasionally become at first very ill with diminution in the number of its leucocytes, then these would increase and recovery take place. Although this result still requires some explanation, it would seem to be certain that a benign course is closely connected with increased phagocytosis, a fatal course being marked by absence of phagocytosis. Thus, examination of the blood in pneumonia may be important from the point of view of prognosis.—*Brit. Med. Jour.*

SURGERY.

PRESENT ASPECT OF CEREBRAL SURGERY.

Dr. Landon Carter Gray in writing upon this subject in *The Alienist and Neurologist* for January, says that we do not yet know the cortical centre for temperature, pain, touch, and muscle sense. It is not always the case that the lesion is to be found on the opposite side to the paralysis; Sometimes it found on the same side. This is explained by the anatomical fact demonstrated by Flechsig, that in a small proportion of cases there is no decussation.

SPASMODIC WRY NECK.

Noble Smith F.R.C.S., Ed., in a recent publication endeavors to show that neither drugs, local applications, nor other general methods are of permanent use in the treatment of well-established wry neck. That electricity has failed to do permanent good, except in some recent cases. The nerve-stretching cannot with certainty be depended upon. That section and ablution of a piece of the spinal accessory nerve is certain to remove all spasm from the muscles supplied by that nerve, and is very likely to remove spasms set up in other muscles, although other nerves are apparently involved. That the most satisfactory plan of operation is section of the nerve upon the inner side of the sterno-mastoid before it enters the muscle. That when other muscles remain spasmodically affected, the spasms may be removed by section of the nerves supplying those muscles. That operations of section of the spinal accessory nerve, and of the posterior roots of the cervical nerves, are not followed by serious inconvenience from paralysis of the muscles. That there seems to be no risk of the reunion of the nerves, and return of the spasms after operation.

TREATMENT OF HYDROCELE.

According to the *Indian Medical Gazette*, no treatment succeeds better in ordinary cases of hydrocele than the injection of the tincture of iodine. It does, however, cause pain and may produce pyrexia, and iodism has resulted from absorption. Dr. Milliken has treated 54 cases by injection of strong carbolic acid: nine were not subsequently seen; four remained under observation, and 36 were cured; four required two injections, and five had to be injected three times. There was no sloughing, and no patient was more than a day away from business. Five to twenty-five minims of liquefied crystals of carbolic acid are injected through the cannula which evacuated the fluid. After removing the cannula the sac is lightly kneaded to distribute the acid over its inner surface.—*Bristol Medico-chirurgical Journal*, December, 1891.

GASTROSTOMY IN STRICTURE OF THE ESOPHAGUS.

At a meeting of the Glasgow Medico-Chirurgical Society, Knox (*Glasgow Medical Journal*, 1892, xxxvii, 1) presented a man forty-eight years of age, who for seven months had had progressively increasing difficulty in swallowing and loss of flesh. On examination, a stricture of the lower portion of the esophagus, impassable to a bougie, was found. As it was feared that the obstruction would ultimately become complete, gastrostomy was performed, the stomach first being sutured to the abominal parietes, and, after an interval of a week, incised. Not only was it an advantage to be able to successfully nourish the patient through the artificial opening, but it was found that as a result of functional rest swallowing became considerably easier.

ECHINCOCCUS OF THE LIVER OPERATED ON BY COSTOTOMY.

Th. B., a young Icelandic woman, æt. 20, entered the hospital with symptoms which apparently indicated a right-sided tuberculous pleuritis, namely, infiltration of the right apex, change in the voice, sweat, failure of the general nutrition and disturbances of digestion. Examination of the sputa was not then well in vogue in that hospital. As the patient began to have rigors and grow worse, a trial puncture was made without result. In December a great prominence of the right hypochondrium and epigastrium was noticed, while the anterior border of the liver was felt three inches above the umbilicus. Friction sounds were audible on the right side of the fossa infraspinata. December 13 a second trial puncture was made in the ninth right intercostal space and a small quantity of purulent fluid drawn off; this was examined under the microscope, but revealed nothing definite. As the diagnosis of empyæma was thought certain, the cystotomy was performed December 15, and a six centimetre piece removed from the tenth rib in the posterior axillary line. About 1,100 grains of fœtid pus were removed which contained large yellowish and gelatinous masses as well as the remainder of a number of torn membranes which presented a distinct stratification and were studded with prominences of

the size of a pea. No hooks could be found. The cavity could be felt below as a funnel-shaped hole piercing the smooth surface of the diaphragm. The patient bore the operation well. The purulent discharge diminished, but the wound could not be closed on account of the discharge of bile. The prominence of the right side decreased; several calcareous masses were removed. The patient's appetite and general condition improved, although she constantly lost quite a quantity of bile. The cavity decreased in size, the fistula contracted, the drainage-tube was removed; the patient increased in weight and had naturally colored stools. The fistula finally closed entirely, and the patient was discharged as cured February 23, 1887.

The writer cites two similar cases. Firstly, that of Krause (*Sammlung Klinscher Vorträge*, v. R. v. Volkmann, No. 325, 1888), where a yound man, æt. 27, presented an echinococcus cyst siturted upon the upper conxex surface of the liver necessitating, on account of the upward pushing of the diaphragm, the performance of costotomy and the opening of the cyst through the diaphragm. A drainage tube was inserted and the wound preserved free from irritation or infection, although a large amount of purulent fluid was discharged. Secondly, that of James Israel, (*Verhandl. d. d. Gesellschaft f. Chirurge*, viii, 1879, 1, p. 17), which was treated aftee Volkmann's method, costotomy, and as it could not be determined whether the diaphragm was adherent to the tumor the wound was tamponed with carbolized gauze for seven days, and finally an incision was made into the cyst through the diaphragm.—Dr. A. Brunniche in *Hospitals-Tideude*, No. 30, 1890.

CASE OF TRAUMATIC EPILEPSY TREATED BY TREPHINING.

Dr. Alexander Mills, writes: Four and one-half years ago patient was struck on the head with a large stone, from the effects of which he could not return to work for over a week. Six months later again received an injury to his head, being struck with a bottle which cut the scalp to a considerable extent. Was not rendered unconscious. One of the cicatrices is markedly depressed. On admission there was considerable twitching of the facial muscles, retracting the angles of the mouth as if the patient was trying to say "C" distinctly. Great difficulty in protruding tongue which was quickly drawn back. No paralysis of lingual muscles, but the spasmodic action of these caused some indistinctness in articulation. These symptoms came on about a year subsequent to his injury with the bottle. The muscles of the external ears and the occipito-frontalis contract from time to time. All his movements are exaggerated when he is watched and are suspended during sleep. Twitching movements occur at the metacarpo-phalangeal joints; there is occasional flexion or extension of the wrist joints, but never any movements of the elbow or shoulder; when standing, his toes twitch, those of the right foot especially; has dizziness and headache, which sometimes come on with vomiting; twitching of the eye-lids. Operation performed. A V-shaped incision was made over the depression on the left side, a little above and in front of the ear. On exposing the temporal muscle it was seen to be divided into two parts by a dense adherent cicatrix, which condition had simulated a depression of the skull. Trephine was applied with its centre over the cicatrix, and on removing the circle it was found to be normal, although somewhat thicker than usual. The dura mater was punctured with a small trocar and cannula and about an ounce of clear fluid drawn off. The dura did not bulge; it was thickened at one part. The vessels on its surface were then secured with double ligatures and divided, and a crucial incision was made into it. This exposed a bluish translucent cyst wall with a large vein coursing across it. There was a depression on the surface of the brain which measured about half an inch in every direction, but the brain tissue seemed healthy. The bone was not replaced. Wound dressed with iodoform gauze. After recovery from the effects of the chloroform jerking movements went on as before, affecting his tongue very much and making his articulation indistinct. Patient was difficult to manage. Remained in this condition for several days, being given chloralamid and hyoscine to keep him quiet. In a few days could speak a little better; spasms not so constant. Jerkings were much marked during sleep and also when greatly excited. About a month after the operation patient went home under the care of his brother. Was afterwards admitted to insane hospital, as he was somewhat dangerous and had threatened to kill his brother. He says this case is interesting in view of the fact that, although a distinct pathological lesion was found, and so far as could be, removed, no marked improvement took place in the condition of the patient. He says that it is possible that the pressure of the cyst had damaged the centres over which it was placed beyond the point from which they could recover.—*The Lancet*, Nov. 28, 1891.

OBSTETRICS.

INDUCTION OF PREMATURE LABOR BY GLYCERINE INJECTIONS.

Pelzer (*Centralbl. f. Gynäk.*, No. 2, 1892) gave a very satisfactory account of his experience of this method. He employs chemically pure, sterilized glycerine. A hundred cubic centimetres are thrown up between the membranes and the uterine wall. Full precautions are taken, not only against sepsis, but also against the entrance of air into the uterine cavity. In a short time regular pains set in. The membranes present well, and labor is usually easy. In two cases where labor was induced on account of contracted pelvis, the pains set in, in the first case, within half an hour, in the second after an hour. In a third case, the patient was at the end of the thirty-second week of pregnancy. For fourteen days she had been flooding; there was placenta prævia lateralis and a temperature of 104°. Glycerine was injected and pains set in an hour and a-half. Bleeding occurred two and a-half hours later. Turning was performed, and a dead child was delivered. The mother recovered. Glycerine injections are, in Pelzer's experience, valuable not only for the induction of premature labor, but also for accelerating delivery at term. In uterine atony it proves very efficacious.

RENEWAL OF MENSTRUATION AND SUBSEQUENT PREGNANCY AFTER REMOVAL OF BOTH OVARIES.

J. Anderson Robertson performed extirpation of both ovaries for cystic disease of these organs in a girl 23 years old. Three months after the operation she began again to menstruate. Five months after the operation she was married, became pregnant, and was delivered of a strong and perfectly healthy male child on October 25, 1890.

"From this very interesting case we may," says the author, "I think, learn several lessons. Amongst these are:

"(1) The truth of Mr. Lawson Tait's teaching regarding the starting point of menstruation—namely, that the ovaries are not causative of it. In fact, in this case, the presence of the diseased ovaries prevented it; normal menstruation was interrupted and the patient suffered from vicarious menstruation, as nose-bleeding, hæmoptysis, etc., and when they were removed normal menstrution followed.

"(2) The possibility of vicarious menstruation. The woman had brought up blood daily for months, but this ceased after the removal of the ovaries—that is, when normal menstruation became possible—and it has not recurred.

"(3) The proof that removal of both ovaries does not necessarily render a woman impotent. (An interesting medico-legal discussion might be raised on this point.) I was not aware of leaving any ovarian tissue. Indeed, my aim was to extirpate the ovaries thoroughly, and I thought I had done so. I suspect, however, that a small portion of healthy ovarian tissue had reached up to or beyond the hilus of the right ovary, and that this may have taken on regular ovarian functions. This, of course, is merely conjecture.

"(4) That in performing double oöphorectomy, except in cases of uterine fibroid, any apparently healthy portion may, perhaps, be left. I shall, at all events, keep this in mind in future operations."

NITRIC ACID AND CRIMINAL ABORTION.

Bellin, of Charkofi (*Nouvelles Arch. d'Obstêt. et de Gynéc.*, October, 1891, Supplement, p. 456), read before a medical society in that city a remarkable paper on eight cases of nitric acid drinking to produce abortion. The subjects took at first from fifteen to twenty drops of the acid several times a day, gradually increasing the dose. Severe symptoms appeared at the end of a month or six weeks. Abdominal pains, nausea, vomiting, constipation and subnormal temperature were observed, with remarkable mental symptoms. The patients also grew thin. In the first case abortion took place at the third month, and the patient was cured. In the second, abortion occurred at the same stage; the patient suffered miserably from abdominal pains afterwards, and ultimately killed herself. The third patient became insane. The fourth aborted at the fourth month and recovered. The fifth did not abort and recovered. The sixth committed suicide by swallowing matches, owing to the intense pain from which she suffered. Abortion occurred on the day before death. The seventh patient took the acid for two months without abortion occurring; she was syphilitic. The eighth, also subject to syphilis, took nitric acid for five weeks during the second and third months of pregnancy. She was delivered of a macerated fœtus on the sixth month and became insane. In all these cases where abortion occurred, it happened when the poisonous effects of the acid were most marked, or later after they had been counteracted. Bellin believes that the pathological changes caused by nitric acid depend upon the influence of that acid on the composition of the blood.—*Brit. Med. Jour.*

GYNÆCOLOGY.

MENTHOL IN PRURITIS VULVÆ.

Dr. Saalfeld, of Berlin, has found menthol, in a three to six per cent. alcoholic solution, to be more efficacious in this affection than either carbolic or salicylic acid solutions. He also obtained good results from a menthol-lanolin salve.—*Verhandlungen d. Dermatol, Vereinig, zu Berlin*, 1891.

OVULATION WITHOUT MENSTRUATION: PREGNANCY.

Loviot (*Arch. de Tocol. et de Gynéc.*, January, 1892) related, at a recent meeting of the Paris Obstetrical and Gynæcological Society, the case of a woman who had not seen a monthly period for fourteen months. Rheumatic pains set in and the abdomen became swollen. He discovered pregnancy between the sixth and seventh month. The mother did not believe in this diagnosis; nevertheless she was afterwards delivered of a very small child.—*Brit. Med. Jour.*

PRIMARY FIBROSARCOMA OF THE NASAL FOSSÆ.

Cisneros, of Madrid, (*Arch. Int. de Rinologia*, etc., February, 1892) records the case of a man, aged 46, who had suffered for about a year from gradually increasing obstruction of the left nasal passage, with profuse mucopurulent discharge and frequent hæmorrhage. On examination, the left fossa was found completely filled by a greyish mass with granular surface, painful, friable, and bleeding at the slightest touch. Posterior rhinoscopy showed vegetations of the growth projecting through the left choana. Examination with a probe showed that the tumor had a pedicle and that it sprang from the cartilaginous part of the septum. The mass was removed with the galvano-caustic loop, but immediately showed signs of recurrence. Vigorous use of forceps and cautery being insufficient to check the process, an incision was carried round the left ala, and, free access being thus obtained to the nasal fossa, tumor was removed as thoroughly as possible, the site of implantation being scraped with Volkmann's spoons and all suspicious points touched with the galvano-cautery; the fossa having been washed out and stuffed with iodoform gauze, the ala was replaced in position and sutured, the patient leaving the hospital on the seventh day. A fortnight later the growth had again recurred, this time perforating the septum and appearing in the right fossa. Forceps and cautery having again failed to stay the progress of the disease, both posterior nares were tamponed and the whole growth cleared out under chloroform with forceps and sharp spoons, nearly the whole of the cartilaginous septum being removed in the process. When seen a year later there was no sign of recurrence. The growth was examined by Dr. Mendoza, chief of the laboratory of the Hospital San Juan de Dios and pronounced to be a fibrosarcoma.—*Brit. Med. Jour.*

SCARIFICATION OF THE OS UTERI IN CHLOROSIS.

Dr. J. Cheron recommends scarification of the os uteri in chlorosis, and points out that this treatment has been highly spoken of by Schubert and other. The amount of blood to be drawn is about one gramme to every kilogramme of body weight. According to the above observers these slight bleedings greatly increase the number of red corpuscles and the amount of hæmoglobin in the blood. Dr. Cheron, in making use of scarification of the os in the treatment of old-standing disease in chlorotic patients, found that the general health as well as the local conditions improved. In many cases an analysis of the blood during and after treatment showed continuous improvement after each scarification. In chlorotic patients congestion of the womb is habitual, and it is easy to obtain forty to sixty grammes of blood at one operation. This local treatment seems likely to be of great benefit to chlorotic women, and it is easy to understand that it would be performed much more readily than venesection. The scarification, if done with antiseptic precautions, is not accompanied by risk.—*Lancet.*

A SENSITIVE TEST FOR ALBUMEN IN URINE.

The reagent is made by dissolving 8.0 mercuric chloride, 4.0 tartaric acid, 20.0 sugar n 200.0 water; the acid is added to produce a strongly acid solution and the sugar to increase its density. In applying the test the urine is acidulated with a few drops of strong acetic acid, filtered and delivered by means of a pipette into a tube half-filled with the reagent so as to form two layers. If the urine contains even less albumen than 1 in 50,000, there is produced immediately or before the lapse of a minute, a distinct white ring at the line of contact; the white ring is especially seen if the tube is held against a black background.—Dr. E. Spiegler, *Oesterr. Ztschr. f. Pharm.*, 1892, 65.

PÆDIATRICS.

PROPHYLAXIS OF SCARLATINOUS NEPHRITIS.

Dr. Ziegler (*La Semaine Médicale*, No. 4, 1892) puts his scarlatina patients upon a milk diet from the very first, and in over a hundred cases he has not seen a renal complication. During the first few days, when the anorexia is complete, the child is given a little milk, diluted with mineral water, when the appetite returns the child is given from a pint to three quarts of milk a day for the first three weeks, the milk is first boiled before administering. Now and then the child may be permitted to eat a piece of bread or a biscuit. This is continued in all its strictness for the first three weeks of the disease, to return gradually to the ordinary food.

EPIDEMIC OF CONTAGIOUS PORRIGO IN INFANTS.

Jonathan Hutchinson gives an interesting account of an epidemic of contagious porrigo (impetigo contagiosa) occurring in infants born in the maternity ward of St. Pancreas Workhouse, England. The starting of the epidemic seems to have been due to vaccination, but afterward no connection could be traced with the vaccine virus. The eruption was bullous, non-symmetrical, easily curable, of a local character, and with but little constitutional disturbance. It was decided that the wards should be closed for a month, and every possible means of disinfection should be employed. This was done; but on again opening the wards, after several children had been born and discharged healthy, the eruption again broke out. Several of the mothers contracted the disease, and it appeared on them as an impetiginoid eczema.—*Archives of Surgery*, January, 1892,

EXALGIN IN CHOREA.

Lowenthal (*Berl. Klin. Wochenschr.*, 1892, No. 5, p. 95), reports the results of the employment of exalgin in the treatment of thirty-five cases of chorea. Three grains were given three times daily; in a few cases the dose was given five times daily; in one case a grain and a half were given daily. The patients ranged from three to eighteen years of age. These cases presented all degrees of severity. The results were, on the whole, satisfactory; recovery was speedy in mild cases, retarded in severe cases. The duration of treatment was from a week to eight months. The results were the better the earlier in the disease the cases were seen. Unpleasant symptoms, such as tinnitus aurium, a sense of intoxication, disturbances of vision, vertigo, nausea, vomiting, jaundice, increased pain, headache, and cyanosis were observed in some cases in which the largest doses were employed; but these manifestations ceased upon the withdrawal of the remedy. It seemed as though a certain degree of tolerance of the remedy developed.

THE TEMPERATURE IN ACUTE PRIMARY PNEUMONIA IN CHILDREN.

As the result of a study of this subject, Holt, (*Archives of Pœdiatrics* 1891, No. 12) makes the following summary:

1. The predominating type of temperature in acute primary broncho-pneumonia is high and remittent, the daily fluctuations amounting usually to from three to five degrees Fahr. The sustained high temperature is uncommon except in the rapidly fatal cases. A low range of temperature—only two or three degrees above the normal—is not very uncommon, but is more frequent in fatal cases.
2. The termination of the fever is almost invariably by lysis.
3. The lowest mortality is among cases in which the fever lasts from eight to fourteen days; the highest is among those lasting but two or three days; the next to these the protracted cases, lasting over four weeks.
4. The day of highest temperature in fatal cases is usually the last day; in recovery cases there is no rule in this respect.
5. The lowest mortality is seen in the cases in which the highest point reached was between 103° and 104.5° F. Above 105° the mortality rises with the increase of each degree in the temperature. Abnormally low temperature are also to be dreaded, since they usually indicate a constitutional condition which makes recovery very doubtful.

TWO CASES OF HYSTERIA IN CHILDREN.

Dr. A. Selmer, of Balsfjorden, Norway, records two cases of hysteria in children which came under his observation. The first case was that of a 13-year-old girl of phthisical antecedents, who had overworked herself at school. She presented the characteristic picture, with maniacal attacks at times. She eventually recovered under electrotherapeutic treatment. In the second case, a girl of 10, the disease began under the guise of a febrile state resembling typhoid fever, together with a peculiar apathetic condition.

This continued for four weeks. She would then lie in an apathetic state with eyes closed, refuse to answer, and reject nourishment. By careful watching, it was found that she arose of nights and ate plentifully. This was kept up for seven months.—(*Norsk. Magazin for Lægevidenskaben*, No. 6, 1891.)

HYGIENE.

AN IMMUNITY-CONFERRING PRINCIPLE IN THE BLOOD OF ANIMALS TREATED WITH TUBERCULIN.

Having observed some degree of immunity in tuberculous guinea-pigs treated with tuberculin, Tizzoni and Centanni (*Centralbl. f. Bakteriol. u. Parasitenk.*, xi, 3 u. 4, p. 82) preceded injections of suspensions of tubercle-bacilli into the jugular vein by the introduction of the serum of the blood of such animals into the peritoneal cavity. Of ten animals thus treated, five died. All presented local lesions at the site of inoculation. In the fatal cases death was deferred and the visceral lesions were less extensive than usual. The view is expressed that tuberculin is, or the soluble products of the tubercle-bacillus are, capable of conferring a certain degree of immunity dependent upon the presence of an active agent in the blood, and that the good effects of tuberculin do not result from a direct action, but are dependent upon the generation in the body of some protective principle, which it is hoped future investigations will succeed in isolating.—*News.*

ANCIENT HINDU VACCINATION.

At a meeting of the Epidemiological Society (*Lancet*, February, 29, 1892), Dr. Pringle quoted a remarkable passage from an ancient Hindu work, which showed that true vaccination was known and practised in India centuries before the birth of Jenner: "The small-pox produced *from the udder of the cow* will be of the same mild nature as the original disease. . . . the pock should be of a good color, filed with a *clear* liquid, and surrounded by a circle of red. . . . There will be only slight fever of one, two or three days, but no fear need be entertained of small-pox so long as life endures." Pasteur's attenuation of virus by successive cultures has been applied in India for hundreds of years to inoculations with variolous lymph, which the document in question directed to be taken from "the most favorable cases," and he has seen series of such selected inoculations in which there was no general eruption, and the local phenomena were scarcely distinguishable from those of vaccination

INFANT MORTALITY IN FRANCE.

At a recent meeting of the Society for the Protection of Children in France Dr. Rochard (Chairman) stated that France loses every year 250,000 infants, and that out of this number there are at least 100,000 whose lives could be saved with intelligent care. These lives were the more precious in the present period, for France could no longer afford to lose them. When he stated, in 1884, that the population of France would stop increasing towards the beginning of the 20th century, he was pooh-poohed. His prophecy has been justified sooner than he wished. The number of deaths in 1890 outnumbered the births by 38,446. It was not easy, said Dr. Rochard, to add to the births, but it was possible to diminish the death-rate among infants. The 100,000 babes that ought to be saved every year would repopulate France. He then distributed medals and prizes awarded by the Society to doctors and nurses who had given their services to the Society.

PREMATURE BALDNESS AND ITS CAUSES.

Dr. Tyson's recent contribution to our pages on premature baldness, its causes and prevention, expresses the views that there is an increasing prevalence of premature baldness in men as compared with women, and that the cause is that men habitually wear heavier and more complete covering than women. We are not aware of any facts being adduced beyond Dr. Tyson's own impressions that premature baldness is more prevalent than formerly, and even if it were so we should still dispute his argument that the cause lies in the different character of the headgear of men and women. The difference, such as it is, lies deeper—viz., in the natural differences in the constitution of men and women as regards hair growth, and one element among these probably is the greater thickness and superior vascularity of the scalp in women as compared with men. Certainly the positions in which baldness first develops—viz., the upper part of the occiput, the vertex, and the temples—are all situations where the scalp is thinner than elsewhere; the sides of the scalp, for instance, which rarely become denuded of hair in what may be termed normal baldness. Indeed, the bald man seeks here the means to conceal his loss somewhat, and, by parting his hair immediately over his ear, and training what can thus be separated over the vertex, hopes that what he regards

as his defect may escape notice. Here we may remark that women lose their hair more frequently than is generally supposed, but are, from the arrangement and length of their coiffure, more successful than men in concealing it, and, if necessary, replacing the deficiency, while any such substitution by a man is like a town-crier proclaiming his loss to all beholders. Again, if the constant and more complete covering of the head were really the cause of baldness, it ought to be much more prevalent among the working classes, a large proportion of whom wear their hats or caps from morning till night; but few would venture to say that a larger proportion of them were bald than of those whose occupation employed the head more than the hands. Dr. Tyson's remarks on the general management of the hair seem to us sensible and sound as far as they go, but the addition of some form of antiseptic to the grease he recommends for occasional use would help materially in warding off that most frequent cause of baldness—seborrhœa capitis. When, however, the baldness exists as an hereditary failing, our efforts have to be confined to palliative treatment, directed towards delaying the process.—*Lancet.*

MEDICAL CHEMISTRY.

THYMACETINE.

At a meeting of the Berlin Gessellschaft für Psychiatrie und Nervenheilkunke on December 14th, 1891, Jolly gave an account of his experience with thymacetine, a substance prepared by Hoffmann, of Leipzig, which bears the same relation to thymol that phenacetine bears to phenol. Its chemical formula is as follows:

$$C_6H_2CH_3C_3H_7 \begin{cases} OC_2H_5 \\ NH(C_2H_3O). \end{cases}$$

It is a white crystalline powder, slightly soluble in water. Little is at present known about it from the pharmacological point of view beyond the fact that in two-gramme doses it does not cause toxic symptoms in dogs. Jolly was unable to test its antipyretic action, owing to the small quantity of the substance at his disposal. He found, however, that it had some effect as an analgesic. In seven cases of true migraine, thymacetine did no good, although the dose was progressively increased from 25 centigrammes to 1 gramme; but in other forms of headache it gave just as much relief as phenacetine. It has also some efficacy as a hypnotic. It was given in 26 cases of paralysis, delirium, etc., with insomnia, and in 16 it induced quiet sleep; in the remaining 10 the effect was *nil*. In patients who were in the habit of taking chloral, thymacetine appeared to produce just the same effect as that drug. The average dose required to induce sleep was 50 centigrammes. Among the secondary effects noted was acceleration of the pulse, the patients at the same time complaining of fullness, beating and noises in the head. Jolly thinks further trial is needed to prove the therapeutic value of thymacetine.—*Brt. Med. Jour.*

SALICYLIC ACID REACTION.

According to Schneegans and Gerock, the violet color resulting from the mixture of 10 cc. of a 0.2 per cent. solution of salicylic aldehyde with 2 cc. of a very dilute solution of perchloride of iron may be removed by shaking with 5 cc. of chloroform or ether. But if only 0.002 gm. of salicylic acid be added, the violet color remains persistent. A similar reaction occurs with the methyl ether of salicylic acid, and it may be used to detect as little as 1 part in 500 of free acid in artificial oil of wintergreen.—*J. Pharm. Els.-Loth.* and *Ph. Journ.*

MICROBES OF THE DEAD SEA.

For a long time there was doubt as to whether any organism, animal or vegetable, lived in the Dead Sea. Now the question is solved by a patient Frenchman, Dr. Lortet, who finds at last, in water from the Dead Sea, specific microbes of gangrene and tetanus. Inoculated rabbits promptly expire, which proves that the classic Lacus Asphalites is more alive than was formerly supposed.—*Ex.*

NITROUS ETHER AND ASTRINGENT DRUGS.

The probable cause of the evolution of gas in mixtures containing spirit of nitrous ether and fluid extract of uva ursi has been a fruitful theme in pharmaceutical literature these many years, and while the tannin of the uva ursi was by general consent asserted to be the exciting agent, no definite experiments were ever instituted to settle the question. The first step in this direction, so far as the writer is aware, has been taken by Mr. Leon C. Fink, who (*Notes on New Rem.*) experimented not alone with the effect of spirit of nitrous ether on various drugs containing an astringent principle as well as such in which no tannin is present, but he also employed tannin and gallic acid themselves. These experiments, some forty in number, have conclusively shown that tannin in contact with

nitrous ether is decomposed with the simultaneous disengagement of nitrous fumes, and this irrespective of whether the nitrous ether employed has an acid or neutral reaction. The nature of the reaction was not inquired into.

URINE TOXICITY IN THE INSANE.

Drs. Mairet and Bosc (*Jour. des Societes Scient.*, Nov. 11, 1891) state that in quiet mania urinary toxicity is the same as in the sane. In agitated mania the degree of toxicity is greater. In stuporous insanity the toxicity is less than in normal urine. In melancholia with stupor the urine was much more toxic and had toxic peculiarities. In melancholia the toxicity was increased in proportion as the anxiety increased. The urine had the same toxic qualities so far as regards myosis, micturition, the alimentary canal, and the circulation, but differed in the following particulars: Variations in temperature were produced. Hypothermy was first produced followed by hyperthermy, which was followed by a fall in temperature; sensibility abolition; diminution of reflexes; psychomotor disturbances, abulia, inquietude depression, anxiety, and auditory hyperæsthesia. In persecutory delusional cases toxicity is slightly greater than in normal urine. In senile insanity toxicity is less than in the urine of sanity. The urines of the insane may be grouped into two classes. (1) Those whose toxicity is not greater than the normal (senile insanity, calm period of certain psychoses). (2) Those whose toxicity is greater than normal. These last may be divided into two sub-groups: (A) Those in which the toxicity is more or less due to agitation or depression of the psychosis. (B) Those in which urinary toxicity persists independently of agitation or depression (melancholia with stupor, and certain manias). The toxic qualities of the urine of the insane are similar to those of normal urine so far as the alimentary canal, respiration, circulation, micturition, temperature, and even the nervous system are concerned. They may, however, so far as the nervous system is concerned, be divided into two groups. (1) Those in which symptoms due to normal urine are exaggerated. (2) Those in which symptoms are not produced by normal urine result. The first group includes certain cases of mania, and stuporous insanity. The second, certain cases of mania, melancholia with stupor, and melancholia. In cases where pathological urine merely reproduces the toxic tableau of normal urine, the degree of toxicity is due to an intensity more or less considerable of the disease, to agitation in mania, and depression in stupor when pathological urine gives rise to new toxic symptoms. These are due to the disorder itself. From this it results that by the side of psychoses produced by neurotic causes must be placed psychoses produced by disordered nutrition.

A RIGOROUS EXPERIMENT.

Interesting and perhaps important in point of utility, an experiment lately carried out in the Russian army must come dangerously near to censure if tried in the light of humanitarian principles. In order to ascertain whether tents would suffice to shelter troops in the field during severe winter weather, eight soldiers chosen at random were, it is stated, made to pass the night, or as much of it as they could endure, under such conditions. Every care seems to have been taken to provide these men with warm and heavy clothing, and the snow within the tent was beaten down and covered with mats and straw. The men slept comfortably from nine in the evening until nearly four next morning, at which hour the thermometer showed that the temperature, originally registered as 31° F., had fallen to 4° below zero, within as well as outside the tent. Nature could them endure no more; sleep was impossible, and the soldiers only saved themselves from freezing by taking exercise in the open air. Everyone can understand the bearing of such observations on practical warfare, and we would not lightly disparage their useful intention. Nevertheless, it is

something new to find the human species thus subjected to such an *experimentum in corpore vili*, and we sincerely hope that military necessity will not—as we believe it should not—call for its repetition. The recorded experience of Arctic voyagers—who have often camped out in tents—may surely now suffice for evidence as to the amount and quality of clothing and of tent appliances required to withstand the extremes of winter cold.—*Lancet.*

PHILADELPHIA POLYCLINIC HOSPITAL.

An examination for the position of two Internes and two Externes in the Hospital of the Philadelphia Polyclinic, will be held May 3, 1892. The Committee will meet and examine the candidates on the date named above, at 8 P. M., in the hospital building, Lombard Street west of Eighteenth.

A number of clinical assistants will be appointed. Those desiring to apply should present their claims to the Committee.

REMOVAL OF OVARIES FOR MOLLITIES OSSIUM IN NON-PUERPERAL WOMEN.

W. Thorn (*Centralb. Gynak.*, October 10, 1891) has observed two cases of mollities ossium. The first was in an early stage of the disease. She was still under treatment with iron, arsenic, and phosphorus, but without effect. In the second case the ovaries were removed. The patient was 32 years old, and had married in 1885. She bore three children, the last being born eleven months before the operation. After the birth of the second child the characteristic symptoms of mollities appeared, and increased during the third pregnancy, where labor was lingering and delivery completed by forceps. The disease afterward made rapid progress and caused great distress; the patient could not sleep owing to severe pain in the bones; the sternum was very tender to touch, and pulmonary symptoms set in. The case was much complicated by perimetritis. On November 9, 1891, the appendages were removed. The operation proved difficult for two reasons; the uterus was retroflexed and adherent; the pelvic cavity had become very narrow so that the necessary manipulations were difficult; the separated adhesions bled freely. The second complication was remarkable. The connective tissue of the pelvis was extremely œdematous, as seen normally in the puerperium alone; hence ligatures applied to the bleeding vessels on the uterine adhesions gave way, and the left tube was completely cut through when its ligature was being pulled tight. Thorn directs attention to this condition of the pelvic connective tissue, and asks if it be characteristic of mollities. After the operation, the pains in the bones rapidly disappeared, the sternum ceased to be tender to touch by the third day. On the fifth day uterine hæmorrhage took place, the temperature rose over 102° F., but soon fell to normal; the bronchial catarrh ceased, and the patient's general health became excellent. A show of blood occurred two months after the operation. The patient was then able to walk, though she waddled on account of the great changes in the pelvis and lower extremities. The disease was clearly arrested. Thorn is of Fehling's opinion, that mollities is an endemic reflex trophoneurosis of the bones, dependent upon the function of the ovaries, and that the removal of the ovaries is indicated as a cure for that disease.—*Brit. Med. Jour.*

TEST OF HYDROGEN PEROXIDE.

When a drop of a 10-per-cent. solution of metaphenylene-diamine chloride is boiled with a few drops of water and a drop of hydrogen peroxide solution, a carmine-red coloration is produced. This reaction will detect 0.005 mgm. of hydrogen peroxide in a drop of water, but is affected by the presence of nitrites. The test is thus modified, to be independent of the presence of the latter compounds: One or two drops of metaphenylene-diamine chloride are added to 1 cc. of ammonia solution containing a few drops of hydrogen peroxide solution. The mixture is boiled for some minutes, when the previously colorless solution becomes blue, of intensity corresponding with the peroxide present. Addition of alkali hydroxide solution changes the color to red.—G. Denigès in *Bull. Soc. Chem.* and *Jour. Chem. Soc.*

THE OPERATIVE TREATMENT OF EXTRA-UTERINE PREGNANCY IN THE LATER MONTHS OF GESTATION.*

By PROFESSOR R. FROMMEL,
ERLANGEN, GERMANY.

Gentlemen: Our knowledge and experience in the domain of extra-uterine pregnancy has wonderfully increased during the past few years, so much so that the report of additional cases would almost seem superfluous. Nevertheless, there are many things in connection with this subject that need further elucidation, and it is therefore desirable for us to profit by the complete histories of carefully watched cases. Last summer, in this Erlangen Clinic, we had two duplicate cases occurring within a week of each other: two cases of extra-uterine gestation, both of which led to operative interference. The histories of these cases are as follows:

Case 1. Mrs. E., a peasant's wife, 36 years old, came from a healthy family, and had menstruated regularly since her seventeenth year without any difficulties. She menstruated last during the end of May and first of June, 1890. The patient had previously given birth to three children, and apart from one attack of inflammation of the bowels, had never been ill. Since the cessation of her menses in May the woman considered herself pregnant. The course of pregnancy seemed to be entirely normal and not in any way different from her previous pregnancy. This went on until March 21, 1891, when she was taken with mild labor pains similar to those previously experienced. These continued for about five hours, and then gradually became stronger, especially in the ileo-cœcal region; the abdomen also became tender. This painfulness and tenderness continued for several days, the general condition of the patient, meanwhile, becoming seriously impaired. The patient became very weak and ill, and it was several weeks before she could leave her bed. Dr. Roderus, of Alerheim, who was called in two days after the appearance of labor, made a diagnosis of extra-uterine pregnancy, and as soon as the patient was able to be removed sent her to the clinic at Erlangen—this was on the fifteenth of April.

The patient was a woman of graceful build, with a slightly developed panniculus adiposus, and had evidently lost a considerable amount of strength. An examination of the heart and lungs gave no evidence of of any pathological condition. From the poorly developed breast a secretion could be pressed. The abdomen was enlarged and appeared as it normally would in the last month of pregnancy. The greatest circumference of the abdomen was 97 centimetres. It was hard and resistant to pressure. On account of the distention of the abdomen the various parts of the fœtus could not be located. The vaginal mucous membrane was relaxed and of a bluish color. The cervix was sufficiently enlarged to permit of the introduction of a finger, and bimanual examination easily revealed the fact that although the womb was enlarged to twice its normal size, it was empty and pressed against the left wall of the pelvis by the tumor. The left tube and ovaries could be easily distinguished by palpation, and were normal. The tumor containing the fœtus was attached to the right apex of the uterus by a stout thick pedicle. No ovary could be distinguished by palpation on this side.

The diagnosis was, of course, that of extra-uterine pregnancy, and its seat the right tube or ovary.

As all fœtal movements had ceased since the twentieth of March, it was taken for granted that the fœtus had died at that time.

* Delivered at the Woman's Clinic of the University of Erlangen, and translated from the *Munchener Medicinische Wochenschrift.*

In view of the rapidly decreasing strength of the patient, and the fact that she was constantly suffering with severe abdominal pains, an early laparotomy was decided upon in order to extirpate the fœtal sac.

The operation was performed on April 24, 1891. The abdomen was opened in the line of the linea alba, the incision being about 30 centimetres long. After the opening of the very thin abdominal wall, a pale red tumor could be seen through the gaping wound. Out of the lower angle of the wound a large quantity of black-brown fluid escaped, which was composed of coagulated blood and meconium, the odor of which being not unpleasant. Almost the entire tumor was adherent to the parietal and visceral portion of the peritoneum, although the adhesions to the anterior abdominal walls could be easily loosened with the hand. This having been done, it was discovered that the fœtal sac had burst at the lower portion of its left side, and that the head and one hand of the fœtus protruded into the abdominal cavity. The next step was to remove the fœtus through this rupture in the sac, and to ligate and cut the umbilical cord. The placenta, however, was left in the sac. The size of the tumor having materially decreased after the removal of the fœtus, the rest of the many adhesions to peritoneum and bowels were easily detached with but insignificant hæmorrhage. The tumor was now lifted out of the wound, and it was seen that it was attached to the uterus by a pedicle nine or ten centimetres long and four or five centimetres broad, and evidently consisted of the tube and the broad ligament. The pedicle was then tied with a number of ligatures and the tumor removed. During the operation a considerable quantity of blood and meconium was emptied from the tumor into the abdominal cavity, this was carefully soaked up with sterilized gauze napkins. Finally, a strip of iodoform gauze was placed from the back of the uterus in the pelvis, to the lower angle of the wound; the incision was then closed entirely, excepting a small point at the lower angle.

The fœtus which had been delivered was female, fully developed and only slightly macerated. It was noteworthy that the placenta occupied nearly half the space within the fœtal sac.

The subsequent course of the case was uneventful. During the first two days following the operation there was a slight elevation of temperature (to 38.2° C.), but after this the temperature remained normal and the pulse tranquil. A considerable quantity of a bloody fluid was drained out of the abdominal cavity by the iodoform gauze strip which had been placed in the wound, necessitating a frequent change of the dressings. On the fourth day the strip of gauze was removed and replaced by an iodoform wick, and this was removed three days later, all discharge from the wound having ceased. Two weeks after the operation the patient was up and about, and eight days later was discharged from the hospital.

Case 2. Mrs S., 31 years old. She had menstruated pretty regularly since her thirteenth year, but the flow had always been rather scanty. She had previously given birth, normally and spontaneously, to two children. Apart from the usual diseases incident to childhood she had had variola at the age of twelve, and typhoid fever during the twenty-first year of her life. She ceased menstruating June 25, 1890, and believed herself pregnant. The course of pregnancy continued undisturbed until October, at which time a series of difficulties appeared. These occurred periodically, and with the exception of brief respites, necessitated the patient's keeping in her bed all the time. These attacks consisted in intensely severe colic-like pains in the abdomen, and fainting fits, which latter were almost invariably occasioned when the patient made an attempt to leave the bed. There was also a constant desire to urinate and defecate, vomiting, etc. This condition lasted until the end of April, and then, since her physician had diagnosed a tumor at one side of the uterus, she was sent by Dr. Lang, of Baneberg, to this clinic.

Mrs. S. was a rather small, emaciated, and ill-looking woman, with a small frequent pulse. Her breasts were rather flabby, the areolæ were brown, but there seemed to be some discharge from them. The appearance of the abdomen corresponded with about the eighth month of pregnancy, the largest circumference being 92 centimetres. The tumor mostly occupied the right side of the abdomen. The fundus of the uterus, which was considerably enlarged, could be felt protruding above the pelvis on the left side. The tumor itself was dense and firm, and it was impossible to distinguish any one part of the fœtus. This, it will be remembered, was also observed in the case previously mentioned. In spite of frequent and most careful examinations no fœtal heart sounds or uterine murmur could be distinguished. Vaginal examination revealed the fact that the cervix was closed and was forcibly pressed to the left side by a tumor which was

attached to its right side extending well down into the pelvis.

The diagnosis was that of an extra-uterine pregnancy already considerably developed. It was impossible to say whether the fœtus was living or not, but the sufferings and increasing debility of the patient pointed to the advisability of an early operative interference.

The operation was performed June 6, 1891. The abdomen was opened in the line of the linea alba, and a dark red tumor sprang into view. The tumor was adherent to the abdominal wall, and in spite of all precautions its sack was slightly cut. Through this cut an almost clear, yellow fluid was discharged in a forcible stream. After the abdominal wound had been enlarged, it was found that the colon was stretched diagonally across the tumor, and its mesentery enfolded by the tumor to a large extent. The entire sack, therefore, was subserous. The mesenteric vessels, greatly distended, ran across the entire upper and forward portions of the tumor. The uterus lay flat against the tumor, and the course of the tube could be traced for about 12 centimetres on the tumor, its abdominal end, however, was lost. Next, an attempt was made to enucleate the tumor in spite of its subserous position, and to accomplish this a large portion of the mesentery of the colon had to be cut away, and a number of vessels tied. This revealed the facts, however, that in the first place the wall of the fœtal sac was uncommonly thin and friable, so that every endeavor to loosen the adhesions with the finger resulted in tearing it further; and in the second place, that the placenta was attached to that part of the fœtal sac which was closely adherent to the colon. Every attempt in this direction caused terrible bleeding, which rendered a continuance of such a course most dangerous. For these reasons the enucleation of the fœtal sac was abandoned. Now the sac was opened at the point which had already been cut, and a pulsating umbilical cord fell from the incision. In consequence of this the fœtus was speedily delivered and the cord ligated and cut. After a few efforts at resuscitation the child revived and began to cry. The position of the fœtus in the abdomen had been such that its head was pressed against the right rim of the pelvic bone, and reached somewhat down into the pelvis, while its breech was to the left under the arch of the ribs. After the removal of the child, a hæmorrhage from the fœtal-sack took place, which flooded the entire field of the operation in a moment, and nothing remained but to tampon the sac with iodoform gauze. The use of a very considerable quantity of gauze was necessitated before the hæmorrhage could be even in a measure controlled. The sac was now sewed to the abdominal wound. This procedure was most difficult, since the opening in the sac extended to the colon. and the uppermost stitch came close up to the bowel. The patient was put to bed almost pulseless, but the action of the heart soon became better, so that any immediate danger was not feared.

The child which had been brought into the world under such strange conditions was rather poorly developed. Its length was 42 centimetres, and its weight 1,880 grammes. It was interesting to note that there was a deep impression in the left parietal bone, corresponding to the place where fœtus had been pressed against the rim of the pelvis. Besides this there was a decided contraction of the right sterno-cleido-mastoid muscle.

The course of the case could not be called other than uneventful. After a few days there were decided symptoms of iodoform poisoning, in the form of a high degree of psychic excitement, which almost reached the extent of maniacal attacks. Apart from this a very frequent pulse and severe headache, and upon examination the urine was found to contain enormous quantities of iodine. In consequence of this the iodoform tampon was removed on the fifth day and replaced by a tampon of sterilized gauze. Now the patient's temperature began to rise for the next few days, and an increasingly disagreeable odor came from the sac. Since the placenta did not spontaneously loosen itself from the sac, its detachment was finally undertaken manually on the eleventh day after the operation. The procedure caused a most threatening hæmorrhage, which could only be checked with great difficulty by means of a new tampon. Several days later the tampon was cautiously removed, at which time there was no further hæmorrhage. Now, a systematic irrigation of the sac with antiseptic solutions was begun, after which it soon became smaller, and the wound was closed at the end of five weeks. The entire healing was not, however, complete until after the lapse of three months, owing to the necessity of a secondary abdominal suture at the upper angle of the wound. This was occasioned by the formation of a fæcal fistula, caused undoubtedly by the needle when the primary suture of the sac to the abdominal wall was made.

The child was fed by the bottle on sterilized milk, and thrived well under the influence of watchful care. For the first six weeks it was kept in a Crédés' "Warm-box"

or incubator, and later during the summer months was secured from loss of heat by warm clothing. In October, it had attained the weight of 3,200 grammes and a length of 49 centimetres. Unfortunately, after it left the clinic it acquired a gastro-intestinal catarrh, obviously from the lack of proper nourishment, and died in two weeks.

A study of the above two cases affords an ample opportunity for judging the remarkable differences of individual cases of extra-uterine pregnancy from an anatomical, clinical, and operative point of view.

I may sum the conclusions I have arrived at, from personal experience, in the following brief sentences:

(1) In well-developed cases of advanced uterine pregnancy, operative interference is indicated in all cases.

(2) In these cases a total extirpation of the fœtal sac should be aimed at, whereas a stitching of the sac to the abdominal wound should only be resorted to in cases of necessity.

(3) It is not advisable to delay the extirpation until the death of the fœtus, but to operate upon every case of extra-uterine pregnancy as early as possible.

CRUSHED FOOT—TUBERCULOUS DISEASE OF THE TIBIA—TUMOR OF THE FACE—SPINA BIFIDA.

By ROSWELL PARK, M. D.,
BUFFALO, N. Y.

Gentlemen: The patient, 24 years of age, was hurt yesterday by getting his foot caught between the bumpers of freight cars. He was taken in the ambulance to the Fitch Accident Hospital, an emergency dressing was applied to the foot and he was then brought here. He has been carried into the clinic-room so that I may make my first examination of him in your presence. There was quite an extensive laceration of the soft parts of the foot and the ambulance surgeon also diagnosed fracture of the tarsus. There was considerable oozing yesterday which necessitated the application of an elastic bandage outside of the emergency dressing. There is quite an extensive laceration over the outer side of the tarsus and the toes are not as warm as the rest of the foot. Still they are not as much discolored as I would expect them to be by this time if their circulation was entirely shut off, and I hardly anticipate gangrene of the toes. There is a large amount of swelling of the foot and with the blood-clot which has now had some twenty-four hours in which to form and which acts as a soft glue to hold the parts together, it may be that unless I disturb the fragments of bone considerably I shall get no crepitus. Now it is no object for me to disturb the process of healing simply to confirm another man's diagnosis unless it is necessary to correct a displacement or unless a change of treatment is contemplated. Steadying the posterior part of the foot and grasping the anterior, I make a slight swaying motion, endeavoring to elicit the sensation of crepitus, as felt by the fingers rather than causing any audible sound. I find no crepitus but inasmuch as the foot is in good position, the apparent protuberance on the plantar surface being merely a swelling of the soft parts, I do not think it justifiable to make any forcible movements. The injury was one by which fracture might easily have been induced, and there is every reason to think that there is fracture of one or more of the tarsal bones. The treatment of any fracture is restoration to the proper position and then physiological rest. The position does not seem to have been much disturbed here and physiological rest will be maintained by the antiseptic dressing and confinement to bed.

If to-day or later there occurs elevation of temperature and chill or excessive pain, or if redness of the skin of the entire foot and ankle or small red lines indicating phlebitis and periphlebitis are seen extending upward from the foot, I shall fear sepsis, and in that case the indication would be to anæsthetize the patient at once, to explore thoroughly and meet any indication that might arise, even the removal of the whole foot. There is no reason, however, to fear such a disastrous result in this case. I speak of it only as a possibility against which we must guard.

[The foot was dressed with iodoform ointment and powder and over that layers of bichloride gauze and cotton, the whole held on by a roller bandage. No untoward symptoms developed, and the patient in time recovered full use of the foot.]

TUBERCULAR DISEASE OF TIBIA.

Two weeks ago I chiseled out the lower end of this young man's tibia and allowed the opening to fill up with blood-clot. The case was one of osteo-sclerosis, a consolidating form of tuberculosis of bone, corresponding to fibroid phthisis in the lung. All active tubercular elements had probably been long ago strangulated out by the activity of the cells of the part. The boy has had some pain since the operation, but not nearly as much as he suffered before entering the hospital, and we are now about to dress the wound for the first time. We find here a

quantity of pus, or rather of puruloid material, for there is no reason to believe that this matter has any septic element in it, otherwise we should have had signs of a general septic condition, and there would be redness of the limb and red lines indicating the extension of infection by the lymphatics. No signs of such trouble are to be seen here. I now spray out the wound with a hydrogen peroxide solution and find perfectly healthy granulations. Yet there has not been the perfect organization of the blood-clot and incorporation of decalcified bone which I had hoped for. The question naturally comes up whether there was lack of precaution in shaving and disinfecting the field of operation or in the operation itself and the dressing. Certainly as far as is possible in human affairs, we observed every means of avoiding the entrance of micro-organisms, and the appearance of the wound was not such as to lead me to think that any true septic process had taken place. A surgeon is often in a quandary to know just when to remove a dressing. When a wound heals perfectly by first intention under one dressing—as you have often seen illustrated in these clinics—he says, "I did right in not touching the dressing before." When it does not heal so nicely he says, "I ought to have dressed the case sooner."

But although there has not been the ideally perfect result hoped for, this large wound has been more than half filled up with granulations, there has been no sepsis, the pain has been relieved, and there is the surety of the complete cure of the condition subsequently by the growth of these granulation. In short, neither have we nor has the patient anything to complain of. I will now reapply an antiseptic dressing, and the leg will have to be dressed oftener for a few days.

TUMOR OF THE FACE.

This young man, seventeen years of age, shows a scar across the cheek where he was kicked with the calk of a horse's shoe three years ago. The wound healed readily, but a year later the parts underneath the scar began to swell, and he comes to me now with a protrusion of that part of the face by what is evidently some neoplasm. This new growth has lasted two years, has enlarged very slowly, has presented at no time any of the signs of inflammatory action, so that we can practically leave out of consideration all thought of abscess, even of cold abscess. On further examination I fine the nostril free, and the tumor which is very soft and fluctuating is movable over the anterior wall of the antrum of Highmore. At first glance, the tumor looks like a protruding growth from the antrum, but if it came from the antrum and had grown so far into the mouth, it would also protrude into the nostril, and obstruct breathing. It is outside the bone and beneath the skin. The diagnosis, then, is narrowed down to fatty tumor and cyst. It is an unusual location for a lipoma, and while I have not tapped it, I presume it is a cyst, but proceeding from exactly what place, I do not know. It does not necessarily follow that it is the result of the kick received the year before, but previous history of injury is always suspicious, and one naturally ascribes such a lesion to the consequence of a blow. Probably we are often in error in so doing.

But the consideration of the etiology of the tumor is comparatively trivial for its presence and the indication for its removal are patent facts. I could go through the external scar and leave not much greater disfigurement than already exists but I contemplate attacking the growth from within the mouth. This method is a little harder for the operator but better on account of the looks of the patient. I find also a scar on the check which shows that the old laceration must have extended entirely through into the mouth. A quantity of thick mucoid material exudes from the opening which I have made into the cyst. I now place my finger in the cyst cavity and tear out as much of the lining membrane as I can, completing the removal with the forceps. It is always important to dissect away the cyst wall in order that the cavity may be closed completely and permanently by the healing process, and the tougher the membrane the greater the necessity of removing it. The cyst, you see, was nearly as large as a hen's egg.

SPINA CIFIDA.

Here is a tumor, evidently congenital, as the history confirms it to be, occurring in the middle line of the back of a small child and bearing marks of its dermoid if not teratomatous character in the growth of hair about it. It is movable and from the appearance we can not say whether it is a spina bifida or whether it is entirely outside the spinal canal. Besides spina bifida proper, which implies a congenital defect in the laminæ of the vertebræ, there is a similar condition known as hydro-rachitic cyst, which means a cyst communicating indirectly by a small passage, perhaps quite long, with the spinal canal. This passage may go between the vertebræ and does not necessarily imply

any trouble with the development of the spinal column. The mother says that whenever the child gets irritated and cries—which produces some cerebral congestion—this tumor enlarges, as if with the fullness of the cerebral circulation, fluid was forced out of the cerebro-spinal cavity and into this tumor. This lends probability to the supposition that it is a spina bifida or hydro-rachitic cyst.

The hair grows widely around the tumor and for scientific purposes I should like to retain the hair on the specimen, but the child's interests take precedence and we will therefore shave the hair off as a part of our aseptic precautions. The child will probably always have more or less of a dorsal beard. The cyst I find by palpation to be very thin walled and it is quite unlikely that the boy can go through the terrors and pleasures of child-life without its being ruptured, and if it connects with the spinal canal as it seems to, rupture would probably mean death within forty-eight hours.

On exposing the cyst wall, I find that the tumor has a pedicle about an eighth of an inch in diameter and I will tie this tightly before opening the cyst and in order to preserve the contour of the sac till we open it. I will tie another ligature a little higher up and cut between. After removing the cyst, there seems to be no leakage from the pedicle. This is an unusually favorable case for operation and I have closed up the external opening tightly without drainage.

EXTIRPATION OF A TUBERCULOUS KIDNEY.

Schuchardt(*Deutsche medicin. Wochenschr.*, Sept. 3, 1891), at the Congress of German Surgeons, reported a case of cystitis in the course of which pyonephrosis developed. Incision afforded but temporary relief. Tuberculosis was suspected, and confirmed by reaction to tuberculin. Other treatment failing, the kidney was removed. Following the operation the excretion of urine was diminished, uremic symptoms appeared, and on the fifth day the urine was suppressed. Death took place on the ninth day. At the autopsy the pelvis of the kidney was found occupied by calculi; the renal structure was almost entirely wanting. Histologically, no changes were found that could be ascribed to the action of tuberculin; the giant-cells were in places disintegrated by the invasion of leucocytes; but bacilli were still to be found. Necrosis of the epithelium of the remaining kidney was the probable cause of the development of uremia.

COMMUNICATIONS.

THE USE OF GELATINE DISCS IN THE EYE.*

By JOHN S. STEWART, M. D.,
OPHTHALMIC SURGEON TO THE PHILADELPHIA LYING-IN CHARITY.

Some excuse, perhaps, may be needed for bringing before this Society a subject which can be of practical interest to specialists of one department only; but it has occurred to me that a very brief account of one of the methods of applying medicaments to the eye, which, in my hands at least, has proven highly satisfactory, may be not altogether devoid of interest even to those engaged in other lines of work. I refer to the use of medicated gelatine discs, and in the present instance will consider only the advantages of applying homatropine and cocaine to the eye by this means. Four years ago, in an article on the subject "Homatropine," published in *The Medicale News*,† I called attention to the fact of having frequently observed an irritant action exerted on the deep structures of the eye by repeated applications of a watery solution of hydrobromate of homatropine. At that time it was my belief that this irritation was the principal cause why ametropia cannot be accurately estimated in very many cases where homatropine has been employed, and a considerable experience since in the use of watery solutions of the drug tends only to confirm this opinion. That irritation is produced in every instance by this method of practice, I do not pretend to say; but I am convinced that in all cases where there has been considerable and long-continued eye-strain, from efforts to overcome particularly aggravating forms of refractive error, or where chorio-retinal irritation, due to other causes, exists, the homatropine as ordinarily used very often adds to the intra-ocular disturbance, and thereby interferes with attainment of the object for which it was employed, viz.: the accurate estimation of the refraction of the eye.

Another objection which I have to the use of watery solutions of this drug is that a large proportion of the effort is expended on the nasal and pharyngeal mucous tract rather than on the eye, as intended. There is no doubt in my mind that both the irritant effects on the eye and the, at least, unpleasant ones of the nose and throat are directly due to the necessarily strong solutions employed

*Read before the Philadelphia County Medical Society, March 23d, 1892.

†March 3, 1888.

—ranging, as far as I have been able to learn, from eight to twenty-four grains to the fluid-ounce—instilled in most intances a number of times within an hour.

It is claimed that medicated gelatine discs for ophthalmic use were first made in 1863 by Savory & Moore, of London; but, strangely enough, they have never been extensively used. About five months ago I began to try some of those made at the suggestion of Dr. C. A. Wood, of Chicago, by Messrs. Wyeth & Brother, of this city, and almost ever since, when I have had occasion to use homatropine alone or combined with cocaine for the purpose of refractive work, I have much preferred these discs to the watery solutions formerly used by myself.

On first thought it may seem unlikely that a single disc, containing $\frac{1}{30}$ grain each of homatropine and cocaine, could exert sufficient influence on the accommodative power; but I have, in most instances at least, found as nearly complete paralysis of accommodation as I have ever been able to obtain with repeated instillations of 2 and 3 per cent. solutions of homatropine. The reason is not hard to discover. Absorption of the drug by the tissues of the eye takes place about as rapidly as the drug itself can be liberated by the dissolving of the gelatine; but when a drop of solution has been instilled, a large proportion necessarily escapes with the tears, or, if it does not get away so quickly, is quite likely to produce in sensitive eyes the chorio-retinal irritation which so often interferes with obtaining to results for which the drug was used.

Very few of my patients who had these discs in their eyes could detect any effect whatever in the nose or throat, and in these few instances the information was obtained only by questioning the patients on the subject.

In my practice at the present time, in all eyes suitable for the use of homatropine and requiring its use for the purpose of refraction, I am making use of discs containing $\frac{1}{30}$ grain each of homatropine and cocaine—either of hydrobromate and muriate respectively, or the alkaloid of each. I have found it an advantage, but not always a necessity, in the case of most of my patients under twenty-five years of age, to insert a second disc of homatropine only ($\frac{1}{30}$ grain) in each eye as soon as the first is entirely dissolved—usually in about ten minutes. A small camel's-hair brush moistened serves conveniently to convey the disc to the eye, and although it has been recommended to place he disc against the scleral conjunctiva—in the grasp of the lower lid—I much prefer raising the upper lid and inserting the disc beneath it, immediately above the outer canthus, then directing the patient to keep the lids lightly closed as in sleep, and to avoid winking until the discs are dissolved.

It has been urged against the use of the gelatine discs that the lids and eyes are thereby rendered very sticky and uncomfortable.

My patients have not complained of this; but I think the annoyance was escaped, in a large measure at least, by strictly following my injunction about keeping the eyes closed.

As to the reputed advantage of the combination of cocaine with homatropine, I have little to say. It is claimed, of course, that homatropine combined with cocaine dilates the pupil and paralyzes the accommodation more rapidly and effectively than homatropine alone, and that these results are more permanent. This seems usually to be the case; but cocaine is used by me in these cases because of the quieting effect it produces on most eyes, thus tending, in some measure at least, to overcome the irritant effect of homatropine, and at the same time to facilitate the measurement of the ametropia.

In conclusion, it should be added that on several occasions I have used the English preparation of Savory & Moore, of London; but there is no hesitation on my part in expressing a preference for the Wyeth discs.—(*For discussion, see Society Reports.*)

THE TREATMENT OF PNEUMONIA.

In the *Edinbury Medical Journal*, 1891, No. clxxxvii. p. 393, Dr. George W. Balfour presents an instructive paper advocating the use of chloral combined with digitalis; the avoidance of preliminary purgation; the moderate use of digitalis to prevent cardiac collapse and as an antipyretic, with chloral to combat the insomnia, pain, and cough. The precise method is Liebreich's chloral—none other being regarded by the writer as safe—dissolved in infusion of digitalis. For an adult twenty grains of chloral dissolved in half an ounce of infusion of digitalis, in four hours ten grains in the same amount of infusion, and so continued until the temperature falls to the normal, when it is replaced by an appropriate tonic. A jacket poultice is a useful adjuvant, which may be, however, replaced by a sheet of cotton-wool. Suitable diet cannot be dispensed with.

SOME CASES OF OBSTRUCTIVE DISEASE OF THE LACHRYMAL PASSAGES AND THE ASSOCIATED INTRA-NASAL LESIONS.*

By G. E. de SCHWEINITZ, M.D.,

Professor of Ophthalmology in the Philadelphia Polyclinic; Lecturer on Medical Ophthalmoscopy, University of Pennsylvania; Surgeon to the Philadelphia Hospital, etc.

The intimate relationship between diseases of the lachrymal apparatus—that is, of the drainage system of the eye—and various types of inflammatory changes in the nasal mucous membrane is an old story. Indeed, the close association of ocular and naso-pharyngeal disease is not limited to these conditions. The great majority of phlyctenular ophthalmias depend upon type of rhinitis, and are often the direct outcome of adenoid growths in the pharynx. Many obscure symptoms which we are wont to describe under the general term asthenopia, have been shown to depend upon intra-nasal disease, and a variety of orbital, ocular, and post-ocular pains are frequently "referred pains;" that is, their origin is from some lesion within the nasal cavity, the frontal sinus, ethmoid cells, or antrum of Highmore. In fact, as Harrison Allen has remarked, a good deal of the success of treatment depends upon a proper attention "to the commonality of the various parts of the cephalic mucous membrane."

The following cases are reported, not because they illustrate new points, but because they emphasize some old ones, and still more because they emphasize that the cure of obstructive lachrymal disease is materially facilitated not merely by the ordinary measures adopted for rendering the passages patent, in association with what may be called routine intra-nasal treatment (for I take it no one attempts to treat lachrymal disease without due attention to the nasal mucous membrane), but that more radical measures are frequently of value when applied to the nasal chambers and the vault of the pharynx, which in the vast majority of cases are the regions primarily affected.

Case I. *Purulent dacryocystis; traces of old rhinitis and abnormal shape of the lower turbinated bone.*—D. D., a boy aged seven years, reported for treatment November 3, 1890. Three years ago pus began to exude from the right punctum lachrymale, and in spite of treatment this condition has continued ever since. The boy was healthy in other respects; he had never suffered from measles or scarlet fever; was free from the evidence of inherited syphilis, and sustained no injury. His voice was slightly nasal in tone.

The lower caniculus was slit, and a firm stricture was found at the beginning of the nasal duct. The probe was not forced; neither was the stricture incised.

The patient was referred to Dr. Alexander MacCoy for nasal examination, who reported as follows: "The right nostril shows an abnormal shape of the lower turbinated bone, also some evidence of a severe rhinitis during the past. I believe that the position and form of the lower turbinated body have had much to do with the disease of the duct on account of the obstruction to its entrance at its lower portion into the nasal chamber. The boy also has a pharyngeal tonsil, which obstructs the posterior nares somewhat." Dr. MacCoy undertook the treatment of the nasal condition, and after a few days the stricture was incised, the probe passed, aud the nasal treatment instituted. After the intra-nasal obstruction was removed the epiphora ceased, and has not reappeared.

I have referred to this case in a paper on the use of pyoktanin in dacryocystitis (*University Medical Magazine*, vol. iii. p. 181), and may repeat that my colleague, Dr. Gould, as well as myself, has had favorable effects from this drug in the treatment of unhealthy lachrymal secretions.

The case is now utilized, however, to illustrate what seems to me a very important point to which Dr. MacCoy calls attention in his report, namely, that although the stricture of the duct, which in this case existed high up, was penetrated, and although the fluids and the probe passed readily, the epiphora continued because of the malposition of the turbinated bone. Indeed, this obstruction sometimes exists only in the form of a small flap of mucous membrane, which closes the entrance of the duct into the inferior meatus very much as a valve would do. This effectually prevents the drainage of the eye, and unless it is removed good results will not follow. In this particular instance it was very easy to see the obstruction by first passing a probe and then exposing the entrance of the duct into the meatus by means of a nasal speculum—a slight precaution which will often lead to the discovery of the cause of a persistent overflow of tears in spite of apparent permeability of the passages.

*Read before the Philadelphia County Medical Society, March 23d, 1892.

Case II. *Catarrhal dacryocystitis; bands of adhesion from the inferior turbinated body to the septum.*—Ella H., aged twenty-eight years, reported for treatment at the Philadel- Polyclinic, October 24, 1891, on account of an inflammation of the right eye, which had existed for several days. There was a small abscess at the inner margin of the lower lid, with a fistulous communication into the lachrymal sac. A free muco-purulent secretion distended the sac in the form of an ordinary mucocele. The canaliculus had been slit at some previous time, but a probe did not pass readily.

She was referred to the throat department, and examined by Drs. Arthur Watson and Walter Freeman, who reported as follows: "Atrophy of both inferior turbinates; unable to obtain a posterior view; former ulceration of the posterior wall of the pharynx; bands of adhesion from the inferior turbinates to the septum; also one from middle turbinate to the septum on the right side."

Even in absence of definite history the pharyngeal condition seemed to indicate syphilis. The patient was ordered an astringent lotion, given potassium iodide and bichloride of mercury, and referred to the throat department for treatment. In January of this year an operation was made on the lower turbinated bone, and the condition has improved without the passage of probes, the secretion and epiphora having materially lessened.*

This case, it seems, illustrates the ordinary intra-nasal lesions which were evidently at the bottom of the lachrymal trouble, and is further interesting because these lesions gave confirmatory evidence of the syphilitic condition, so much so that relief was facilitated by the proper constitutional remedies.

Case III. *Lachrymal abscess; spur on the septum opposite the middle turbinated bone; chronic pharyngitis.*—Sarah S., aged forty-five years, reported for treatment at the Philadelphia Polyclinic, November 24, 1891. In April, 1891, epiphora began in the left eye, for which she seems to have undergone no treatment. It continued until about one week ago, when suppuration of the lachrymal sac took place. When she presented herself there was a marked lachrymal abscess. The pus was evacuated by an external incision, the sac freely irrigated with an antiseptic fluid, and the patient referred to Drs. Watson and Freeman for an examination.

They reported as follows: "On the left side there is a spur on the septum opposite the middle turbinated bone; also hypertrophy of the tissues. The turbinates are small. There is chronic pharyngitis, a thick phlegm covering the tissues."

Unfortunately this patient has failed to report with any regularity, and the ultimate result cannot be given. This example illustrates the course of so many of these cases, namely, a chronic pharyngitis and hypertrophy and inflammation of the intra-nasal mucous membrane; involvement of the lachrymo-nasal duct; epiphora, owing to an obstruction primarily from swelling of the mucous membrane, and later from the formation of a positive stricture. Under the influence of the pressure and of the stricture, the fluids of the conjunctival sac are not drained, but distending the lachrymal sac, become infective, an abscess forms, and the condition which has been described results.

Case IV. *Epiphora; atrophic catarrh.*—Jane C., aged sixty years, reported for treatment at the Philadelphia Polyclinic, November 14, 1891, complaining of pain in her eyes, constant epiphora, and inability to read on this account. There was considerable hypermetropia and some astigmatism, and, as epiphora is frequently caused by the strain of uncorrected ametropia, proper glasses were ordered, but the overflow of tears continued. Both canaliculi were then slit. There was narrowing of the ducts, but no stricture, and probe and fluids passed readily. The epiphora improved, but did not disappear.

She was referred to the throat department, and the following report was received: "There is an atrophic condition on both sides, and a spur on the septum on the right side near the opening of the lachrymal duct, but it does not interfere. The closure is probably due to contraction from atrophic changes."

This is a good exrmple of a very common condition, most frequent in elderly people, where there is neither disease of the sac, stricture of the duct, nor pressure from a spur or hypertrophy of the turbinated bodies, but where the obstruction depends upon contraction from atrophic changes.

Case V. *Phlegmonous dacryocystitis; deflection of the septum; spur on the left side pressing on the inferior turbinated bone.*—Matthew L., aged twenty-seven years, presented himself for treatment on account of an extensive lachrymal abscess with a small opening and widespread infiltration of the tissues, producing a large swelling involving the lower lid and cheek. The abscess was incised, the pus cavity freely washed out, and an antiseptic dressing applied. In a day or

* Recently there has been a relapse in this case. Attention to treatment has not been regular.

two the swelling had subsided, and nothing remained but a slight brawniness of the tissues and a fistulous opening at the point of incision. The canaliculus was slit, but all efforts to introduce the probe prove futile. The patient had been much exposed to weather; had a history of an old injury, but denied syphilis. The obstruction to the tear passages had existed since the early fall.

He was referred to the throat department, and the following report was received: "The septum is irregularly deviated in front; there is a spur on the left side pressing on the inferior tubinated body, which also contains an ulcer in its anterior portion."

He was warned that "catching cold," which would increase the nasal obstruction, would certainly bring about a relapse of the abscess. He went to work, however, and returned a few days afterward with all of the lesions previously described in a very much more aggravated state. The same treatment was instituted, and he was again referred to the throat department, and on the 23d of February the hypertrophy on the left side was removed. On the same day a probe was passed, and since this time its passage has been repeated. Epiphora still continues, but is decreasing day by day.

This example illustrates the mechanism of relapse in many of the tear-passage cases, in this instance producing a very serious phlegmonous inflammation. Under treatment and rest sufficient drainage takes place to produce amelioration of the symptoms; then swelling from congestion, owing to exposure, is added to the organic obstruction already present, producing complete closure with an exacerbation such as has been detailed.

Case VI. *Stricture of the nasal duct; moderate hypertrophy of the inferior turbinated on the left side and a spur on the right side.*—Bridget R., aged fifty years, applied for treatment to the throat department of the Philadelphia Polyclinic, and the following lesions were found: A moderate amount of hypertrophy of the left inferior turbinated near the nasal duct, and a spur on the septum of the right side close to but not obstructing the opening of the duct. With these lesions there were epiphora, most marked in O. D., and slight lachrymal conjunctivitis. She had not been able for a number of months to use her eyes with any comfort.

She was referred by Drs. Watson and Freeman to the eye department. The canaliculi were slit, and a stricture was found at the mouth of each sac. A No. 2 Bowman's probe was passed without difficulty.

It is evident that although there were lesions in the nasal passages, they were not obstructing the duct, but under the influence of the chronic nasal inflammation a stricture had formed in the lachrymal canal.

Case VII. *Epiphora from swelling of the mucous membrane of the lachrymo-nasal duct; atrophic rhinitis.*—A. K., an unmarried woman, aged twenty-six years, was referred to me by Dr. Ralph W. Seiss, on account of epiphora of the right eye, which had persisted for some time in spite of the nasal treatment. There was no swelling of the lachrymal sac; no catarrhal or purulent secretion, but simply an overflow of tears. The general health was good, the eyes not far from emmetropic, and there was neither asthenopia nor headache.

Dr. Seiss has kindly furnished the following report of the nasal lesions: "Atrophic rhinitis presenting the ordinary appearances of tissue-destruction, combined with some odor and much secondary laryngo-bronchitis."

The canaliculus was slit, and a No. 3 Bowman's probe was passed without meeting a stricture, but with a resistance to its passage which is characteristic of obstruction from swelling of the mucous membrane. After the passage of this probe the duct was irrigated on several successive days with a solution of boracic acid and common salt without, however, passing the canula into the duct. The fluid trickled readily through the nose. The epiphora stopped after a few treatments, and has never returned, although many months have gone by since she originally reported.

The patient represents a common class of cases of epiphora associated with chronic inflammation of the naso-pharynx. A somewhat similar inflammation occurs in the nasal duct, but does not produce a true stricture; the occlusion is from swelling, not from cicatricial changes. In many cases it is sufficient to do what was performed in this case; in others even milder measures suffice. Above all things, this is an example of a class of cases the successful treatment of which I have learned especially from Dr. Risley, by obeying the principle which he was wont to instil not to be too ready to pass probes and canulas, lest their introduction scrape away some of the mucous membrane, and really do more harm than good. It is unnecessary to do more than medicate the swollen mucous membrane with any solution that is suitable; I like boracic acid and common salt very much.

Many more cases might be quoted, but these seven representatives of various classes

are sufficient to illustrate the points which I desire to make:

1. A large class of cases exists characterized chiefly by epiphora without catarrhal or purulent secretion, in which the obstruction in the lachrymo-nasal duct depends upon swelling of its mucous membrane, and not upon true stricture. The primary origin of these cases in the great majority of instances is a chronic or subacute post-nasal catarrh. The evident indication is the treatment of the latter condition and the medication of the swollen mucous membrane of the lachrymo-nasal duct, so that it may regain as nearly as possible its natural condition, which it will do without much instrumental interference—an interference that may of itself, if unskilfully performed, be the cause of a cicatrizing band that never originally existed. Case VII. of the series illustrates this class.

2. The life history, if I may so express myself, of many cases of obstructive disease of the lachrymo-nasal duct and the formation of a lachrymal abscess is illustrated by Cases III. and IV. First, a chronic pharyngitis occurs; later, hypertrophy and inflammation of the intra-nasal mucous membrane, followed by swelling of the lining tissue of the lachrymal duct. Gradually cicatricial changes arise, and a true stricture is formed. The drainage of the conjunctival cul-de-sac ceases; the micrococci natural to the part, and those which readily find access to this region, permeate the contents of the lachrymal sac because this can no longer be emptied; the pathogenic microörganisms exercise their true function, and suppuration occurs.

3. A number of cases develop, chiefly in old people, in which there is epiphora, again without the presence of pus or muco-pus, depending upon obstruction in the lachrymal duct from atrophic changes, the whole being part of a similar atrophic process in the intra-nasal passages, and generally described under the term atrophic catarrh. The obstruction in these instances is not from swelling, not from stricture, but from contraction. Case IV. of the series is an example.

4. A very common cause of an exacerbation of lachrymal disease is due to the presence of a hypertrophic turbinated body, or similar intra-nasal obstruction, which under treatment has gradually subsided, but which, owing to exposure, swells up again, and exercises its obstructing influence. At once there is occlusion of the lachrymal passages and recrudescence of the symptoms. The very serious nature of such cases is illustrated in case V. of the series.

5. In every case of local disease the physician should be mindful of constitutional causes: the value of confirmatory evidence by pharyngeal and intra-nasal examination is illustrated in Case II., an example of constitutional syphilis. Local treatment may be very necessary; local treatment without general medication is ineffectual.

6. Finally, I come to the class of cases in which there exists an obstruction at the intra-nasal end of the duct (it may be trivial), permeable by the fluids used in a syringe, but an impassable barrier to the outflow of tears. Even the slightest obstructions, under these circumstances, may defeat the most classical treatment of lachrymal disease. The ready detection of such a lesion is illustrated in Case I. of the series.

It has not been my intention this evening to refer to what are the best means of treating lachrymal disease, except in so far as these are implied by the descriptions of the lesions which existed in the examples I have reported. Whether we believe that small or large probes should be passed; whether we class ourselves with those who believe that the probes should not be used at all; whether we are the advocates of this or that antiseptic and astringent fluid; whether we think that strictures should be incised or should not be incised, or whether we believe in the permanent wearing of styles or canulas, it is evident that the rational treatment of certain types of obstructive lachrymo-nasal disease must also include not alone the ordinary intra-nasal treatment with sprays and powders, but a systematic and thorough examination of the naso-pharynx, and, if necessary, the best operative interference known to intra-nasal surgery.—(*For discussion see Society Reports.*)

ANTIPYRIN IN HEMERALOPIA.

Hemeralopia, or night blindness, is an inability to see after sunset, during the night or during the day if the locality is dark. This affection which accompanies pigmentary retinitis, begins usually about the age of 18 years, and generally attacks all members of the same family; it is incurable. Grandclement has discovered by accident the efficacy of hypdoermatic injections of antipyrin in these cases; he employed them in three patients affected with the symptomatic hemeralopia of pigmentary retinitis, after a treatment with antipyrin. The three patients who had been compelled to give up their occupations, were soon able to go back and resume their work.—*Annales d'Oculistique*, 1891, p. 232.

THE AFTER TREATMENT IN ABDOMINAL SECTION.

By J. A. PRINCE, M. D.,
SPRINGFIELD, ILL.

It is not my intention in this paper to consider any routine practice in these cases, but a few of the more important symptoms that may arise.

Though the majority of these cases recover with an uneventful convalescence, cases are now and then met with which tax the resources of the operator to the utmost and may even require a secondary operation for the relief of some urgent symptom.

Among the more important complications that may arise that may demand active interference may be mentioned in the order in which they will appear; shock, secondary hæmorrhage, the various forms of sepsis, and obstruction of the bowels.

Since the introduction of the aseptic methods in conducting operations, septic complications are not so frequently met as some others, notably, obstruction of the bowels.

In a recent paper read before the New York Obstetrical Society by Dr. Hanks, of New York, he estimates the mortality from this latter cause at the enormous rate of 50 per cent. With the old form of treatment, that of locking up the bowels with opium for a week following the operation, this result would not be surprising, but with the forms of treatment employed to-day, where the bowels are opened early and kept open, such a figure seems to me to be too high.

When these operations are performed in the general hospital the question of securing a capable nurse need not be considered, but these operations are being done, more now than ever before, by men who do not have hospitals to which they can send their patients, and commonly the patients are too poor to afford the luxury of a trained nurse even if one were obtainable. It remains for the physician to secure some one who has had some experience in nursing, and carefully instruct her as the case progresses.

A young woman should be preferred, one who can learn quickly and can be depended upon to carry out instructions to the letter. A graduated nurse, being well posted in all the branches of the medical sciences, sometimes becomes liable to do a little prescribing on her own account because she thinks a certain thing is indicated.

It is probably for this failing, and the fact that they are not so easily moulded into your ways of nursing, that most operators prefer nurses who are more or less ignorant of materia medica and therapeutics, and have gained what knowledge they possess by practical work at the bedside.

When the operation is done in the hospital there is the additional advantage of the supervision of the house surgeon, while if done at the home of the patient without the benefits to be derived from trained nurses, the surgeon must give the after treatment his own supervision and care.

As the course and termination of these cases is dependent upon modes of operating, it will be necessary to consider some points in the technique of the operation bofore proceeding with the subject of the after treatment.

It is generally considered that the toilet of the peritoneum is one of the most important steps in the operation, but, while admitting its importance, I think many lives are needlessly lost from shock due to the increased time spent in thoroughly cleansing the peritoneal cavity by means of flushing.

It is a question in my mind whether flushing has any advantage over simple sponging with sterilized sponges or gauze.

Blood clots and the materials which escape from the cysts adhere to the viscera very tenaciously, and, while flushing readily removes the free blood, it removes the clots with difficulty; they adhere, however, readily to the sponge or piece of gauze, and can be easily and quickly removed.

The fluids used in the flushing have no antiseptic properties usually, being weak solutions of boric acid or sterilized water, and are used simple for their mechanical effect in removing the foreign materials.

The care of the intestines during the operation has a very important bearing upon the after treatment. They should be subjected to as little injury and exposure as possible. I think it is the opinion of most operators that the intestines should be retained in the abdomen, if possible, and should much gaseous distention be present, it is better practice to puncture and let the gas escape than to take the intestines out of the cavity. Some traumatic peritonitis, usually localized, follows the operation as a rule, and accompanying it is the effusion of more or less plastic lymph rendering the coats of the intestines sticky and necessarily limiting the movements; where adhesions occur the motions are prevented entirely.

If anything could be introduced into the peritoneal cavity which would facilitate the free movements of the intestines and prevent the effusion and organization of the lymph many cases of bowel occlusion might be pre-

vented, Boroglyceride has been advocated largely for this purpose, with the additional advantages of its antiseptic properties. But it was to be introduced, subsequent to the operation, through the drainage tube, and a little at a time. As the immediate space about the drainage tube is soon shut off from the general cavity, I think it is evident that it would act more efficiently if introduced at the time of the operation.

In Dr. Martin's Private Hospital in Berlin, olive oil is extensively used for this purpose. It is the practice there to saturate a large flat sponge with the oil and introduce it over the intestines while the deep sutures are being placed in the abdominal walls. During the manipulations much of the oil escapes and forms an oily coating over the viscera, the free oil accumulating at the bot- of the pelvis, where it remains as a reserve supply. How long the oil remains in the cavity before being absorbed I do not know. I have seen it coat the surface of the blood, removed through the drainage tube, as late as the end of the second day.

If several ounces were introduced I should think enough might remain to prevent adhesions forming. Olive oil is not an antiseptic agent, that I am aware of, but it is a medium in which germs do not thrive.

The subject of drainage is such a discussed one, and the profession are about equally divided on the subject. About as good results are obtained by those who do not drain as those who do. The use of the drain complicates the after treatment somewhat, but if much oozing is expected it is better to be on the safe side and have some outlet provided for the escape.

The effused material might safely be gotten rid of through natural channels, especially when aided by the early use of cathartics to stimulate the osmotic flow outward through the intestines.

In an uncomplicated case the treatment will be nothing more than good nursing.

The first symptoms to require attention, if the operation has been more than usually severe, or has consumed much time, will be shock. It has been my observation that shock is more directly influenced by the length of time consumed in the operation than by any other factor.

In my father's practice time was sacrificed to thoroughness and the observations of many details, and nearly all cases manifested some symptoms of shock. It was successfully combated, however, in most cases by the aid of hot bottles and the administration of stimulating injections of whiskey and digitalis.

During the last year of his practice he experimented largely with oxygen, administered by the rectum, to promote reaction, with very good results, the absorption of the gas causing an increase in the volume of the pulse almost instantly, and sensibly shortening the period of depression.

In a large number of operations witnessed in Dr. Martin's clinic last summer, I noticed that he rarely had shock to deal with, no depression of temperature being shown on the charts. This result was not because there were no difficult cases met with, because many were extremely complicated, but because of the rapidity with which he operated. He rarely exceeded fifteen or twenty minutes, even in the most difficult cases, while simple ovariotomies were completed in from seven to ten minutes with no apparent effort to hurry the operation.

It may be of interest to some to have a short description of his methods. In the first place, a glance at Dr. Martin would never give one the idea that he was so skillful a gynæcologist, as he is a man of great size with large fleshy hands and an enormous abdomen. Through some accident he lost the use of one eye, and in order to see an object closely he is obliged to turn his head slightly; but with these apparent defects he is a most skillful diagnostician and operator.

Only second to Dr. Martin in efficiency and skill is his invaluable assistant, Frau Horn.

All the abdominal operations are done in a small room especially devoted to this work. Everything is kept scrupulously clean. The patient is placed upon a small table made of iron and devised for this work by Frau Horn. The top is of iron slats, and the middle ones are hinged and drop down to facilitate the application of the dressings. The table is just long enough to support the patient's body from the buttocks to the head.

Dr. Martin sits at the foot of the table, between the thighs of the patient, which are supported across his knees. His chief assistant sits on the right side of the patient, and ties all the sutures as they are taken. Frau Horn has entire charge of all the instruments, dressings, etc. The primary incision is made large enough to admit the entire hand of the operator, and seldom has to be enlarged even to admit the escape of very large tumors.

No attention is paid to hæmorrhage from the incision, the peritoneum being opened at once, as he considers the dangers from a prolonged operation greater than those which might occur from the escape of a little blood

into the peritoneal cavity. It surely must be because of his great speed in operating that shock is so seldom seen in his hospital.

The vomiting so rarely absent in these cases, is relieved more surely by time than by any medication. Since Tait has introduced the early use of small doses of sulphate of magnesia in these, it has been found that some cases of nausea are relieved by it. I do not think it increases it in any case.

The bowels should be opened early and kept open, and for this purpose there is nothing better than the remedy we have just spoken of. I have had very good success with it in dessert-spoonful doses of a saturated solution repeated every hour from six to eight hours, followed, if necessary, by a small enema containing a little of the salt.

The treatment of secondary hæmorrhage is, of course, to secure the bleeding point as soon as possible, but before subjecting the patient to the risk attending a secondary operation, all other possible causes for the symptoms should be excluded. Poisoning from the absorption of carbolic acid has been known to produce almost identical symptoms. The discoloration of the urine in the poisoning from carbolic acid, will, however, differentiate it.

Sepsis is the most surely fatal of all the complications, as there is no form of treatment which seems to influence the result in well established cases. Secondary laparotomy, with thorough flushing and drainage, offers the best results, but even by these means comparatively few cases recover.

The administration of remedies to subdue the high temperature, the use of ice bag, cold coil, stimulants, etc., seem to have no influence whatever over the final result.

The subject of bowel obstruction has of late received a large share of attention, and as Dr. Hanks has placed the mortality from this cause at so high a figure, it is an all important one. The symptoms usually appear from the third day on, and consist primarily in the inability to obtain a movement of the bowels, very soon followed by vomiting, which soon becomes excessive, with pain and distention of the abdomen. These symptoms may soon be followed by sinking and collapse.

It is is very common for symptoms of obstruction to come on, which may look very grave for a time, but the patient recovers without an operation. It is for this reason principally that operations are as a rule put off until too late, until the symptoms of sinking appear, when an operation is useless. With advancement in our knowledge of diagnosis in bowel obstruction operative measures for relief will be resorted to earlier and with much better chances for success.

An instrument known as the rectal obturator, devised by my father, for giving forced enemas, may prove successful in overcoming the obstruction in many incipient cases, but the continued use of such means exhausts the patient, and makes the chances for success much less if an operation is eventually required.

Should the obstruction be due to paralysis of the intestines, in some cases their tonicity may be restored by massage of the abdomen continued with galvanism.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting March 23, 1892, President John B. Roberts in the Chair.

Dr. John S. Stewart read a paper entitled "The use of Gelatine Discs in the Eye." (See page 686.)

DISCUSSION.

Dr. Samuel D. Risley: I am very glad that Dr. Stewart has given us his experience in the use of the gelatine discs. I have used them but very little, but this limited experience has not afforded me sufficient encouragement to abandon the use of carefully prepared neutral solutions of the mydriatics. The discs in which the cocaine is combined with homatropine, I have found invariably cause severe irritation, as the cocaine solutions are likely to do, and that the attendant profuse lachrymation is liable to wash away the homatropine before absoption can take place. I have not noticed any gluing of the eye by the dissolved gelatine. The obvious intention in the use of the disc is to secure some rapid means of paralyzing the accommodation, for the purpose of correcting errors of refraction. It is possible that in a certain group of cases, without much retino-choroidal irritation, that this means may be sufficient, as was demonstrated with regard to the use of homatropine in 1881. But there is a much larger group of patients, with well-marked retino-choroidal disturbance the result of eye-strain, in which it is essential to have the therapeutic results of prolonged mydriasis. In these patients the more persistent mydriatics are needed. I have tried to administer these in the gelatine disc again and

again, but have always come back to the solution as more satisfactory.

Dr. Louis J. Lautenbach: The gelatine discs of which Dr. Stewart has spoken have been used by me for the past few months. It has seemed rather strange that the use of a one-fiftieth ($\frac{1}{50}$) of a grain of homatropine, or at most of two such applications, that the results obtained were practically the same as when from four to eight times this quantity were used in solution, even when the greatest precautions were taken as to its proper instillation, and yet I use them but rarely, relying almost invariably upon the watery solution. The cause for this difference in the quantity of homatropine used is, of course, due to the wasting of the mydriatic when used in solution.

As for the combination of homatropine and cocaine of which Dr. Stewart speaks, there is one very important fact to be mentioned, that is, that every once in a while after the use of this combination we will find a hazy cornea that is due to a disturbance of the corneal epithelium occasioned by the cocaine, and sometimes this disturbance of the epithelium will occur in a case where it will interfere completely with the determination of the refraction. It is almost impossible to determine the exact amount of astigmatism when the cornea is thus disturbed, the greatest interference being in cases of astigmatism of small amounts, and here we occasionally will be compelled to discharge our patient for the day without having obtained any satisfactory results, being compelled to examine the patient at some other time under the influence of this or some other mydriatic.

Dr. Edward Jackson: Some careful comparative tests convinced me that the gelatine discs containing homatropine and cocaine produced a somewhat greater effect on the accommodation than did a drop of the solution containing the same amount of the drugs. A single disc did not, however, in any case produce complete and satisfactory paralysis of the accommodation in a young person. Two discs commonly did.

With such discs, as after any use of cocaine for measuring refractions, one must remember the precaution of keeping the eyes closed to avoid drying of the corneal epithelium and consequent irregular astigmatism. My trial of the gelatine discs has not led me to adopt them in the place of solutions.

Dr. Chas. Hermon Thomas: Homatropine in solution of 1 to 40, dropped into the eye at intervals of five to ten minutes four or five times, is an effective means of completely paralyzing the accommodation. But these instillations should be made by the surgeon himself, and the refractive measurement should begin within a short time after the last instillation.

There is a little knack which I have been in the habit of resorting to for some years, which, I think, is of practical value. It consists in striking off a small drop from the pipette upon the edge of the upper lid, slightly separated from the globe, but without eversion. This manipulation favors the distribution of the alkaloid over the cornea, Used in this way, I have never seen conjunctival or ciliary irritation of any importance, certainly nothing to interfere with a satisfactory measurement.

The atropia discs of Savery and Moore, to which allusion has been made, were tested at Wills Hospital when I was a resident in 1865. The immediate effect of the application of these discs was found to be more disturbing to the patients than the solution, and their use was, therefore, soon discontinued.

Dr. L. Webster Fox: The use of medicated gelatine discs in ophthalmic work dates back for more than a decade of years. I have a variety of these discs in my possession which I brought with me from London in 1881. I still occasionally use them, and find them to answer as well as certain aqueous solutions of the same drug.

I had samples of the gelatine discs, described by Dr. Stewart, sent me by Wyeth Bros., which were made after the formula suggested by Dr. Casey Wood, *i. e.*, homatropine and cocaine in combination. I found that the use of this combination produced two distinct trains of symptoms in the eyes of the majority of my patients: First, great irritation to the conjunctiva and corneal epithelium; and second, on account of this corneal disturbance, the transparency of the cornea was lessened, and in consequence the visual acuity was modified. I had discs made containing homatropine alone, hoping thereby to lessen the corneal disturbance, but I must say that I get equally good results from aqueous solutions, and with much less conjunctival irritation and annoyance to patients. They are not without advantage, however, and in certain forms of iritis I use them, combining the drug daturine instead of atropia.

Dr. Geo. E. de Schweinitz read a paper on "Some Cases of Obstructive Disease of the Lachrymal Passages and the Associated Intra-Nasal Lesions." (see page 688.)

Dr. Edward Jackson: I have very little to add to this paper. We are not in a position to generalize widely on this subject

or determine how many cases, or what proportion of cases, belong to this group in from which the obstruction comes originally the nasal chambers. Certainly I have not studied enough of these cases to go further than simply consider individual instances and study the lessons they seem to teach. A case that comes now to my mind is one that was treated some years ago at the Polyclinic for lachrymal obstruction. He recovered, or at least got in such a good condition that he ceased to attend. Within a few months he returned to the clinic with a renewal of his epiphora, and on passing a probe I found no obstruction until the lower end of the duct was reached. There the obstruction was very noticeable, although no difficulty was experienced in passing the probe. He was referred to the nose and throat department, and there was found a cicatrix involving the lower end of the duct. Whether this cicatrix was connected with the former treatment, or whether it resulted from the original nasal lesion, I am not prepared to say. Its removal certainly removed the obstruction to the flow of tears.

I recall two cases in which the thickening of the mucous membrane at the opening of the duct into the nose was the sole cause of the epiphora. Probably in the great majority of cases of lachrymal obstruction the original obstruction has been seated at one end of the canal. I do not think that it is always, and perhaps not in the majority of cases, that the trouble begins at the lower end of the canal coming from the nasal chambers. Frequently it commences with the puncta. Some of the obstinate cases that have come to me with a history of slitting up of the canaliculi, and long-continued treatment with probes without permanent benefit, have shown a grave error in the position of the incision into the canaliculus. Instead of on the conjunctival surface, the cut has been made on the upper edge of the lid, so that the tears could not get into the passage until they ran over the edge of the lid. These cases are liable to a return of the acute trouble, for if the normal flow of the fluid through the lachrymal sac and duct be not sustained micrococci which enter find the conditions most favorable for free development and the setting up of pathological processes.

Dr. Samuel D. Risley: The facts that Dr. de Schweinitz has set forth in this admirably reported group of cases are of great practical importance, both to the ophthalmologist and those who treat the diseases of the naso-pharynx. The conditions so aptly described suggest many points of great importance. It recalls some of my experiences in the treatment of lachrymal disease.

I remember the case of a Mr. C., whom I had treated for a long time in 1879 for lachrymal retention unsuccessfully. There was no stricture of the duct other than that due to a more or less uniform thickening of the mucous membrane, but there was, nevertheless, more or less constant epiphora. Incidentally, he called my attention to some trouble with the nostril on the side of the affected tear-duct. I discovered a broad superficial ulcer underlying the anterior end of the inferior turbinated bone. This was speedily cured by a few applications, and his lachrymal trouble soon disappeared. This was the first inkling I had received of the important relation which might exist between certain cases of lachrymal disease and affections of the nasal passages. At that time, so far as I knew, literature was silent upon the subject. From that time to this it has been my uniform practice to carefully inspect the nose in every case of lachrymal disease.

Dr. de Schweinitz's paper is an admirable statement of facts, with which my own experience is strictly in accord in a large group of cases suffering from this very troublesome and persistent affection. These facts explain why so many cases of epiphora present no marked stricture of the lachrymal duct. I have also had experiences the counterpart of that related by Dr. Jackson, where the probe was passed freely until the nasal end of the duct was reached, and there, meeting with resistance, if forced roughly into the nose will cause bleeding from laceration of the inflamed and swollen mucous membrane, closing or blocking the nasal orifice of the canal.

Another practical bearing of these facts in ophthalmic surgery is, that since the lachrymal passages are liable to disease by extension upward from the nose, which furnishes such perfect conditions for the rapid development of micro-organisms, the nasal passages may become the source of infection for the eye itself. It suggests the necessity for great care in this direction, particularly before and after operation upon the eye. We may deluge the conjunctival sac with antiseptic lotions before opening the anterior chamber, bandage the eye, and imagine that all has been done for the safety of our patient, whereas the facts set forth this evening suggest the possibility of infection from the nose through the lachrymal duct. With this possibility in mind, I have of late years recognized the importance of washing out the lachrymal sac and nasal passages with bichloride of mer-

cury solution where I expect to bandage the eyes after operation.

If affections of the nasal mucous membrane are then the origin of a considerable group of cases of lachrymal disease, it is obviously unwise to treat the duct harshly by probing until after the nasal disease is excluded. The function of the lachrymal duct is not performed in the manner of a drain-pipe, but is rather a capillary tube, and its inflammations may often be cured by washing with suitable lotions. Probing is often necessary, but rarely with the idea of dilating the capillary tube into an open canal. In 1877 I urged that the proper function of the probe was to induce absorption of the products of inflammation in the thickened membrane lining the duct, rather than the rupture of a stricture or dilatation of the duct.

Dr. Alexander B. Randall: I do not think I can add anything to what has been said. I have not met with a great deal of lachrymal trouble in the three or four thousand cases seen at the Episcopal Hospital. I have met, in that number, with only thirty that required absolute lachrymal treatment. I recall a large number of cases where the nasal trouble seemed to be the cause of the affection, and where treatment directed solely to the nose has resulted most happily. In a large number of cases of children with watery eyes I have never, I believe, with one exception, used any other treatment than that to the nares and lower end of the duct, and have had no reason to regret the absence of other forms of treatment. I have always thought that the puncta, and the arrangements of the upper part of the lachrymal passage, had a decided physiological purpose, and that it was a great disadvantage to treat these parts by incision and probing if there was no absolute necessity for it. In directing attention to the primary incision and to the constitutional treatment of the case, my results have been most satisfactory with a minimum amount of necessity for surgical procedures directed to the upper part of the lachrymal passages.

Dr. Ralph W. Seiss: With regard to the nasal lesions found in these cases, in the instances that I have seen they have been almost altogether of two types. One is enlargement of the anterior nasal spine with ecchondroses of the septum and swelling of the mucous membrane; the other is atrophic and sclerotic changes. It is important to keep this in mind, as it has an important bearing upon the treatment. The galvano-cautery is an admirable agent in the treatment of nasal troubles, but it must be used with caution in these cases. I have seen seven or eight cases of lachrymal obstruction following the reckless use of this agent to the lower turbinated body. When I receive such a case for treatment I am more apt to use trichlor-acetic acid or a single crystal of chromic acid than the cautery.

Dr. L. Webster Fox: There was one point which was not discussed by Dr. de Schweinitz in his paper, and yet my observations have led me to believe that it plays a very important rôle in the causation of lachrymal disturbances, and that is, asymmetry of the face. A deviation from the middle line by the nasal bones or septum would perforce cause a modification of the calibre of the lachrymal canal on that side. Any irritating substance lodged in this constricted channel could not find easy escape, and in consequence inflammation develops which eventually would lead on to lachrymal abscess. Then, again, closure of both upper and lower openings of the canaliculi caused by chronic conjunctivitis or blepharitis, proves again that asymmetry must play a factor in these cases, for with both eyes afflicted more or less, but one side of the drainage canal is affected. In 1884 all cases of lachrymal obstruction applying to the eye department of the Germantown Hospital were referred to Dr. S. MacSmith for nasal examination. I was in hopes that we could trace all lachrymal disorders to disturbances in the nasal cavities, but we are doomed to disappointment. While a certain number of cases had undoubted nasal complications, yet in many the lesion was found on the side opposite to the epiphora or lachrymal abscess. In some few cases we found the applied treatment to the nasal cavity did give relief, but in the majority we found that you must apply treatment to the orbital end of the canal to obtain good results. Dr. de Schweinitz did not dwell upon the treatment of lachrymal disturbance, which I regret; for, after all, we desire to learn from each other the best means by which a cure may be brought about, or at least to alleviate our patients.

My experience has led me to adopt the larger Cawper probes, followed by the insertion of a silver tube. In certain forms of epiphora a simple dilatation of the mouths of canaliculi will alleviate the patient, or slitting up, as suggested by Mr. Bowman; but where you have a stricture or lachrymal abscess, or both, I adopt the radical treatment—dilatation to its fullest capacity. As regards the application of astringent washes,

I have never had much success from their use alone.

Dr. Charles Hermon Thomas: The paper which Dr. de Schweinitz has read is an interesting and valuable contribution to the traatment of lachrymal obstruction. It, and especially the discussion which has taken place, has strongly emphasized a phase of the subject on which I confess I have not laid much stress in my own experience, which has withal been a not unsuccessful one. For a good many years I have had such satisfaction in the treatment of these cases as to leave little to be desired. I do not doubt that many of these cases can be relieved from the nasal side, but I must believe that there are a number of cases which can hardly be treated successfully in this way, exclusively cases in which the irritation has been so long continued that it has resulted in what might be called organic stricture as distinct as stricture of the urethra. Such cases certainly demand local treatment at the point of obstruction.

It was in 1868 that Stilling made the announcement of the results obtained by the use of the knife which he devised for the purpose of cutting strictures of the lachrymal duct. I was impressed with the value of the method of treatment proposed by him, and also with the want of adaptation of the knife which Stilling figured for the purpose. It seemed to me that the stiff, conical blade was faulty. I therefore devised a knife with a blunt conical tip, with the edge so set as to cut in withdrawing only, and attached to a flexible shank so that it could be bent to conform to the shape of the bony canal, and yet be rigid enough to control the blade. By slitting the lower canaliculus and first passing some of the more delicate probes, especially those of Dr. Williams, of Boston, this knife may be slipped down and a free linear incision made. The stricture is then divided completely even to the bone, and a large leaden style is introduced and allowed to remain for a few days or weeks at most, being removed daily for a time, for the purpose of washing the passage with some antiseptic fluid. By this method I have had such success as seems to leave little to be desired, and can hardly think that the time has arrived to abandon that method altogether and turn these cases over to the rhinologist. Indeed, I do not now recall a single case in which I had difficulty from obstruction at the lower end after I had gotten a passage through. The facts brought out by Dr. de Schweinitz doubtless make it most desirable to have the nasal passages of patients suffering from epiphora examined, and any abnormalities found therein treated. It is my purpose to return to this subject in the near future, and to enter more into details as to the method of treatment here briefly sketched.

Dr. George M. Gould: I wish to go one step further that Dr. Thomas in emphasizing the importance of ophthalmological treatment as such. There can be no question as regards cases such as Dr. de Schweinitz has presented. When there is absolute impermeability of the nasal end of the duct, the treatment is, of course, outlined by the diagnosis. In the greater number of cases, however, there is not absolute obstruction of the duct, but simply a stenosis, an unhealthy congested condition of the lachrymal mucous membrane, the duct certainly being patent to some extent, but not enough to carry off the large excess of tears. The frequent use of probes has seemed to me not only not necessary but simply superfluous in these cases.

During the past year I employed a plan of treatment in such cases, which has been so successful that I shall outline it. It consists in slitting the punctum vertically downward toward the palpebral fold, in order to increase the size of the opening. Then canting the patient's head to one side, the corner of the eye is filled with an antiseptic astringent lotion. The duct should first be emptied by pressure, and then allowed to fill with this solution. This procedure of emptying and refilling the duct is repeated several times, and thus the antiseptic solution is brought in contact with canaliculus, sac, and duct by capillarity and pressure. I have had cases in which, after showing the patient the method once, he has afterward practised it himself and came back in a week perfectly cured. The method is simple and effective, and can be carried out at at home. I have often wondered in those cases where probing has been employed, whether it was the probe or the antiseptic lotion that had done the good.

In regard to slitting of the canaliculus, I may say that I do not do this at the beginning of the treatment. If there is narrowing of the puncta the fluid enters more readily if it this cut.

Dr. George Friebis: I should like to ask whether, in the experience of Dr. de Schweinitz, he has met with obstruction due to such causes as inflammation and enlargement of the caruncle. I have in mind one case (a male adult, past middle age), in which I paid little attention to the inflamed caruncle, and the case did not improve under the routine treatment. Upon recognizing the

inflammation of the caruncle as a possible cause, and treating it with astringents, I succeeded in curing the epiphora without further instrumental interference.

Dr. de Schweinitz: I have presented this series of cases simply for the purpose of classifying one of the many varieties of lachrymal obstruction. I beg Dr. Thomas will not think that I wish to transfer the treatment of lachrymal obstruction to my friends, the rhinologists, much as I value their aid in the management of some of these cases, and I heartily agree with Dr. Thomas and with Dr. Gould, that the ophthalmological treatment of lachrymal obstruction is of paramount importance. These cases illustrate merely certain failures in treatment when applied to the ducts alone, because there is obstruction either at the inferior end of the duct or from intra-nasal lesion. I have not intended this evening to include the large number of cases due to obstruction in the canaliculus from polypi, from tear-stones, from fungus, or to the cases of obstruction high up, or to those which result from conjunctivitis and from malposition of the punctum lachrymale. Dr. Fox's observation in regard to asymmetry of the face is an important one, and deserving of much study. In regard to the use of large probes, I might not find myself in accord with Dr. Fox. Abnormal position of the caruncle or its enlargement, as referred to by Dr. Friebis, is an interesting anomaly. You are all familiar with the cases reported by Von Graefe and by Horner. I have some knowledge of a similar case occurring in the practice of Dr. Wallace, of this city. Cases of this character, or others which have been brought up into discussion, have been purposely omitted in the paper of this evening. My idea was simply to show that certain examples exist, and they are not infrequent, which can be treated better with than without the aid of the rhinologist.

FLORES ROSARUM IN CHRONIC DIARRHEA.

Alexjewski recommends the flowers of the red rose as a remedy for the treatment of chronic diarrhea. It is a favorite house remedy for this trouble among the Russian people. A handful of the dried flowers is made into an infusion. Children up to 5 years take a tumbler of the infusion in the course of a day. Adults may take from two to three tumblerfuls. Its taste is agreeable, especially if some sugar be added. It has cured some obstinate cases of diarrhœa in less than a week.—*St. Petersburg Med., Wochenschrift.*

SELECTED FORMULÆ.

TONIC.

℞
Tinct. nucis vomicæ.....gtt. j
Acid. hydrochloric. dilut.....gtt. ij.
Extract. cascaræ fluid .....gtt ij.
Tinct. gentianæ comp.....gtt. v.
Aquæ .....ad f ℥ j.
M. To be given three times a day.

MILK SUBSTITUTE FOR INFANTS.

Dr. L. Rochester, M. D., has used with success the following, in cases when the mother's milk was insufficient in quantity, or when it was desired to wean the infant:

℞
Yolk of egg.....No 1.
Sugar of milk.....teaspoonfuls 6.
Filtered water.....oz. 7.
Dissolve the sugar of milk in the water and add gradually to the yolk of egg, stirring constantly.

This is fed perfectly cold, in small quantities at a time, for twelve hours, gradually increasing the amount and lengthening the intervals, until finally the full amount is given four times in the twenty-four hours.

RESORCIN IN SEA SICKNESS.

The following (*Lo Sperimentale*, No. 18 1891) is praised in sea sickness:

℞
Resorcin resubl.....dgms. 2–1.5.
Sacchar. lactis..... " 5.
Mix and divide into thirty powders. One powder every two hours.

HORSE BLISTER.

An extra strong one, which gives great satisfaction:

℞
Yellow wax.....ounces 3.
Lard..... " 4.
Corrosive sublimate.....drams 4.
Powd. cantharides.....ounces 2.
Oil of turpentine.....drams 4.
Barbadoes tar..... " 4.
Melt the wax and lard and stir in the other ingredients, first reducing the corrosive sublimate to impalpable powder.

—*Pharm. Rec.*

GOUT.

In *Hygeia* occurs the following:

℞
Collodion.....℥ i.
Ether sulph.....℥ i.
Acid salicyl.....ʒ i.
Morph. sulph.....gr. x.
S. Apply locally with a camel's hair-brush every hour

ANTI-NEURALGIC OINTMENT.

℞
Veratrin..... 0.03.
Morph. muriat..... 0.02.
Adipis..... 30.00.
M. Sig. The veratrine should first be dissolved in a little alcohol. Apply with friction.

FUNCTIONAL IMPOTENCE.

℞
Ext. cannabis Indic.....gr. v.
Ext nucis vomicæ..... " v.
Ext. damianæ..... " xx.
M. et ft. pil. no. xx. Sig. One pill after meals and at bedtime.

—*Med. Age.*

PALATABLE PREPARATION OF COD LIVER OIL.

Prof. Parvin recommended to the class the following formula, which he had found that children would take very readily:

℞ Olei morrhuæ..... f ʒ viij.
Olei gaultheriæ..... f ʒ j.
Calcii phosphatis..... gr. cclvj.
Pulv. accaciæ,
Sacchari albi..... āā ʒ ij.
Aquæ, q. s..... ad Oj.
M.

CHLORALAMID.

Galiana gives the following:

℞ Chloralamid..... gr. xxx.
Dilute hydrochloric acid..... gtt. v.
Distilled water..... ʒ ii.
Syrup..... ʒ ii.
S. For two doses.

℞ Chloralamid..... gr. xv.
Infusion of tea.
Sugar āā enough to make a sweet solution.
S. At a dose.

—*Médicine Moderne.*

LEUCORRHŒA.

Prof. C. Braun, of Vienna, recommends in leucorrhœa, associated with chlorosis, the following:

℞ Ferri sulph. cryst.,
Potassii carbonic. et tartara..... āā ʒ j ¼.
Extr. et pulv. r. gentianæ q. s. ut
fiant pil. No. 60.
Sig. Two pills, morning, noon and evening.

If the leucorrhœa be bloody, then:

℞ Ferri sulph. cryst.,
Potassii hydrocarbon..... āā ʒ j.
Ergotin pur..... gr. xxiij.
Extr. et pulv. r. liqueritiæ, āā q. s,
ut f. pil. No. 50.
Sig. Two or three pills, morning, noon and evening.

If constipation be present, then:

℞ Ferri sulph. cryst.,
Potassii hydrocarbon..... āā ʒ j.
Aloes lucid..... gr. xxx.
Sig. A teaspoonful, morning, noon and evening.

Or:

℞ Ferri oxydat. dialyzat..... ʒj ¼.
Aq. f. d..... f ʒ iv.
Syrup. rub. idæi..... f ʒ vj.
Sig. A teaspoonful, morning, noon and evening.

These last two formulæ are well borne by the stomach.

For the relief of pain the following prescription is invaluable. It was originally intended for the spasmodic colic of adults, but I have known it to be of benefit in so many other affections (angina pectoris, asthmatic paroxysms, etc.,) that under no circumstances would I like to be deprived of the formula. Of course, it is most useful in troubles into which a convulsive element enters:

℞ Spts. chloroformi..... ʒ iij.
Tr. opii camph..... ʒ vj.
Tr. cardamomi comp. q. s..... ʒ iij.
M. Sig. ʒ ss pro re nata.

—*Ex.*

ACUTE BRONCHITIS.

The following (*The Prescription*, No. 1, 1892) is praised:

℞ Vin. ipecacuanhæ..... fl. ʒ ij.
Liq potass. citrat..... ʒ iv.
Tinct. opii camphorat.,
Syrup acaciæ..... āā fl. ʒ j.
One teaspoonful three times a day in an ordinary case of bronchitis.

ENDOMETRITIS.

Dr. Terrier (Paris) prescribes the following:

℞ Pulv. iodoform..... ʒ jiss.
Gum tragacanth..... gr viii.
Gl cerin., aquæ distillat., ana q. s.
This suffices to make ten pastilles.
Sig. Insert into the uterus and hold in place by a tampon.

—*Journ. de Med. de Paris*, No. 30, 1890.

FORMULA FOR THE ADMINISTRATION OF QUININE TO CHILDREN.

Dr. Lutz (*Gazzetta degli Ospitali*, No. 86, 1891) proposes the following:

℞ Sulphate of quinine..... cgms. 50.
Dilute sulphuric acid (1 per cent.)... " 50.
Essence of peppermint..... gtts. 5.
Saturated solution of saccharine..... gms. 10.
Water..... " 90.

CARDIAC DILATATION.

For cardiac dilatation, with slight congestion of the lungs, due to rheumatism, in a man aged thirty-seven years, Prof. Da Costa gave the following treatment:

℞ Tinct. digitalis..... gtt. x.
Tinct capsici..... gtt. j.
Tinct. cardamom..... f ʒ j.
M. Sig. Three times a day.

And two or three times a week give calomel, gr. j, in the evening, followed by a saline cathartic in the morning. The diet is to be chiefly of meat, with the use of a moderate amount of alcoholic liquors.—*Ex.*

INCONTINENCE OF URINE.

For incontinence of urine in children, due to exposure to cold, Prof. Hare recommends the following treatment:

Where the urine is high-colored and concentrated, and the child has fever, give—

℞ Tinct. aconit..... gtt. xij to xxiv.
Spirit ætheris nitrosi..... f ʒ ij to iv.
Liq. potass. citratis,..... ad f ʒ vj.
M. Sig. ʒ ii every three hours.

After the urine has become more dilute, belladonna can be given with advantage, to allay the irritation and spasms of the bladder.

Or when the incontinence is due to paralysis of the bladder, give—

℞ Extract. nucis vomicæ..... gr. ij.
Acid arseniosi..... gr. ⅓.
M. Fiant pil. xx. Sig. One pill three times a day.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

THE BUTLER PUBLISHING CO. (Incorporated)

PROPRIETOR AND PUBLISHER.

DIRECT ALL COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor,
(Professor of Physiology, University of Penna.)

CHARLES K. MOUNT, Advertising Manager.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable to the BUTLER PUBLISHING CO., and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates),..... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts,.....$1.50 each.
Bovine Points or Quills,..... 1.00 a doz.
Humanized Crusts,..... 1.00 small.
Humanized Crusts,..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

LEADING ARTICLE.

HYDRASTINE IN UTERINE HÆMORRHAGES.

Whenever a new remedy is introduced into therapeutics, says a recent German writer, the profession of to-day is prone to regard it with the utmost skepticism. This may be true perhaps of the naturally pessimistic, or rather, cautious German physician, but it surely cannot be said of the average practitioner in this country.

To be sure, within the last ten years, medical journals and books have been flooded with a list of remedies of vaunted specific efficacy, the majority of which have faded from sight under the critical light of clinical experience and scientific investigation, and it would be well, perhaps, and just, did a more pessimistic tendency prevail in the profession on this side of the Atlantic. Nevertheless, many valuable remedies have been rejected and allowed to fall into disuse when only half tried, and a few initial failures, due, perhaps, to faulty method of administration rather than an inefficacy of the drug, have led to a wholesale condemnation of what might prove most valuable if properly used.

This seems to have been the fate of hydrastine, a drug which was first recommended in uterine hæmorrhages some two years ago by Falk. Although Falk at that time reported an improvement or cure in 84.6 per cent. of the cases in which he had tried the remedy, no one has since endeavored to follow up this line of research to prove or disprove the value of the drug, and yet without doubt many practitioners have seen cases of uterine hæmorrhage where the usual remedies, such as ergot, hydrastis, and others, have left him entirely in the lurch.

Before conducting experiments upon the human organism, Falk made a most careful series of experiments upon animals in order to determine both the exact action of the drug and the possible effect its exhibition would exert upon the general health of the organism. He found it entirely without ill effects. The results of these experiments

were as follows: Hydrastine is not a cardiac poison, it acts as a vascular contractor in animals, probably through an excitation of the vaso-motor centres, but chiefly by a direct action upon the blood-vessels themselves. In consequence of this action there is an increased blood-pressure. This at first occurs periodically, and is very marked, lasting and uncoupled by any period of relaxation. The action of hydrastine is entirely confined to the circulation, and unaccompanied by any unpleasant action. It was particularly observed that no symptoms of irritation of the spinal cord were manifest, and that the heart's action was influenced favorably.

These results obtained by experiment upon animals seemed to justify Falk in testing it clinically, and he did so, with remarkable success.

The subject, dropped for so long, has been taken up by Dr. Karl Abel, of Berlin, who publishes the results of his clinical experiences with hydrastine in uterine hæmorrhages in the *Berliner klinische Wochenschrift*, for Jan. 18, 1892. He has used the drug in a very large number of cases, and with remarkable success.

It may be hardly necessary to state that hydrastine was not used in such cases of internal hæmorrhages as result from a retention of placental remains, the presence of polypi, carcinoma, or other foreign growths. In such cases only a radical removal of the cause can efficiently check the hæmorrhage. Again, in such cases where heart failure was looked upon as the cause of the hæmorrhage, hydrastine was not given. In these cases also, the original cause was primarily treated.

The remedy was tested in cases where an objective anatomical condition existed, and also in cases in which such a condition was absent.

To this first-named category belong primary hæmorrhages in cases of endometritis, metritis, and myoma, as well as secondary hæmorrhages in diseases of the ovaries and tubes, such as parametritis, cysts of the tubes, and tubo-ovarian tumors. To the second category belong the menorrhagias and metrorrhagias, in which cases no objective condition can be ascribed as a cause of the hæmorrhage, which can usually be designated as ovarian or congestive hæmorrhages. It is especially in these last named cases in which the use of hydrastine is followed by the best results.

Hydrastine should always be given hypodermatically, as the results obtained when given per os are far from satisfactory. The injections should be made on the right or left side of the lower portion of the abdomen. A ten per cent. aqueous solution of the nitrate of hydrastine should be used, and of this from one-half to one gramme injected at at a dose. The patients will frequently complain of a burning pain at the seat of the injection, but this usually lasts but a short time, yet if severe can be relieved by cold applications. The day after the injection, in the majority of cases, the seat of the puncture will be found to have assumed a dark blue color, about the size of a half dollar, and in one case Abel noted that this discoloration extended over the entire abdomen. The discoloration, however, gradually disappears, but the seat of the puncture is painful upon pressure for quite a long time. No abscess was ever observed.

The number of injections necessary depends, naturally, upon the nature and severity of the case. If the case be one of ovarian hæmorrhage which merely takes the form of an intensified and prolonged menstruation recurring every four weeks, Abel usually gave one injection of half a gramme of the above named solution during the week before the appearance of menstruation, and during the period daily injections of one gramme. If this treatment gave rise to an improvement, then the injections would only be repeated once a week until the next period.

Almost without exception after two or three months of the above treatment the periods would become normal and remain so. If occasionally there was a slight relapse, a single injection given during the course of the period was sufficient to cause an almost immediate cessation of the hæmorrhage.

If these congestive hæmorrhages do not assume the regular type of the menstrual

periods, but occur at irregular times, varying from two to three weeks, the treatment must be a more energetic one.

Under the circumstances Abel injected one gramme of the hydrastine solution two to four times a week, and during menstruation one gramme daily. Usually these measures resulted in a marked improvement when the first period occurred, since they usually delayed this for four or five days. If the treatment was continued the second period usually did not occur until after a normal lapse of time, or four weeks, would last but five days, and would be accompanied by but slight loss of blood. Simultaneously the severe dysmenorrhœic pains would disappear.

In cases of endometritis we are either dealing with a condition of glandular hyperplasia or fungus endometritis. Hydrastine was used successfully in both of these conditions. The drug was given in doses of one gramme; two injections a week being administered between the menstrual periods, and one injection a day during the period. In several of the cases in which the drug was tried, the curette had previously been used. A continued treatment, however, resulted in bringing about a normal condition, in so far as menstruation was concerned. In the cases of glandular hyperplasia, the periods between the flow will be rendered of normal duration, yet the flow may frequently remain copious for a long period, and in such cases one or two injections during the course of menstruation will render the amount also normal.

In one case of metritis with profuse menorrhagia, Abel gave one injection a week, and after the sixth injection the patient was completely and permanently cured. Menstruation which had in this case lasted two weeks at once became normal, lasting only four or five days. In addition to this the womb gradually became reduced to its normal size.

In uterine myoma the drug does not seem to exert any more potent influence than ergotine.

We now finally arrive at a consideration of the secondary uterine hæmorrhages, caused by disease of the uterine adnexa, and principally by pyosalpinx and chronic parametritis. In the last named disease a decided improvement was seen to follow the use of hydrastine, while in pyosalpinx the action of the drug seemed of rather an uncertain character. In one case of double pyosalpinx, when the patient was never free from hæmorrhages for longer than a week, daily injections of hydrastine at first caused a rapid improvement, the patient being free from hæmorrhages for two weeks at a time; but later the drug seemed to lose its effect, and the ovaries were finally removed. In another case of left-sided pyosalpinx, the action of hydrastine was remarkably successful, a complete and lasting cure being obtained.

Finally, the drug has been given in cases of hæmorrhage occurring during gestation with good results, and the several writers on the subject agree that its use will in no way tend to cause an abortion.

In conclusion, if we sum up the experiences of Falk, Abel, and others, it appears that in the subcutaneous administration of hydrastine we have a remedy of undoubted efficacy, and of greater certainty in action than any other in cases of uterine hæmorrhages; and, moreover, that in many cases its judicious use may result in a complete cure of the morbid process. By its use we may undoubtedly be frequently spared the not always easy operation of curetting, and in doing so surely avoid a possible danger to the patient. The treatment is a conservative one, and can not infrequently remove the necessity of a laparotomy for the removal of the ovaries and tubes. As such it commands our careful consideration.

DISINFECTANT INJECTION IN CANCER OF THE UTERUS.

Dr. Cheron makes use of this formula in cases of uterine cancer:

℞

Natr. salicyl	ʒ jss.
Acid salicyl	ℳ xv.
Tinct. eucalypt	f ʒ jiss.
Acet. vin	f ʒ xvj

Sig. Inject per vaginam one to two teaspoonfuls to a pint of warm water.

—*Deutsche medicinische Wochenschrift*, 5, 1890.

PERISCOPE.

THERAPEUTICS.

JAPANESE MASSAGE.

With the exception of some musicians, and a few who may be supported privately by relatives or who are in asylums, the blind of both sexes in this country are engaged in one calling, and have a complete monopoly of that profession. This calling, in the vernacular, is denominated *amma*, and is usually translated "shampooing;" while the operator himself goes by the name *amma san* ("Mr. Shampooer"). This operation, as will be seen later, is in reality a kind of massage treatment, much employed by the natives when they are tired or a little indisposed. It is especially "recommended to tired pedestrians, and to persons suffering from lumbago, rheumatism and other pains and aches." It is, among the lower classes, a very common remedy for colds and headaches.—*Dietetic Gaz.*

PREVENTION OF COCAINE POISONING.

Accidents from the use of cocaine have become so numerous that it is looked upon by some as too risky a drug to be administered. This is a pity, since with caution it may certainly be used without fear.

Patients should be prepared by giving them a drop of a 1 per cent. alcoholic solution of trinitrine a minute before administering the cocaine, repeating the dose at intervals if the pulse be not affected and no pain or fulness in the temporal region be felt. The trinitrine acts almost as rapidly and continues to affect the vaso-dilators for upwards of half an hour longer than nitrite of amyl, which Professor Lepine has proposed, but which, on account of its fleeting action, has failed to gratify the hopes to which it gave rise.

Professor Lepine has pointed out the importance of paying attention to the type of patient. The nervous are to be encouraged and calmed, the anæmic made to lie down before administering the drug, for thus, as Dujardin-Beaumetz points out, cerebral anæmia is avoided. Dr. Lepine's statistics show that in the neighborhood of the face it is unsafe to inject hypodermically more than 2 centigrammes (one-third of a grain) at a time, and not more than from 4 to 5 centigrammes should be allowed to come in contact with a mucous surface. By taking these precautions accident is guarded against.—Dr. G. Cockburn Smith, in the *Brit. Med. Jour.*

STRONTIUM SALTS IN MEDICINE.

A discussion that has arisen in France out of the use of strontium compounds in the plastering of wines has turned attention to the physiological action of strontium salts. As a result, several communications on the subject have been presented almost simultaneously to the Société de Thérapeutique (*Rev, Thérap.*, November 15th, p. 604). In one, M. Ferré states that he has obtained with *strontium bromide* the same advantages as with the alkaline bromides in the treatment of epileptics, whilst it was better tolerated by the stomach. In a second, M. Sée stated that two to five gm. of bromide, dissolved in water, and taken in three doses in the course of the day, had been very useful in relieving dyspepsia, gastralgic pains, cardiac complaints, and Bright's disease. *Iodide of strontium* had also, in his hands, proved useful in heart disease. In a third, M. Paul reported that he had found the administration of a solution of strontium in lactic acid to cause the rapid and complete disappearance of albumen from the urine. In a subsequent communication, M. Dujardin-Beaumetz confirmed M. Paul's statements to the extent that in his experience the administration of the *lactate* had always promptly reduced the albumen by one-half. This result he appeared disposed to attribute primarily to the favorable effect of the salt on the digestive organs, which reduced the production of toxines to the minimum. M. Paul uses a solution of 50 gm. of "lactostrontiane" in 250 gm of water, the dose being a teaspoonful night and morning. —*Pharm. Journ.*

CURE OF RECURRENT ERYSIPELAS.

Dr. Lavrand relates the case of a woman who had repeated attacks of an erysipelas-like erythema, beginning at the sides of the nose, sometimes as often as twice in the month, but usually not proving severe. She suffered from chronic pharyngeal catarrh as well as hypertrophy of the middle and lower turbinated bones. Repeated medicinal as well as galvano-caustic treatment of the nose, which was looked upon as the port of entry of the infection, was without result, and the attacks continued. Cure was effected, however, by treatment of the naso-pharynx, and epecially by the removal of adenoid vegetations found there, and it was thought that the tissues made vulnerable in this location offered the real entrance for the erysipelas cocci.—*Deutsche Med. Zeitung*, No. 5, 1892.

A HAPPY APPLICATION OF INSUFFLATION.

Renault (*Le Progrès Médical*, 1891, No. 61, p. 475) records an instructive case occurring under his notice at the Maternité. A child about a month old had had a cough for three days, and at the end of that time was brought to the notice of the author. Well-marked broncho-pneumonia was found, with a temperature of 101⅘° F. Dyspnœa continued to increase until the following day, when the nurse in the ward was called to find the child in a state of almost complete asphyxia. The skin was cold, the face cyanosed, the lips blue, and the respiratory movements very shallow and failing. Without hope of reviving it, but rather that the mother, who was present, should not think the child was permitted to die without an effort at relief, the nurse took up the insufflateur, which was in daily use in the wards for resuscitating asphyxiated newborn infants, and applied it to the mouth of the dying child. After an occasional interruption in the operation during a period of five minutes, the bluish color of the face and lips began to gave way to a rosy tint. This unhoped-for success gave renewed encouragement to her efforts, and after a quarter-hour's work the child had so far been resuscitated as to permit of more active treatment with mustard bath, dry cups, and diffusible stimulants. Another attack of asphyxia was treated successfully in the same way, after which the case went on to an uninterrupted recovery.

THE USES OF STRONTIUM BROMIDE.

By experimental doses of salts of strontium in cases of chronic renal and cardiac diseases some good was found to be done, and this led M. Sée to make a careful study of the use of strontium bromide iu thirty-two cases of dyspepsia. He gave from 30 to 45 grs. a day, in three doses along with the meals; and those cases in which there was excess of hydrochloric acid rapidly improved and developed much less gaseous products. In six other cases, where there was vomiting with deficiency of acid, there was complete cessation of the sickness. Strontium lactate did not produce any good effect. Strontium bromide, as well as calcium bromide, was found of use by M. Sée in epilepsy, and this was confirmed by M. Féré, who found in fact that, owing to its easy agreement with the stomach, it was sometimes advisable to give strontium bromide in preference to the potassium salt.—(*Le Proyrès Méd.*, vol. ii., p. 311, 1891.)

ANTISEPTIC AND SEDATIVE TREATMENT OF HÆMORRHOIDS.

This treatment has been successfully used by Dr. Kassobudski for external and also internal hæmorrhoids. (1) For internal hæmorrhoids: chrysarobin 1 gm., iodoform 30 cg., extr. belladonna 50 cg., cacao butter 20 cg.; to be made into six suppositories. One suppository to be used a day. (2) For external hæmorrhoids: a lotion of corrosive sublimate (1 : 1,000) or phenol (1 : 50) is used several times a day, succeeding which chrysarobin salve is applied, made of the same ingredients as the above suppositories, except that cacao butter is replaced by vaselin 30 gm.—*Revue de Thèrapeut.*, 1891, p. 49.

CARDIAC TONICS.

In a very instructive lecture on the cardiac tonics, G. Sée (*Médicine Moderne*, July 2, 1891) arrives at the following conclusions:

Digitalin increases the diastolic elasticity of the heart, thus increasing its capacity and allowing more complete filling of the arteries. The systole is not exaggerated, and the vessels are not always contracted, so that digitalin regulates the action of the heart without strengthening the organ. It is best given, if a large dose, (half a milligramme, one-seventy-fifth of a grain) be indicated, twice on the first day, followed in the following two oa three days by small doses to sustain the effect. Even then one is obliged to wait before the desired result is obtained, as the drug is but slightly soluble, and owing to the feeble condition of the patient absorption may be slow.

Iodide of potash acts similarly; it dilates the vessels still more, and considerably facilitates the peripheral circulation as well as that in the nutrient vessels of the heart. From the latter point of view it is a cardiac nutrient; from the former, it regulates its action, especially if there be pulmonary congestion, dyspnœa or asthma. One gramme (fifteen grains), should be given in milk or beer three times a day with meals for five days out of seven, and indefinitely continued.

Strophanthin is an energetic vaso-constrictor; it increases the force of the heart only indirectly, and its effect is transitory. It acts promptly and does not accumulate, one-fourth of a milligramme should be prescribed, either in tincture or pill form.

Spartein and convallamarin are often indispensable auxiliaries of the preceding drugs. The action of the first is almost instantaneous, but its effect is soon lost, so that it should

be given two or three times daily; two to four grains may be given in twenty-four hours. Convallamarin has no cumulative action, and five to eight grains may be given daily.

Caffein is especially valuable as a diuretic in dropsy of cardiac organ; it is also a general excitant, but not especially of the heart.

Lactose, like caffein, is a renal diuretic and has no action on the heart or vessels.

ON THE EMPLOYMENT OF DRYING LINIMENT IN THE TREATMENT OF SKIN DISEASES.

The use of medicated gelatines, as recommended many years ago by Pick, is admittedly attended with some discomforts, and is not altogether satisfactory. The gelatine has to be warmed up every time it is employed, to be immediately and very uniformly applied to the part—a procedure of some difficulty and sometimes involving not a little pain—and the rapidity with which it dries reduces the possibility of absorption of any drug incorporated in it to a minimum, as the film is not in very intimate contact with the skin. Pick now recommends gum tragacanth as a basis, substance which, in contrast to gum arabic, does not dissolve in water, but melts down into a sort of a syrupy mass, which may be very easily smeared over the skin, and which on drying leaves a thin, delicate and colorless film. He considers the following proportions the most generally useful:—

Gum tragacanth	5 parts
Glycerine	2 "
Distilled water	100 "

and denominates the basis thus abtained a *linimentum exsiccans*. It may be prepared with cold or hot water, but preferably with the latter, as a thoroughly antiseptic preparation is thus obtained, which is not only easily applied, but as easily washed off with a little tepid water. Its application gives rise to a sensation of coolness which is specially noticeable and gratifying when it is used to congested or inflamed skin. Its advantages over fats is that it is not greasy, does not spoil the clothes, does not disfigure, and no further dressing over it is necessary. Remedies which are soluble in water can be incorporated in the liniment by being first dissolved in water used for its preparation. Substances insoluble in water can be rubbed into the basis in a fine state of division with very satisfactory results. Oily substances only alter its consistence and retard its drying to a perceptible degree when in very large proportions. Ichthyol, styrax, Peru balsam, oleum fagi, cadini, rusci, etc., may thus be used from 5 to 10 per cent. Insoluble substances, such as chrysarobin, zinc oxide, white precipitate, red and yellow oxide of mercury, iodoform, iodol, salicylic acid, etc., give the consistence of paste to the preparation if in large proportions, but without altering its characters, except perhaps by increasing the rapidity with which it dries up, and thus enhancing its value. The preparations thus obtained are very stable, and produce no constitutional symptoms, even when their local action is energetic. An advantage of these drying liniments claimed by Pick is that they are easily applied, and may be used in out-patient practice.—(*Vierteljahr, J. Derm.*, June, 1891.

THE VALUE OF BICHLORIDE OF MERCURY IN THE TREATMENT OF URETHRITIS.

Brewer (*Internat. Jour. of Surg.*) reiterates his confidence in the efficacy of bichloride of mercury in the treatment of urethritis. His method was as follows: At the first visit the patient was instructed in the proper use of a syringe, and was given a large amount of a solution of bichloride of mercury, varying in strength from 1 : 16,000 to 1 : 50,000, according to the sensitiveness of his urethra and the stage of the disease. This he was instructed to use twice daily, by taking ten injections in the morning and ten at night, holding each one in the urethra one minute to imitate as nearly as possible the result of irrigation. The patient was seen three times a week. As soon as the discharge lost its purulent character, bichloride was suspended and a mild astringent was substituted, preferably bismuth suspended in water. In the fifty-five cases treated in this way, five were not benefited after an average employment of the method for seven days. In the remaining fifty cases, the average length of time necessary to effect a change in the discharge from pus to thin watery secretion was a fraction over eight days. The discharge entirely disappeared on an average of twenty-one days. Epididymitis occurred in three of these cases, and posterior urethritis was developed in two. The reporter very fairly states that these statistics are of little value from a scientific point of view, since the cessation of the discharge can by no means be considered as an index that the disease has been cured. He offers his conclusions not so much on the basis of these cases as upon a very large personal experience, and states positively that the judicious use of bicloride of mercury in cases

of acute gonorrhœal urethritis is attended with better results in subduing the painful and disagreeable features of the disease than any other agent. The recovery is more rapid and permanent, and the frequency of inflammatory complications is very greatly reduced. —*Therap. Gaz.*

POTASSIUM PERMANGANATE AS AN ANTIDOTE TO PHOSPHORUS.

At a meeting of the Royal Society of Physicians of Buda-Pest, Bokai (*Deutsche medicin. Wochenschrift*, No. 47, p. 1294), as a result of chemical investigation and experiments upon animals, commended from one-fifth to one-third of one per cent. solutions of potassium permanganate as an antidote in cases of poisoning by phosphorus. Phosphorus in the presence of potassium permanganate is converted into innocuous orthophosphoric acid in the stomach, with the development of manganese chloride. Poisoned dogs thus treated were saved; untreated dogs died. Even one per cent. solutions of potassium permanganate exerted no injurious effect upon the coats of the stomach.

SALINE INFUSION FOR SEVERE HÆMORRHAGE.

Dr. R. H. M. Dawbarn, of New York, has devised a novel method of saline infusion, which he has employed with marked success in a case of severe uterine hæmorrhage, and which commends itself on account of its simplicity: The fluid injected is a solution of table salt in water that has been boiled, in the proportion of a heaped teaspoonful of the salt to a quart of warm water. All the appliances needed are a rubber bulb syringe, an ordinary soft rubber catheter or a small rubber drainage tube, and an ordinary hypodermic needle (a large size preferred). To avoid a cutting operation, with the searching for a small collapsed vein, the tying of the cannula, etc., Dr. Dawbarn makes the injection into the femoral artery, which can almost to a certainty be felt beating just above Poupart's ligament, even if the patient be pulseless at the wrist. The technique of the proceeding is as follows: Take the needle—not as yet attached to the catheter—and push it directly into this artery, going slowly, until bright-red blood is seen to well up from within the needle. As soon as the arterial blood is seen in the needle, slip over its base the catheter—already attached to the syringe, the nozzle of which has entered it at the eye, and both being filled with the salt-water, as hot as the hand can tolerate—and tie the thread tightly about the catheter, securing it to the base of the needle. Now, holding the needle in place firmly and steadily, pump the fluid directly into the arterial current. To avoid possible pumping of air by an old or leaky syringe, make an abundance of salt-water, and keep the entire syringe, with the hand working it, beneath the surface. In the case reported a full pint of the hot salt-water was thrown into the artery, taking nearly half an hour. After an interval of half an hour a second full pint was injected into the connective tissue of the thigh, as the circulation was then sufficiently strong to absorb the fluid into itself. Other restorative measures (hot applications, hot beef tea enema, small hypodermics of strychnine, etc.), were also employed.—*Internat. Jour. Surg.*

ANTIGALACTAGOGUE ACTION OF ANTIPYRIN.

Guibert has found that the lacteal secretion can be completely suppressed in from two to six days by antipyrin in daily doses of thirty grains or more, given in divided portions every two hours. After thus employing antipyrin in nineteen cases, it is regarded as harmless and of real service where it is desired to suppress the milk secretion.—*Le Practicien.*

EFFECTS OF SULFONAL.

In the *Journal of Mental Science* Dr. Carlyle Johnstone records his observations on the effects of sulfonal on fifty patients suffering from various kinds of mental disorders, including general paralysis, melancholia, and mania. His experiences with this drug point to the conclusions that in properly regulated doses it is an efficient hypnotic, and compared with that of other hypnotics, its action is fairly certain and constant. The sleep produced by it is natural and undisturbed by dreams; it has no injurious effect upon the appetite, circulation, respiration, or temperature, and the general health does not suffer under its use. After a time, the dose may be reduced or it may be discontinued, and the patient still continue to sleep well. Dr. Johnstone also found that it has a distinct sedative action in mental excitement and distress, and could be employed with great benefit in cases of insanity, especially such as are of recent or acute character. Its complete tastelessness also is recommended in such cases, allowing its combination of food or in milk in such a way as to escape

the notice of the patient. The chief drawbacks were found to be its slowness of action, and often the persistence of its saporific effect during the succeeding day, together with, at times, confusion, giddiness, and fatigue. After repeated doses, a dreary confusion was noticeable, and subsequently a slight weariness and fatigue, followed in a few days by enfeebleness and shakiness of motion, but nothing occurred which could be called an alarming symptom. As a rule, indeed, the mental condition improved, the excitement, irritability, and motor restlessness being diminished and the wretchedness dispelled. It will thus be seen that the writer's conclusions are in accord with the majority of those already published, and that while regarding sulfonal as by no means a perfect hypnotic, he is inclined to give it a very important place in the treatment of sleeplessness and restlessness generally. The best doses, he found to be between thirty and forty grains, and it should be given just before the patient lies down. The freedom of the drug from taste or smell, as has been said, is one of its advantages and renders its administration easy.—*Lancet.*

PHENACETINE AS AN ANTIPYRETIC.

The unexampled success of phenacetine, as a certain and safe antipyretic, has given rise to many clinical comparisons of that medicament with other febrifuges, but the results have served to increase the reputation of phenacetine. Professor Eickhorst, of Zurich, recently said (*Schweizer Aertse*, No. 5, 1892), "I have no great partiality for new antipyretics, for in my opinion fever should only be combated in emergency cases, and for this purpose some of the known antipyretics are amply sufficient. But if I should happen to find an antifebrile treatment necessary, I should certainly make use of phenacetine."

IODOFORM SPONGES.

Rettenheimer states that iodoform sponges may be prepared in the following manner: Suitable soft sponges are thoroughly boiled in water, then allowed to remain for five days in a five per cent solution of hydrochloric acid, and at the end of that time thoroughly washed in pure water to remove all acid, and finally dried. They are then placed in a 7.5 per cent. ethereal solution of iodoform and allowed to remain there until the ether evaporates.—*Pharmaceutical Record*, December 17, 1891.

MEDICINE.

INFLUENZA AND NEUROSES.

The following, according to Dr. George H. Savage, are some of the unpleasant things that influenza can do: Influenza, like other fevers, may set up psychopathy. Insanity may come on at varions periods of the disease. It may start any form of insanity. No specific symptoms result from influenza. The rôle of the influenza varies in the production of the insanity. It may be the predisposing or the exciting cause. In all cases there is some acquired or inherited predisposition. The insanity follows from altered brain-nutrition, possibly toxic. Onset of insanity often sudden and bearing no relationship to the severity of the influenza. The curability depends on the general rather than special conditions. The insane are less disposed to take it than the sane. Rarely it has cured psychoses. The insane may have mental remission during the influenza. There is no special indication in the treatment. Influenza may lead to crimes and medico-legal issues.—*Med. Press.*

PERI-URETHRAL ABSCESS IN CASES OF GONORRHŒA.

H. Christiani, of Geneva, reports a case (*Rev. Méd. de la Suisse Rom.*, October, 1891) in support of the view held by Pellizzari and others that Neisser's gonococcus, the micro-organism of gonorrhœa, is endowed with pyogenic properties. In peri-urethral abscesses, which are not infrequently met with after gonorrhœa, the ordinary bacteria of suppuration are often observed with or without gonococci. According to many observers, gonococci are never found alone in the pus of a peri-urethral abscess, but are always associated with other micro-organisms, especially the staphylococcus pyogenes, and consequently, this form of abscess is due to the presence of ordinary pyogenic microbes, and not to that of the gonococcus, which is simply accidental. Pellizzari, however, on careful examination of the purulent contents of three peri-urethral abscesses, found only gonococci, and none of the recognized pyogenic microbes. The absence of such microbes and the identity of the organisms observed in the pus with the gonococcus of Neisser were proved by the failure to effect any cultivations on gelatine and other nutritive media. The gonococcus, it is well known, cannot be developed in gelatine, whilst, on the other hand, the ordinary pyogenic organisms are readily and quickly cultivated in

this medium. The case reported by Christiani, taken together with those of Pellizzari, favor the conclusion that in some cases of peri-urethral abscesses of gonorrhœal origin, gonococci are the primary agents of suppuration, and are not associated with other pyogenic micro-organisms until a late period, and after the formation of the abscess.—*Brit. Med. Jour.*

EPILEPSY FOLLOWING REVACCINATION.

J. Althaus (*Archives de Neurologie*) cites a case in which revaccination in a healthy youth of 19 caused attacks of true epilepsy. Great stress is laid upon the fact that the family and personal histories of the patient were excellent. In the commencement of June, 1888, he was revaccinated, having been previously successfully vaccinated when a baby. A week later there occurred a pustular eruption, severe lymphagitis and swelling in the right knee and tibiotarsal articulation. Emaciation set in, and at the end of the month he had his first attack of epilepsy. These seizures were attended with all the classical symptoms of that disease, and were of very frequent occurrence. In the month of May, 1889, he remained two months in Regent's Park Hospital, at London, where the attacks were first lessened and finally cured by use of bromide potassium, arsenic and hyoscyamine. Althaus has followed the subsequent history of this patient, and states that there has been no return of the attacks.

EXAMINATION OF SPUTUM.

Gabritschewsky (*Deutsche med. Woch.*, October 22d, 1891) advocates the examination of sputum in sections. Ad. Schmidt is stated to have been the first to employ this method, by means of which he was enabled to discover certain structures not to be seen is preparations of sputum made in the usual way. Cover-glass preparations are, in fact, insufficient, since many cells are destroyed by the process involved, and the histological nature of many others cannot be determined without preliminary fixation. As fixing and hardening fluids the author employed alcohol, Müller's fluid, Flemming's solution, picric acid, and sublimate in concentrated form. Each of these reagents is reliable, with exception of Müller's fluid. The freshly-expectorated sputum was allowed to fall directly into the hardening fluid. When hardened the mass was imbedded in celloidin, and so cut. Sputum which is simply slimy, without definite tenacity, is unsuitable for this mode of examination. The author stains his sections with safranin, alum-carmine, or hæmatoxylin and eosin. In three out of four cases of pulmonary tuberculosis he was able to demonstrate giant cells in sections of the sputum.—*Brit. Med Jour.*

DOUBLE SUBACUTE GLAUCOMA.

Before the London Ophthalmological Society, Critchett (*Lancet*, October 24, 1891) reported the case of a woman, 29 years old, in which, within twenty-four hours after a serve shock, there was felt intense pain in both eyes, with vomiting and loss of vision. The eyes soon became densely hard, the pupils dilated, and the media so hazy as to interfere with a satisfactory view of the fundus. There was doubtful perception of light. The results of operative interference were not encouraging, and it was at the urgent solicitation of the patient and her mother that a double iridectomy was performed. The wounds healed favorably, but the recovery of vision was gradual and slight. The discs subsequently showed moderate cupping. At the end of fifteen years little change had taken place.—*News.*

GANGRENE FOLLOWING HYPODERMIC INJECTIONS OF ANTIPYRINE.

Verneuil reported to the French Academy of Medicine, recently, two cases of partial gangrene of the dorsal aspect of antipyrine. In these cases the injections, had been administered in the vicinity of the region in which the pathological process occurred. The dose which was injected was not ascertained in either case. The character of the trouble for which these injections were given were in one case a wrench followed by pain in the thigh and leg, and finally in the toes; in the other case it was an aphyxia of the extremity accompanied by violent pain.

A BULLET IN THE SKULL FOR FORTY-THREE YEARS.

Saxer (*Corresp.-Blatt. f. Schweizer Aerzte*, September 15, 1891) reports the case of a soldier who, when twenty years old, was struck by a bullet in the region of the left mastoid process, the missile perforating the bone and remaining unextracted. The patient lived for forty-three years after the reception of the injury. For twenty years a sinus persisted, the wound suppurating moderately. The patient complained of pain and a sense of weight and boring in the head and noises in the ears; there were men-

tal confusion, impairment of memory, and other psychical symptoms. At the autopsy the flattened bullet was found imprisoned between the dura mater and the bone, in the midst of an inflammatory hyperplasia, behind and below the pervious defect in the bone. There was a permanent depression at a corresponding point in the left occipital lobe.

GASTROSTOMY IN CANCEROUS STENOSIS OF THE CARDIAC ORIFICE OF THE STOMACH.

Dr. Victor von Hacker, of Vienna, states (*Centralbl. f. Chir.*, No. 37, 1891) that he is opposed to Lauenstein's conclusion that extreme cancerous constriction of the cardiac orifice of the stomach is an absolute contra-indication to gastrostomy. Whilst recognizing the importance, from scientific and diagnostic points of view, of distinguishing concer of the lower part of the œsophagus from cancer of the cardiac orifice of the stomach, he holds that such attempts at localization have no bearing on the choice of treatment. He gives brief notes of six cases, which show that gastrostomy performed as a palliative plan of treatment may be attended with results just as good in cancer of the cardiac orifice, even when a tumor can be felt in the epigastrium, as in cancer of the lower end of the œsophagus. In comparing these six cases with nine other cases in which he performed gastrostomy for cancer of the œsophagus, he can find no difference between the two series with regard to the feasibility of the operation. The fistula was as readily established in one set of cases as in the other, and an equal prolongation of life was attained. In studying the details of his fifteen cases, von Hacker finds that the occurrence of more or less severe bronchitis has a most unfavorable influence on the results of the operation. Snch a condition, it is pointed out, occurs for the most part in cases of cancer affecting the œsophagus. In none of the above-mentioned cases was life much prolonged after gastrostomy. The author believes, however, that the operation serves to render the latter days of the patients more tolerable, for the troubles which, with continuous fruitless efforts to take food, are caused by the uninterrupted retching of mucus and by frequent vomiting, are very distressing. It is acknowledged that no good result can be expected from gastrostomy in cases in which the new growth has involved a large portion of the stomach, especially the greater curvature, and has probably contracted extensive adhesions with the surrounding tissues. Under such circumstances one would be able, as a rule, to make out the presence of a large gastric tumor. In ordinary cases, however, of annular carcinoma of the cardiac orifice the digestive function of the stomach is not much impaired, even when the new growth is almost as large as the first, and involves, to some extent, the lesser curvature. Under such conditions as these, gastrostomy may be performed with as good prospects of success as in cases of cancerous stenosis of the œsophagus. By the author's plan of operation, in which the fistulous opening is established in the middle of the rectus muscle, it is possible to bring the abdominal wall, which at this point is lax, into close contact with the small and retracted stomach. With the incision made close to the costal margin the surgeon might not always succeed in doing this.—*Brit. Med. Jour.*

PSEUDO-TUBERCULOSIS.

Professor Hayem reports this case: The patient was a youth, 17 years of age, without any hereditary history of tubercle, who had had typhoid fever at the age of thirteen. For several months prior to coming under observation a slight bronzing of the skin was noticed. This was followed by general malaise, with vomiting and all the signs of a febrile gastric affection. The temperature remained raised for several days, and then dropped. The patient then appeared to fall into collapse. The extremities were cold, temperature subnormal, and he complained of vague muscular pains and extreme weakness. A diagnosis of gastro-enteritis was made, but no cause could be discovered. The tongue was pale and furred; vomiting became more frequent; there was great thirst; the stools were normal, but sometimes diarrhœa occurred. Liver, spleen, and lungs normal; cerebral symptoms absent. The patient eventually died of cardiac collapse. Owing to the increase in the bronzing of the skin the diagnosis of Addison's disease was finally made.

At the autopsy the right suprarenal body was normal, but the left was found to be transformed into a grayish mass; the glands of the neighborhood were normal. The grayish mass was softened in the centre, which was surrounded by round cells. No tubercular nodules could bee seen, giant-cells were absent, and the search for tubercle bacilli was unsuccessful; but, on the other hand, the bacilli of pseudo-tuberculosis were

found. The stomach was normal. The intestines were somewhat inflamed, especially around Peyer's patches. The follicles, both isolated and agminated, were enlarged, and in them the characteristic bacilli were found; the blood also contained them. The lungs were normal. Cultures made from the blood, the intestine, and all the abdominal organs produced similar bacilli to those obtained from animals which had died of pseudo-tuberculosis. Inoculations made on animals from the cultures produced the disease. This is characterized by the formation, especially in the abdominal organs, of a condition which to the naked eye is precisely similar to miliary tubercle. Small nodules are formed, which under the microscope are seen to consist of collections of small rounds cells, surrounded by cells more epithelial in character; giant-cells are rare. The bacilli are extremely difficult to stain in the tissues, but cultures are easily made. The organism grows well on all the ordinary media, especially nutrient gelatine. In forty-eight hours at the ordinary temperature a luxuriant growth results. The bacilli are short, thick rods, appearing at first sight almost like diplococci. Under a high power, however, the rod formation is undoubted. The bacilli exhibit a great tendency to run together into rods; in fact, some authors have declared that the organism is polymorphous. Animals inoculated with a fresh culture die in from ten to fourteen days. Intravenous injections produce death in about forty-eight hours, without the formation of the characteristic lesions.

CAUSES OF ARTERIO SCLEROSIS AND ARTERIAL CARDIOPATHIES.

According to the *Mercredi Médical*, September 30, 1891, Dr. Huchard places the poisons of imperfect digestion among the many causes of arterio-sclerosis and arterial cardiopathies. Excessive meat diet, or game slightly cooked or of poor quality, throws into the economy numerous ptomaïnes that are imperfectly eliminated and are capable of producing poisoning effects hitherto ascribed to heart trouble, as vertigo, dyspnœa, etc. Such conditions are favored by renal insufficiency, that in turn becomes a cause of arterio-sclerosis. The town-dweller and the wealthy eat too much meat. Poor people and peasants eat less, but of such inferior quality that the result is the same, namely, an excess of ptomaïnes. For those showing predisposition to the troubles under consideration, well-cooked meat once daily, fresh vegetables in abundance, and milk, constitute an ideal diet.

SURGERY.

PUNCTURE IN CHRONIC HYDROCEPHALUS.

Dr. Karnitzky (*Arch für Ped.*, August and October, 1891) reports five cases of hydrocephalus treated by puncture. In none of the cases did any complication follow the operation. In two cases the child died; in one the head was tapped twice, in the other five times; in the latter death was due to diarrhœa, and considerable improvement followed the first tapping. In another case, tapped five times, the child was growing rapidly worse when last seen; one case was only under observation five days; in the fifth case, a female child eleven months old, with a very large head, with extremely thin bones, six punctures were made during the course of the month; the circumference of the head was reduced from seventy to sixty centimetres, and when at the end of this time the child ceased to be brought for treatment, it appeared to be doing well.—*British Medical Journal.*

THE SURGICAL ASPECTS OF A LONDON FOG.

During the week ending December 26th, which was characterized by a very heavy fog, the accident cases received at one of the London hospitals consisted of 51 fractures, 6 dislocations, 24 sprains, 4 concussions, 13 contusions, 50 lacerated scalp wounds, and 1 rupture of the globe of the eye. The minor casualties treated consisted of: Sprains or contusions of the shoulder, 23; of the elbow 13; of the wrist, 23; of the fingers, 12; of the hip, 9; of the knee, 10; of the ankle, 24; of the toes, 6; of the back, 18; of the side, 23; of the jaw, 2; 8 lacerations of the finger, 4 of the face, 8 of the scalp, 5 of the forehead. In twenty-four hours—December 25th and 26th—11 cases were seen of fractured radius, either with or without fracture of the ulna.

THE SUTURE OF NERVES.

At a meeting of the Berlin Medical Society, Gluck (*Deutsche med. Wochenschr.*, 1891, No. 46 p. 1273) presented a man twenty-two years of age who, following a punctured wound of the arm, developed complete radial palsy. Enlarging the wound, it was found that the muscular spiral nerve had been divided. The proximal and distal extremities were carefully sutured and the wound was closed. At the expiration of a month, electric treatment was instituted. At

the expiration of five months, reactions of degeneration were still present, but power of movement was beginning to return. A favorable prognosis was expressed.

STATISTICS OF EIGHTY-FIVE OPERATIONS FOR STRANGULATED HERNIA IN HOSPITAL PRACTICE.

Dr. F. A. Southam, says in the *Lancet*: It is a recognized fact that in hospital practice the operation for the relief of strangulated hernia is attended by a high rate of mortality, this being generally due to one of two causes: either (1) the delay which has been allowed to elapse before surgical interference is sought; or (2) the injury which has been previously inflicted on the contents of the hernia by forcible, prolonged, or repeated attempts at taxis. The consequence is that the condition of the bowel is such that it is frequently past recovery, even though the strangulation is relieved immediately after the patient's admission into hospital. This fact is well illustrated by the following statistics of 85 cases of herniotomy, which have been under my care in the Manchester Royal Infirmary during the past twelve years, in almost all of which the operation was performed shortly after admission:

	No. of cases.	Recovered.	Died.	Mortality.
Femoral	37	22	15	40.5 per cent.
Inguinal	36	22	14	38.8 "
Umbilical	12	3	9	75.0 "
Totals	85	47	38	44.7 per cent.

At first sight the proportion of fatal cases appears to be unusually great, but on comparing the results with those of other large institutions, I find that the average morality attending herniotomy in hospital practice varies from 32 to 46 per cent., if the three varieties —femoral, inguinal, and umbilical—are taken collectively.

Femoral.—Of the 37 cases of the femoral hernia, two occurred in males and 35 in females; 9 between twenty and forty, 17 between forty and sixty, and 11 between sixty and eighty years of age. From the above table it will be seen that 15 terminated fatally. In 1 case the bowel, though otherwise healthy, was found to be ruptured at the time of operation, as the result of taxis previously to admission. In four cases, all fatal, where the bowel was distinctly gangrenous, it was opened and left in the sac; in three of these the stricture was not divided, in one it was divided. In the remaining 10 fatal cases the bowel, though extremely congested, was healthy, and it was therefore returned into the abdomen; in one of these it gave way on the seventh day, and there was an escape of fæces from the wound, which continued until death on the fifteenth day. In another case a fæcal fistula formed a few days after the operation, and after being present for some time gradually closed, the patient completely recovering. In three of the successful cases, where all the symptoms of strangulation were present, omentum only was found in the sac, thus illustrating the fact that the the symptoms produced by strangulation of omentum are indistinguishable from those caused by strangulation of the bowel. In each instance removal of the mass of omentum was followed by immediate subsidence of all symptoms.

Inguinal.—Of the 36 cases of inguinal hernia, one occurred iu a female and 35 in males; two under two years—viz., seven weeks and eighteen months,—two aged eighteen years, 13 between twenty and forty, 11 between forty and sixty, and 8 between sixty and eighty years of age. From the above table it will be seen that 14 terminated fatally. In two of these, where the bowel was gangrenous, it was left in the sac, the stricture being divided; in another the gangrenous portion of intestine was resected.

Umbilical.—The 12 cases of umbilical hernia all occurred in females; seven between thirty and fifty, and five between fifty and seventy years of age. No less than nine cases terminated fatally, thus illustrating the very high mortality which attends operation in this variety of strangulated hernia. In nine cases the bowel was sufficiently healthy to admit of its return into the abdomen; in three cases, all fatal, portions of gangrenous intestine were resected, the ends of the bowel being brought together in two cases by sutures, in one by Senn's plates.

Cause of death in the 38 fatal cases.—In 10 the bowel was found to be gangrenous at the time of operation, and in one case ruptured as the result of previous attempts at taxis. In the remaining 27 fatal cases the bowel, though more or less congested and tightly constricted, was in a sufficiently healthy condition to allow of its reduction. In 16 of these, where a post-mortem examination was made, the bowel was found to have become gangrenous in four cases; in 10 cases it had ulcerated, and perforation had taken place at the line of construction. In one case there were evidences only of peritonitis; in another, where the cause of death was diabetic coma, the bowel itself as well as the adjacent parts were in a healthy state. In 11 cases no post-mortem examination was obtained, and the exact cause of death was therefore not made out.

Method of operating.—In every case the sac was opened, and for some years it has been my custom to perform a radical cure at the time of operation, provided the bowel is in a healthy condition. If, however, its condition is at all doubtful, the neck of the sac is not closed, and the external wound is left partly open, a drainage-tube being inserted in order to provide an outlet for the escape of fæcal matter in case the bowel should give way after its return into the abdominal cavity.

THE HEALING OF WOUNDS IN BLOODLESS OPERATIONS.

The after effects of the bloodless system of operating, as carried out by means of Esmarch's bandage, not having been very satisfactorily ascertained, Dr. Sokolovski of St. Petersburg, working in Professor Ivanovski's laboratory, has recently performed a large number of experiments for the purpose of ascertaining whether under this system the healing of wounds is at all altered or retarded. His plan was to makesimilar incisions or other wounds on the two hind legs of a dog or a rabbit. One of the limbs had been rendered bloodless by an elastic bandage, while the other was operated on without this precaution. Both wounds were dressed, and their subsequent progress compared both by ordinary and by microscopic observations. The regeneration of epithelial elements is brought about by the multiplication of the cells of the formative layer by indirect or partially direct division. Sometimes the wound becomes covered with an epithelial growth, which is inefficient, not being permanent, but undergoing degeneration. Generally the cells of the old epithelium at the edges of the wound undergo changes consisting in a diminished amount of chromatin, in consequence of which the nuclei are bright and stain badly, or the chromatin fibres become diminished in number, but are shorter and thicker; these changes do not, however, go as far as chromatolysis. Mitoses of the epithelial cells are mostly seen when the wound is covered with one or two layers of cells; sometimes, however, they occur in the cells of old epithelium lying in close vicinity to new cells. All the above processes take place in wounds, whether they have been inflicted on a bloodless limb or on one in its ordinary condition; but in the former case there is a marked retardation. If the bloodless condition of the part has not lasted more than three hours, the alteration in the cells is but slight, and confined to the superficial layer. When, however, it has persisted for a longer period, the cells of all the layers are affected, the nuclei becoming stellate, staining badly, appearing too bright, and having a deficiency of chromatin. The mitoses are diminished in a wound made in a bloodless part, and some of the karyokinetic figures are abnormal, the rays of the asters being irregular or shortened and thickened—*Lancet.*

A BULLET IN THE BRAIN FOR TWENTY-NINE YEARS.

Conniff (*Vis Medicatrix*, i, 5, 1892 p. 279) has reported the case of a man, sixty-three years of age, whom he was called to treat in an attack of enteritis. There was, besides, a history of pain in the head and an inability to lie on the right side. Inquiry elicited the fact that twenty-nine years previously the man had received a gunshot wound at the left angle of the mouth, the bullet, it was supposed, entering the brain. The patient maintained that upon rotating his head he could feel the missile just back of the left ear. He suffered almost constant headache, at times most intense and attended with vertigo. Hearing was lost on the right side. Vision was impaired on the left. The patient died, and at the autopsy, in addition to the lesions of a plastic enteritis, a bullet was found imbedded in the occipital lobe of the left cerebral hemisphere, behind the posterior cornu of the lateral ventricle. The bullet had entered near the left angle of the mouth, passing beneath the malar bone and entering the cranium through the left orbital cavity close to the optic nerve; thence it had passed toward the left lateral sinus.—*News.*

THE POSTURE OF THE PUERPERAL PATIENT.

Duke (*Medical Press*, 1892, No. 2753) considers the usual custom of keeping the puerperal patient upon her back for a long time after labor to be most injurious. He claims that drainage of the birth-canal is least thorough in this position and that retro-displacements of the uterus frequently result from this custom. He favors the semi-recumbent position upon the hip or the sitting posture for a few moments after the first twenty-four hours. These positions favor involution and promote the action of the bowels. The best posture to favor the delivery of the placenta is the prone position, and the puerperal patient should assume this posture for a short time daily.

THE RADICAL TREATMENT OF PROSTATIC HYPERTROPHY.

Dr. K. Eigenbrodt presents the following conclusions on this subject, which are based upon an experience of five cases and a thorough study of the literature of the operative treatment:

1. Observations have shown that in most cases of obstructing hypertrophy of the prostrate a radical operation is perfectly feasible. This consists in a suprapubic prostatectomy, by which all the protrusions at the vesical neck due to the enlargement of the prostate should be removed, if this is possible.

2. Prostatectomy gives the best results if performed at an early period, and early operations before the occurrence of cystitis would be indicated in all cases if it were possible to prevent the development of a cystitis due to the operation itself.

3. Even in advanced cases we can sometimes effect considerable improvement and even a restoration of the function of voluntary urination.

4. In cases apparently cured by the radical operation great attention should be paid to the persisting weakness of the bladder (residual urine), and when necessary the patients should be treated for this condition and kept under observation.

5. In obstructing prostatic hypertrophy, the obstacle to urination is not so frequently due as is generally believed, to a valve-like occlusion of the urethral orifice by a prominent lobule or wall at the vesical neck. Much more frequently this is caused by a general and uniform enlargement of the vesical end of the prostate, in connection with the formation of a *cul de sac* in the bladder. If during the performance of prostatectomy, in the latter case, everything that protrudes into the bladder cannot be removed, we should attempt to secure a free passage for the urine by a *wedge-shaped*, deep excision at the posterior margin of the internal urethral orifice.—*Beitrage zur Klinischen Chirurgie, Bd.* viii, *Hft.* 1.

CATHETERIZATION OF THE FEMALE BLADDER.

Professor Parvin advocates the use of the ordinary male catheter, instead of the female, as by its greater length the bladder can be emptied without soiling the clothes or necessitating any exposure of the patient. It is passed into the bladder just as easily as the other kind.—*Coll. and Clin. Record.*

OBSTETRICS.

CÆSAREAN SECTION.

Bogdanik, of Biala (*Centralbl f. Gynäk.*, No. 6) was called in, on September 11th, 1891, to a woman, aged 40, in labor at term. She had already borne twelve children. She was much emaciated and a fœtid discharge issued from the vagina. Hard carcinomatous masses were detected in the vagina, extended as low down as the meatus. The cervix was extensively involved, and the point of the finger could hardly be passed into the os externum. Fœtal heart sounds were audible though weak. The patient had suffered from profuse flooding four months previously, but how long the cancer had existed could not be ascertained. In order to save the child and relieve the mother, Cæsarean section was performed. Tho operation was undertaken in a very small room in a cottage in a remote German-Polish village. The patient was first put under the influence of a mixture of equal parts of chloroform and ether; the charge of the anæsthetic was then entrusted to a country midwife. The abdominal walls were washed with soap and carbolized water, and compresses soaked in the same solution were laid over the vulva. An asphyxiated child was delivered; it soon recovered. The cord was tied in two places and the placenta removed. The uterine cavity and the operation wound were washed with carbolic solution, then the uterine wound was sutured after Sänger's method. A continuous sublimate catgut suture was employed. Iodoform powder was strewn over the uterine cavity and the peritoneum as well as the external wound, which was dressed with iodoform gauze. The mother lived a fortnight, dying of exhaustion; the child, a well-nourished girl, was saved. Bogdanik maintains that Cæsarean section, like herniotomy, is an operation that any practitioner may be called upon to perform, sometimes under unfavorable surrounding conditions.

Eckerlein, of Königsberg (*ibid.*, No. 8, 1892) gives details of a Cæsarean section in a patient aged 39. Her last period occurred at the end of October, 1889; the fœtal movements were first felt in the first half of March. During the first three months there was much vomiting. She had never been pregnant before. The waters broke on August 24th. Three days later the pains set in; they lasted four days, yet the labor made no progress. The child was very large and evidently dead, the pelvis flat, and uni-

versally contracted. The uterus was tympanitic on percussion. On account of the narrowness of the pelvis, the size of the fœtus, and the great wish of the mother that she might bear a child on a subsequent occasion, Cæsarean section was determined upon, in preference to craniotomy or Porro's operation. Sänger's procedure was strictly carried out. The uterus contained much fœtid gas. A towel soaked in a 4 per cent. boracic solution, was passed behind the uterus. An elastic ligature could not be brought round the cervix, as the head of the fœtus filled the pelvic brim. The uterus was drawn well to the right, and its anterior surface slightly twisted to the right. A long incision was made, and a putrid fœtus extracted. Contractions following and the placenta was expelled. The uterine cavity was stuffed with a long strip of iodoform gauze, soaked in a 5 per cent. solution of carbolic acid. Uterine contractions came on on the third day, but ceased when the gauze was removed. An abscess formed in the abdominal wound. The patient ultimately recovered.—*Brit. Med. Jour.*

THE INFLUENCE OF PREGNANCY ON EPILEPSY.

A very exhaustive article by Dr. Guder on this subject is carried through two numbers of the *Medicinish-chirurgisches Centralbl.* The author has made extended research into the data bearing on this question. This, taken conjointly with his own personal experience of such cases, enables him to draw the following conclusions: That epileptic attacks were, as a rule, absent during pregnancy, but that they were always sure to make their appearance during and after the puerperal period; that there was the fact of the offspring of such women being predisposed to epileptic or eclamptic attacks, to be taken into consideration. For his part the author was disposed to persuade, as far as possible, epileptics from marriage and that if pregnancy did occur he was in favor of artificial abortion. He thought that an effective means of stamping out, or at any rate of preventing children being born with a predisposition to epilepsy, would be the sterilization of epileptics by castration or ligation of the tubes. As to the predisposition of epileptics to eclampsia there was still a great difference of opinion among observers in this direction. Nerlinger thought that for one thing a differential diagnosis of an attack, occurring during the puerperal state in an epileptic, was difficult to make, as to whether it was an epileptic or eclamptic seizure, and that as to the question of predisposition of epileptics to eclampsia the matter was by no means settled. And also that in young children predisposed by neurotic inheritance to epilepsy it would be a difficult matter to say whether the first attack was epilepsy or eclampsia. Fere thought that there was a close association, in predisposed neurotics, between epilepsy and eclampsia.—*Journal of Nervous and Mental Diseases.*

GENEVA CHEMISTS AND THE PRESCRIPTION.

Geneva chemists have to keep the prescriptions which they dispense. The reason for this is explained by Mr. A. Cordes in the *Lancet* as being the fact that about twenty-five years ago a nurse obtained a prescription for atropia. With that prescription she went from one chemist to another, and got large quantities of this drug, with which she poisoned many of her patients. She was tried and condemned. The authorities deemed it prudent to pass a law obliging the chemist to keep the prescriptions, thinking by it to avoid any crime of the sort in the future.

GYNÆCOLOGY.

LAPAROTOMY UNDER COCAINE.

Dr. Emory Lanphear, in a paper read before the Kansas City Acad. Med., said:—

There are, many times, patients who require abdominal section yet who are in such physical condition as to almost absolutely prohibit the administration of either chloroform or ether. In such instances the surgeon may without hesitation make the operation under the effects of cocaine. The following is an instance:

Mr. W——, age 52, patient of Dr. F. R. Wheeler, of Sawyer, Kansas, was admitted to All Saints' Hospital suffering from a cancerous tumor of the left side of the neck, of very rapid development. Patient began to experience difficulty in swallowing about nine weeks ago, when his weight was 165 pounds. The dysphagia increased at an alarming rate and two weeks before admission to the hospital it became a matter of impossibility to swallow at all. Partial removal of the tumor was done by Dr. Wheeler and McCoy (of Pratt, Kans.), under local anæsthesia, it being deemed inadvisable even at that date to use chloroform or ether. There was very little improvement, so the patient was brought to Kansas City to the hospital for further treatment.

When admitted he was *in extremis,* weight less than 80 pounds and at the gate of death from starvation. Upon the evening of admsssion the abdomen was carefully scrubbed and shaved and a pad of moist bichloride gauze applied. At 9 A. M. on the following day, assisted by Drs. J. F. Binnie and T. B. Thrush (Dr. Sawyer standing ready to administer ether if it should be required), I made a gastrostomy under local anæsthesia from cocaine. One-half dram of a 4 per cent. solution was injected in eight places into the subcutaneous areolar tissue along the proposed line of incision. As soon as the analgesic effect was established the usual operation was made, and without any pain or even sense of discomfort on the part of the patient. The only disagreeable symptom was a slight nausea when the left lobe of the liver was turned up to allow the stomach to be drawn up into the wound. The operation lasted 22 minutes. How much longed the operation might have been prolonged without discomfort to the patient is a question of interest. But as a large number of the abdominal operations can be made within twenty minutes it is not so important as might be supposed. Besides the fact that the primary depressant effect of a general anæsthetic was avoided by the use of cocaine, there were two other points of much importanee in this case, viz., the absence of the vomiting that nearly always follows chloroform or ether, and especially the *absence of shock.* There was a total absence of anything like shock, and if this be found to be a general rule an immense gain may be made in sewing up stab or even gunshot wounds of the intestine (as well as in other numerous abdominal operations), by the use of local instead of general anæsthesia.

FIBROID TUMOR OF THE FALLOPIAN TUBE.

Spaeth (*Zeitschrft f. Geburtsh. u. Gynäk.,* vol. xxi, pt, 2, 1891) describes a case where a woman suffered from frequent vomiting and continual pain in the left side. Abdominal section was performed and a tumor was removed after the separation of peritoneal adhesions. At the operation it was found that the left tube ran into the growth ; afterwards, when the tumor was examined, it was found to consist of a uniform hypertrophy (1½ inch thick) of a tubal well. Two-fifths of an inch of the uterine half of the tube remained attached to its inner aspect, whilst the abdominal end hung from its outer side. On microscopic examination the tumor proved to be a fibromyoma, and there was no evidence of inflammation. The existence of a myoma on the tube is easy to understand, for the tube is developed from Müller's duct like the uterus, an organ very subject to myoma. Nevertheless, myoma of the tube is exceedingly rare.—*British Medical Journal.*

EXTIRPATION OF UTERUS FOR SLOUGHING SUBMUCOUS FIBROID.

Demetrius von Ott (*Volkmann's Sammlung klin. Vorträge,* No. 34, 1891) considers that suppurative disintegration of a submucous uterine fibroid is best treated by total extirpation of the uterus, which alone can insure the complete elimination of the infected area. Whenever there is any reason to suspect that the adjacent peritoneum has already become affected, special care must be taken to allow for drainage through the communication established at the operation between the vagina and peritoneal cavity. In cases of gangrenous destruction of a fibroid in the uterine cavity, the condition of the appendages must be made out as accurately as possible, so that the surgeon may decide upon how to dispose of them, and may add to our experience of their condition and the necessary treatment in this grave complication.—*Brit. Med. Jour.*

PÆDIATRICS.

THE TREATMENT OF CROUPOUS PNEUMONIA IN CHILDREN.

S. H. Dessau (*Arch. of Pædiatrics,* September, 1891) says the main danger to life in croupous pneumonia arises from the circulation; hence the physician's chief efforts should be directed to correcting this mechanism. Other influences, such as the effects of the disease poison, should also be taken into consideration. A pulse of 160, with temperature 104° to 105° F. at the onset indicates that the disease is of a serious character, but this alone does not always indicate an unfavorable termination. High temperature may, however, lead to convulsions in children, and antipyrin may thus be sometimes found of great service. Apathy, with inability to hold up the head in the early stages, is of unfavorable significance. The amount of albumen in the urine has also a definite relation to the mortality. The extent of lung tissue involved may bear no relation to the danger of heart failure, but when both lungs are involved few cases recover. A natural termination begins suddenly with profuse perspira-

tion, caused by sudden return of blood to the cutaneous vessels; the indication seems therefore to be for diaphoretics, such as nitrites, Dover's powder, etc. In more serious cases a warm bath, at 95° F., or hot sponging, etc., may be employed for the same purpose. For the more sthenic cases recourse may be had to the "ice cradle," or wet pack. The dilatation of vessels produced by one of the above methods will both relieve pulmonary congestion, and perhaps aid the excretion of some of the disease poison. The liver has an immense blood-holding power, and a way of making use of this to relieve pulmonary engorgement is to stimulate its function. The moderate use of calomel (one-tenth of a grain every hour for six doses, and every three or four hour afterwards) will often produce excellent results. The idea of obtaining any action on the lung by increasing absorption of the plastic exudation must be laid aside, for this is not the object to be desired. Aconite may also be of service given at the onset in hourly drop or half-drop doses; it slows the pulse, and gives the ventricle a longer time for its diastole. The frequent use of digitalis in croupous pneumonia is based on entirely false principles, for it has a tendency to diminish the vascular area; its action is to empty the arteries into the veins and not the veins into the arteries, as is desired. It stimulates the left heart, which has already an undue advantage over the right heart. Carbonate of ammonia is also condemned, the stimulant expectorant effect tending to convert an otherwise favorable case into a fatal one. Large doses irritate the stomach, and thus also diminish the chances of recovery. Locally, poultices may be useful as an aid to diaphoresis. A "warm wet binder" is a convenient and preferable substitute. The ice bag may be of service in strengthening the heart, but it must be used with care in children, as it often produces collapse.—*Brit. Med. Jour.*

SEAT-WORMS.

Success in the treatment of cases of seat-worms depends upon the prolonged and constant use of a vermifuge or some active vermicide. The worms are generally attacked by means of injections, suppositories or ointments. Of the injections, a favorite prescription is a solution of common salt in the proportion of one to five. Sometimes sugar and water may be used, and an infusion of absinthium is employed by some French practitioners. Still others employ simply cold water. It is said that West and Barthez recommended astringent injections composed of the perchloride of iron and lime-water, as follows:

℞ Lime-water ..... f ʒiv.
Perchloride of iron ..... gtt. x. M.

Rossbach used, with excellent results, the following:

℞ Naphthalin ..... gr. xv.
Olive oil ..... f ʒiss. M.

Trousseau is said to employ the following suppositories:

℞ Hydrarg. chlorid. mit ..... ʒi.
Vaseline ..... ʒiij. M.

When the worms inhabit the higher portions of the rectum they will probably resist all therapeutic measures unless they be attacked through the stomach. Under these circumstances it may be well to employ calomel and santonin, of each one-half grain, which is to be administered early in the morning in order that the calomel may act by evening. This dose is the proper one for a child of two to three years.—*Revue Génerale de Clinique et de Therapeutique.—Med. News.*

DEATH AFTER VACCINATION.

A case is reported in the *Lancet* for January 30, 1892, of an eight-months' child, weighing when born four pounds and three ounces, which was vaccinated eight days after birth, and died some thirteen days later. Cold cream had been applied to the arm by the mother, and the sores had not healed. There was a slight lung affection found at the post-mortem, but death was undoubtedly accelerated by the vaccination.

ETIOLOGY OF DIPHTHERIA.

Baginsky, in a study of 93 cases of diphtheria, found Löffler's bacillus in 68 cases, equal to 73 per cent. Of these 68, 27 died. In the 25 cases in which the bacilli were not found, but which, microscopically, gave indications of diphtheria, only one died.—*Archiv. für Kinder.*, Berlin, Nos. 1, 3, 4, 5, 6.

LEAD POISONING FROM PAPER HANGING.

Dr. Guyot reports (*Progrès Med.*, Nov. 28, 1891) the case of a servant girl attacked by lead paralysis of the four extremities. The source of the lead was undiscoverable. The patient went from her country place to the city home of her master. Here she recovered. On her return she was again attacked by the paralysis, as also was a servant room-mate. Analysis of the paper hangings revealed great quanties of lead. Dr. Labbé, in the discussion of the case, said that lead paralysis occurred among paper-painters.

HYGIENE.

EFFECT OF DEEP INSPIRATION ON THE ASSIMILATION OF FAT.

Acting on Professor Chudnovski's advice, Dr. A. Pavpertoff has made a series of observations on the effect of deep or forced inspiration and expiration on the assimilation of the fatty matters contained in food. The observations were made on nine healthy young persons, some of them being carried out in winter, others in summer. The sittings were held in a large and well-ventilated room, each subject making from 120 to 200 forced inspirations and expirations. By analyses of the fæces during the three periods —before, during, and after the forced inspiration—it was found that the amount of fatty acids in the fæces in all cases diminished during the second period, the average diminution being 1.246 per cent. In the third period the quantity of fatty acids as compared with that excreted in the first, diminished slightly in some cases, and increased slightly in others. All that can be stated therefore as the result of the experiments is that a slight increase in the assimilation of fat takes place while forced or deep respiration is going on. The above research is published as a "preliminary note" in the *Vrach*, No. 6, 1892.—*Lancet.*

PROPHYLAXIS OF INHERITED INEBRIETY.

At the quarterly meeting of the Society for the Study of Inebriety held at 11 Chandos Street London, on Tuesday, 5th inst., Dr. Charles Hare presiding in the absence of Dr. Norman Kerr, a paper was read by Mr. James Stewart, F.R.C.P.Ed., of Clifton who said they could not too often as scientific men protest against the use of the words drunkenness and inebriety as if they are convertible terms. M. Trelat had put the difference very clearly thus: "Drunkards are people who drink when they find any opportunity of drinking. Dipsomaniacs are diseased persons who get drunk whenever their attack seizes them." The drunkard, continued the lecturer, if he continues his vicious course might so injure his brain structurally or functionally that he would eventually become an inebriate. The inebriate, on the other hand, was an individual who was in most cases born with an unsound brain. He might even be a man who had never so much as tasted any alcoholic drink in his life. True, the disease might be acquired, but the experience of fifteen years had taught him that the neurosis was in most cases an inherited one. The neurosis often led the sufferer to seek relief by the narcotism of alcohol, and so cause and effect were greatly mixed up. Admitting, as we all must, that it was a transmissible cachexia, the question arises how best to prevent the germs of the inherited disease from being developed.

Dr. Joseph Parrish had said "inebriety might descend as inebriety, but it was just as likely to change the form of its appearance into insanity or other allied manifestation." Bearing this in mind, it is important that the child of an inebriate should be kept free from what might upset the nervous equilibrium, care being specially taken that the surroundings during early years were bright and calculated to develop the higher and nobler characteristics of the individual. He deprecated especially corporal punishment at the hands of strangers. He advised the mother, if her husband had been inebriate at the time of her child-bearing, to not only bring up her children as total abstainers, but, by telling them after puberty of their terrible inheritance, to warn them against ever touching alcoholic drink all their lives. The neglect to give this warning, the keeping back of this knowledge, had in some cases treated caused reproaches to be uttered against the mother for omitting to perform a duty to her child out of a desire to shield the memory of her husband. But if this duty was imperative in the case of a son, how much more so in the case of a daughter if either parent had suffered from the disease. If she is to marry, she ought to be warned as to the danger of marrying anyone whose family history was tainted with a neurotic inheritance—a danger enormously increased if she should marry a first cousin.

The lecturer concluded by the following summary of his views: 1. Drunkenness is a vice, inebriety a disease; the two terms must not be confounded. 2. The disease of inebriety once established may be transmitted to the patient's offspring either in the form of the alcoholic diathesis, epilepsy, chorea, insanity, or even tendency to crime. 3. The child of an inebriate born after the functional or structural lesion has been established is sure to inherit some nervous diathesis. 4. The only security against this diathesis developing as inebriety is by lifelong total abstinence on the part of the child. 5. Even the adoption of this precaution will not absolutely make certain that there will be no transmission of the cachexia by the child to his or her offspring. 6. To prevent the development of

the alcoholic neurosis in other directions—such as epilepsy—sudden excitement of the emotions and sensibilities, such as might be produced by corporal punishment by strangers, should in all cases be guarded against. 7. In the prophylaxis of inebriety the principle to be acted on with regard to children's training is that if we accentuate the good we attenuate the evil. 8. The marriage of the child or even the grandchild of an inebriate to a first cousin should be absolutely interdicted.

MEDICAL CHEMISTRY.

TINCTURE OF OPIUM IMPROVED.

Prof. Oldberg, in the *Apothecary* alludes to some tincture of opium made under his observation by R. B. Morrow of the Illinois College of Pharmacy, in which the opium was exhausted by warm water used in two portions, and the alcohol added to the water solution. The marc, when tested, gave no indications of alkaloids. It is claimed that warm water will readily exhaust all the useful constituents and leave most of the nauseous and odorous principles. The proportions of the liquid solvents were changed at the trial to nine parts of water and one part of alcohol, and it is claimed to be a change for the better in every respect.

QUININE HYDROCHLORATE.

The neutral hydrochlorate of quinine, official in the United States and various other pharmacopœias, crystallizes in white needles which are usually united in bundles, and which contain, when uneffloresced, 2 molecules of water of crystallization [$C_{20}H_{24}N_2O_2HCl.2H_2O$=396.4]. This water of crystallization escapes easily at 120° C. without causing the salt to melt. The melting point of the salt lies at 158° to 160° C., and even then the alkaloid does not suffer decomposition.

If an aqueous solution of salt, saturated at 15° C., is set aside for some time at a low temperature (0° C.), it happens sometimes that in place of the well-known long, asbestos-like needles there are formed large octahedral crystals belonging to the monoclinic system. On dissolving these crystals in water considerable short of saturation, and allowing the liquid to cool, the same kind of crystals are sometimes reproduced.

It was first supposed (by O. Hesse, from whose paper on this subject in Liebig's *Annalen*, 267, 142, we take this notice) that these crystals were due to the presence of an impurity of the quinine salt. But it was soon ascertained that they differed from the ordinary hydrochlorate of quinine merely in the amount of water of crystallization, containing 3 molecules instead of 2.

Acid Hydrochlorate of Quinine, which salt is especially useful for hypodermic purposes, is best obtained either by decomposing the acid sulphate of quinine (disulphate or "bisulphate of quinine) with an equivalent quantity of barium chloride, or by adding to a solution of the neutral hydrochlorate in water 1 molecule of hydrochloric acid. On evaporating either of these solutions at a gentle heat, the acid salt will separate, at a certain temperature, either in white, concentrically grouped needles or as a gelatinous mass. The latter gradually passes into the crystalline form, particularly at a gentle heat. But in either case the resulting dihydrochlorate is *anhydrous*. The crystallized salt (that is, the salt which separated in crystalline groups) may be dried up to 110° C. without undergoing any change; the gelatinous salt, on the other hand, when thus dried, becomes white and opaque. The crystallized as well as the hyaline salt, after it has become opaque, yields, upon being triturated, a powder which reflects sunlight with a distinctly blue tint.

REACTION FROM AN AQUEOUS EXTRACT OBTAINED FROM BACTERIA.

Roemer (*Wiener klin. Wochenschr.*, No. 45, 1891, p. 835) has recorded a series of experiments made with an aqueous extract obtained from cultures of the pneumonia-bacillus and the bacillus pyocyaneus. Three guinea-pigs inoculated six weeks previously with the fluid obtained from tuberculous lymph-glands died shortly after having receiving injections of the extract. The injections were in each case followed by elevation of temperature. Post-mortem examination disclosed, in addition to the evidences of tuberculosis, enlargement of the lymphatic glands, serous effusions, and injection of and hæmorrhage in various viscera. Injections in three healthy animals were followed only by elevation of temperature.—*News.*

A NEW AND RAPID TEST FOR SUGAR.

At a meeting of the Austrian Surgical Society, Professor Nothnagel showed a handy test for sugar, which had been forwarded to him by Dr. Becker, of Cairo. It is simply a visiting card saturated with a solution of potash, part of which is coated with sulphate of copper, and the urine applied. The card

is then laid in the globe of a lamp, when the saccharine urine will color the card brown, and this color will be the deeper the greater the amount of sugar.

NEWS AND MISCELLANY.

MEDICAL READING PARTIES.

Dr. J. A. Campbell, of Carlisle, has recently, in the pages of the Edinburgh *Student*, proposed a plan for the utilization of county hospitals and asylums for teaching purposes during the summer months. A young graduate, Dr. Campbell suggests, might act as reading tutor in charge of a party made up principally of third year's students, who could attend a provincial hospital and an asylum if convenient. Such attendance and clinical instruction could, it is thought, be easily arranged, and probably vaccination and attendance on midwifery cases could also be obtained. There can be no doubt that Dr. Campbell's idea is good. Independently of idle students who cannot be made to work, and of young men of determined and methodical character who work in term time and make it a rule to enjoy themselves during the holidays, there remains a type of student who soon becomes sated with his vacation. The curriculum is short, and such a student may wish to make the most of the two or three years of tutelage left to him when he begins his clinical studies. The utilization of asylums in the manner suggested would, perhaps, present difficulties. The county hospital is a simpler matter, but though the chief difficulty is simple enough, it is none the less a difficulty. County hospitals with about a hundred beds usually have a dressing staff of their own. First-rate pupils are yearly turned out of the hospitals at Brighton, Exeter, and elsewhere. Besides, the reading party would in many cases be forestalled, as it is the custom amongst many students in London hospitals to seek dresserships in country hospitals, and they often prefer the vacation to dress in, as such an arrangement does not interfere with lectures and classes at the London school. Vaccination and attendance on midwifery would involve careful arrangements with local practitioners and midwives. No doubt, with a little determination all difficulties could be overcome. The party might arrange to go round wards with a medical officer of a country hospital, and could thus learn much even if they were not suffered to be full dressers. A certain amount of pathology could be studied, and in other respects the reading party could combine instruction with recreation. Perhaps, too, the sanitary authorities might aid them, for a consideration, in learning the rudiments of health administration.—*Brit. Med. Jour.*

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

The Forty-second Annual Meeting will be held in Harrisburg, on Tuesday, Wednesday, Thursday, and Friday, May 17th, 18th, 19th, and 20th, 1892, commencing on Tuesday, May 17th, at 9 A. M.

APPOINTMENTS FOR 1892.

1. Address on Practice of Medicine.—Dr. J. H. Musser, Philadelphia.
2. Address on Surgery.—Dr. T. D. Davis, Pittsburgh.
3. Address on Obstetrics.—Dr. H. G. McCormick, Williamsport.
4. Address on Mental Disorders.—Dr. J. W. Phillips, Clifton.
5. Address on Otology.—Dr. G. R. Roher, Lancaster.
6. Address on Hygiene.—Dr. A. A. Woods, Erie.

TO BE ACTED UPON.

Report of Committee on Pharmacy.—Dr. H. A. Hare, Philadelphia, Chairman.

Report of Committee on Contagious Ophthalmia.—Dr. J. A. Lippencott, Pittsburgh, Chairman.

Report of Committee on Rush Monument Fund.—Dr. W. Murray Weidman, Reading, Chairman.

Chairman of Committee of Arrangements.—Dr. Wm. T. Bishop, 211 Pine Street, Harrisburg, to whom all applications to read papers at this session should be sent not later thon April 1st.

Secretaries of County Medical Socities are earnestly requested to forward at once complete lists of their officers and members, giving the post office address of each.

Every delegate, before admission, shall present a certificate of delegation, signed by the President or Secretary of his County Society.

Every permanent member (not a delegate), before admission, shall present a certificate of good standing in his County Society.—[Extract from Constitution.]

WM. B. ATKINSON,
Permanent Secretary,
1400 Pine St., Philadelphia.

The railroads will sell excursion tickets on card orders. All who desire orders should notify the Permanent Secretary, stating which railroad must be used.

Farbenfabriken vorm. Friedr. Bayer & Co.'s Pharmaceutical Specialties

ARISTOL Antiseptic: Cicatrisant.

EUROPHEN Iodoform Substitute: Antisyphilitic.

SULFONAL-BAYER Hypnotic: Sedative.

PHENACETINE-BAYER Antipyretic: Analgesic.

PHENACETINE-BAYER is a true and distinct organic derivative. It is indicated in influenza (*la grippe*); in all fevers, with or without pain; in rheumatism and neuralgia; and in phthisis and pertussis. It acts promptly and is both safe and effective. Supplied in ounces, tablets and pills.

EUROPHEN, as a substitute for iodoform, is winning an enviable place in therapeutics. It has a special value in specific lesions, while as a surgical dressing in ulcerations, open wounds, and septic conditions of the cavities, it has given excellent results. Supplied in ounces.

SULFONAL-BAYER is indicated in all the insomnias and in the cerebral disturbances of insanity. It is a pure hypnotic, a safe and effective remedy, and it does not give rise to a drug habit. For the correct method of administration *see pamphlet*. Supplied in ounces, tablets and pills.

ARISTOL is widely esteemed by physicians for the excellent results it has given in the treatment of all external traumatisms; in cavital lesions, and in many of the dermatoses. As a surgical application, it is safe, inodorous and non-toxic. Supplied in ounces.

EUROPHEN-ARISTOL, a preparation consisting of equal parts of each medicament, is also supplied in ounces.

DESCRIPTIVE PAMPHLETS FORWARDED ON APPLICATION.

W. H. Schieffelin & Co., New York.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels are:

1st—In quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the Proportion of Oil it contains.

3d—In mode of manipulation and thorough incorporation, rendering it Permanent and Palatable, and of proper consistence, about that of Rich Cream.

4th—In Size of Bottles, containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

ESTABLISHED 1830

JOHN C. BAKER & CO., Philadelphia.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

CLINICAL LECTURES.

EARLY ARTHROPATHIES IN TABES DORSALIS.

By PROFESSOR CHARCOT,
PARIS, FRANCE.

A CLINICAL LECTURE DELIVERED AT THE HOSPICE DE LA SALPETRIERE.

Gentlemen:—I will to-day call your attention to an extremely interesting and instructive case. It is a syndrome dependent on a progressive locomotor ataxia, and which appears under such special circumstances that it requires, in the first place, a minute examination, and, secondly, a knowledge of the various aspects under which the malady makes itself manifest, in order to establish a diagnosis.

Before entering into a discussion of this case let me go over some of the general characters of tabes dorsalis. I place before you upon the board the list of symptoms which I call the *tabetic series* ; they are about 18 or 20, and their combined variety represents all the clinical points of tabes.

The classical type of the disorder as described by Duchenne is, of course, exceptional, and regarding ataxia the anomalous characters of the affection constitute the rule, especially at the very onset. It is for this reason that I proposed, some time ago, to call *locomotor ataxia* by the name of *tabes*, for, strictly speaking, an ataxis disorder may exist, for many years, without any loss of co-ordination of movement ; sometimes it never exhibits any motor disturbances, as I found recently in a post-mortem examination.

Although the various symptoms may appear in a variety of combinations, they follow ordinarily the order pointed out by Duchenne ; that is, we have first the prodromic period characterized by lancinating pains, ophthalmic disturbances (myosis, diplopia), and some vesical troubles which may come on periodically. These symptoms may last for four or five years or even more.

It would be convenient to call this period, the period of lancinating pains, but there is still a better denomination, the one given by Fournier in his remarkable work upon the subject ; that is, the *pre-ataxic period* which answers very well to the conditions exhibited. Such does not always occur in Duchenne's type of the disorder, and hence the difficulties from a clinical standpoint. You must remember this fact ; not one of the 18 or 20 symptoms of the tabetic series, by itself, explains the condition.

I will bring to your notice some examples : A patient comes to you complaining of a weakened condition of the eye-sight; there is achromatopsia and, on ophthalmoscopic examination, you discover an atrophy of the disc. You will have no difficulty in recognizing the existence of tabes, although there may be other symptoms, because the tabetic disc is extremely characteristic of the disease, and is sometimes the only sign manifest, preceding, for several years, the other symptoms of tabes. Another example: A man who has always been apparently healthy awakes at midnight taken suddenly with a feeling of great depression; he suffers from suffocation, is restless and exhibits a sort of laryngeal whistling sound. The crisis passes in a few hours, to be repeated the following nights, until a permanent snoring sound of the voice is produced. This is, then, a laryngeal crisis which may go on increasing for a considerable time before any of the other symptoms of the malady are made manifest. What I have just said of the laryngeal crisis may be similarly applied to the gastric troubles that I have at other times described. You

are familiar with these painful attacks, accompanied with gastric disturbances such as vomiting, loss of appetite and general depression deepening into collapse, which come on suddenly without any apparent cause; they last a variable time and disappear after one or two months, during which time the digestive functions are again re-established. Under these various insidious aspects of the malady, often interpreted as purely gastric or hepatic troubles, is hidden a tabes dorsalis. I recall the case of a patient that came under my observation some time ago, who complained of rectal pains likened to those produced by an introduction of a hot iron or a forced dilatation of the sphincter. These anal crisis, as I call them, had been unrecognised for a long time and were considered of no diagnostic value by the different eminent surgeons consulted by the patient. The nature of the disorder was made clear by the appearance of lancinating pains and other symptoms peculiar to tabes.

These are not the only symptoms included in our series. You will find under the name of trophic disturbances, fractures, arthropathies, and the falling out of teeth and finger nails. Is it possible for the trouble under consideration to appear primarily? Yes, and the case which I will submit to your study shows that the disease began by serious articular lesions. Its history is very simple.

Although not always, syphilis is a frequent cause of this affection and, therefore, I would advise you to examine the question of the acquired or inherited constitutional disorder. In the present instance we have the history of an alcoholic parent. I have told you before that every drop of seminal fluid, in an alcoholic man, contains, in germs, the entire family of the neuropathies. Further, the grandfather, on the paternal side, had convulsive spells the nature of which we have not been able to make perfectly clear. The patient himself has never been sick; he is neither syphilitic nor of alcoholic habits. He is 28 years old, married, his occupation being that of worker in bronze, which has permitted him to live in good conditions.

What has been the origin of the symptoms in the man under our observation? In September last he went to take a course of military instruction during a period of 28 days. He took a part in the great military manœuvres at Laon. From the first day of the month to the 10th he made, like his comrades, a daily march of 30 kilometers. On the 10th he felt an obtuse or dull pain over the left thigh and began to be unable to keep his place in the field. The military physician who examined him failed to recognise the affection. He was compelled to continue his march, and after four days he supported his trouble no longer and became unable to advance farther. Then he was sent to Paris where he arrived on the 21st, that is 11 days after the beginning of the disease. His regular physician examined him and said that he (the patient) had a double coxo-femoral arthritis. Is it possible that a simple arthritis could have made its appearance suddenly over both hip-joints and in ten days, according to the statement of the patient, disappear almost without the production of pain? Is this not a matter of reflexes? If our brother physician had not been taken up with his numerous occupations, on closely examining the patient he would have found, at least, that the case was a singular one.

The patient was in the hospital at Tenon, and was then brought here. I did not see the patient at first; he was sent by the resident physician, Dr. Dutil, to the ophthalmological ward where the inequality of the pupils and the Argyll Robinson sign were first noticed.

This association of a destructive arthropathia and the pupillary sign, induced me to suspect tabes. There are arguments in *pro* and *con;* however, the latter manifestations shows evidently that we have to deal with a tabetic arthropathia.

The patellar reflexes are normal, as you see; its abolition, so frequently met with in tabes, is not the absolute rule. Besides, you must not neglect to inquire into the urinary function. The patient tells us that from the beginning of the affection, he had been troubled with involuntary passages of urine at night, and always made efforts to prevent this disagreeable occurrence. This symptom may be included under the category of *false urination* of Professor Guyon. Finally, the patient suffered, after the trouble of the bladder, from pains in the feet and legs; these pains coming on and going away suddenly. We have, then, collected a sufficient number of symptoms—the Argill Robinson sign, paralysis of the bladder,

lancinating pains—with which to establish a correct diagnosis. Now, this man presents another phenomenon which belongs to the tabetic series also, having come on before the development of the arthropathia. The sign is that of the *tabetic mask*. This peculiar sign was shown to me by Duchenne. It consists in the partial loss of facial sensibility, and in the failure of the patient to properly recognize the situation of the face; he is only conscious of the existence of the posterior portion of the head. In addition, there is loss of taste and also anosmia or loss of the sense of smell. I have often described this symptom, so little known in general, but, nevertheless, very interesting. The history of *maschera tabetica* has been masterly described, as I have had occasion to teach you, by the lamented Miliotti in his remarkable work on tabes dorsalis.

Our patient has his mask, although imperfectly developed. The forehead conveys to him only an unpleasant sensation. These symptoms, as I told you before, preceded the development of the hip trouble.

Before entering into the examination of these arthropathies, let me remind you of a case, analogous to this one, which you will find in the first Vol. of my *Tuesday Lessons* : A man, 40 years of age came to me suffering from an arthropathy of the right thigh. The articulation was, without any prodromic symptoms, suddenly affected while the man was at his work. I was surprised at the rapidity of the onset, and, at the same time, at the slowness of the arthritis which likewise had produced a complete luxation of the joint. The history was similar to that one of the present case. We found the same normal condition of the patellar reflexes, paralysis of the bladder and the same crisis of the lancinating pains.

I have endeavored to show you how we can study these deformities of the thigh by the employment of certain methods. I have for a long time advised the study of the *naked* by the physicians. We must confess that we do not know exactly the proportions and shape of the body, hence when we examine a naked patient we believe that we are able to notice this peculiar deformity at once. We should always begin with this method of examination.

You know that in the language of art by the word *canon* is meant the relations which the proportions of the various parts of the body bear to one another, one of these parts being termed the *module* and taken as the unit. We have thus the *canon* of the Egyptians, the length of the waist being considered as the *module* or unit; that of the Greeks, based upon the length of the palm of the hand ; and then, the ones proposed by Jean Goujon, Leonardo da Vinci, etc. The *canon* of modern times recognizes as the module the height of the head, (22 centimeters as the average) 7 or 8 times of which constitutes the total height of the body.

Mr. Paul Richer, in his investigations on morphological anatomy has proposed an *electric canon* which embraces the advantage of the anthropological *canon* of Topinard and the advantage of that of the artists. The *module* which he uses as a unit of measurement is the height of the head, 7½ times of which makes up the height of the body. The trunk will measure four lengths of the head from the vertex to the gluteal folds ; the inferior extremities will also measure four lengths from the plant of the foot to the anus.

Let us now apply these measurements to the proper interpretations of the present clinical case. This man has lost 5 centimeters of his height since he first began to feel sick. What has been the cause of this? In a healthy man the bi-trochanter line passes along the smaller portion of the anus, and the plane along the superior iliac spine ; the measurement above the first line gives 5 centimeters. In this case the bi-trochanter line is nearer the iliac spine, so as to be confounded with it, and it shows the loss of the 5 centimeters referred to.

Over the back, in a healthy man, the bi-trochanter line passes along the inferior extremity of the sacrum ; in our patient it passes 5 centimeters above the sacrum. The trochanters have been raised, while the iliac bones have decended as a result of the coxo-femoral lesions. We find, at the same time, a transverse dislocation of the trochanters, where an apparent enlargement of the pelvis and the attenuation of the median gluteal fold, place the anus, so to speak, in an exposed condition. The inferior gluteal fold is also diminished.

I will next call your attention, in a few words, to the anatomical lesions that we see after the clinical manifestations we have so far studied. You can judge for yourselves in examining the specimens that

we have collected and placed in our Museum. The tabetic arthropathies are characteristic and their study cannot be separated from that of fractures of the same nature, since we have to deal in both cases with a similar pathological process. There are certain bone lesions which may be called preparatory, and which consist in softening, the results being an extreme brittle condition of the hard substance at the point of lesion. In such instances, the slightest traumatism, a simple effort, may produce what is called a spontaneous fracture. If the fracture does not occur in the continuity of the bone similar alterations on the level of the epiphyses may also result in fracture of these. We must, however, make a distinction in the two instances. In the one case the fracture may be a *fragmentary* one, as in the head of the femur, of which I show you here this example. It is divided into two pieces, one of which remains in the cotyloid cavity. In the other case, there may be what is termed a *molecular* fracture, in which the epiphysis is simply crushed and appears as if it had passed through a grindstone. It is to these bones, with heads so deformed, that I have given the appellation of *drum-sticks* (*baguettes de tambour*). These serious lesions are produced without inflammatory processes and without the production of osteophytes.

Such constitute, at least, the type of simple cases. There are other varieties, and in these we find cases in which we come across vegetations more or less analogous to those of a dry arthritis; but the alterations I have pointed out are the ones which are more or less peculiar to tabetic arthropathies.

To resume: We have here a patient in whom, a month after the appearance of the affection, we were able to recognize tabes, although the condition was only manifest by the existence of arthropathia. Now, it is important to be able to recognise things, at the beginning, and in the present case an early diagnosis would not have been useless.

There are the benign and malignant types of the disease; the last ones are due to the fact that patients continue to walk. I verily believe that if our patient had been advised rest from the beginning, destruction of his articulations would have been avoided.—*Translated from La Semaine Medicale.*

INCOMPLETE LAPAROTOMY WITH INJURY TO THE BLADDER.

By WM. GOODELL, M. D.,
PROF. OF CLINICAL GYNÆCOLOGY, UNIVERSITY OF PENNSYLVANIA.

Gentlemen:—The woman now before you presents a very interesting case. She is 40 years of age, has been married 17 years and has never conceived. Her menstruation has, as a rule, been pretty free, but of late it has become profuse and excessively painful—more and more so every year, until now she suffers prolonged agony each monthly period. Her pain lasts some 48 hours and is so severe that her physician has often given two grains of morphine hypodermically in six hours time in order to allay it. Neither antipyrin nor chloral has any effect whatever upon this pain. She has become morbid over it and is all the time dreading her next monthly period. Further, between her monthlies, she has continuous pain in the right ovarian region, preventing her from working.

On further examining the patient in my office, I found a fibroid tumor in the interior wall of the womb—not a very large one, but sufficiently so to distend the uterine cavity and make the canal patulous. This accounts for the excessive menstruation. She was so nervous that I was not able to make a satisfactory examination; yet my conviction is that the womb and tumor are fixed by adhesions and that both appendages are probably diseased.

The cervical canal might be dilated and the tumor enucleated from its rest; but that is a very hazardous operation. Besides, it would not release the womb and the ovaries from their adhesions. We must, therefore, either remove the womb and tumor, or else the ovaries. If the ovaries are reachable and removable, oophorectomy will be the simplest operation to perform. By this means, the change of life will be brought about; the menstrual molimen will cease; the monthly flux of blood will be checked and the tumor will grow smaller and probably disappear in time. But sometimes the ovaries are wholly imbedded in the tumor and become part and parcel of it; sometimes they are stretched into narrow ribbons on the surface of the tumor and it is impossible to remove them. Then we are driven

to the more serious operation of removing womb, tumor, ovaries and all.

Strange as it may seem, it is much harder to remove a small tumor together with the womb, than a larger one. A sentimental and an enamored poet once wrote, "My wound is great because it is so small." His rival, to show the absurdity of the thought, wrote as a rejoinder: "Then 'twould be greater were it none at all." So you might rejoin: "If it be more difficult to remove a small tumor than a larger one, it should be still more difficult to remove no tumor at all." But while my paradoxical statement contains no rhyme, it contains good reason. For the upward growth of a large tumor tends to convert the cervix into a kind of pedicle; whereas a small uterine tumor generally compels the complete extirpation of the whole womb.

The incision is now being made between the two recti muscles, down to the fat lying above the peritoneum. Since in this case, the intestines lie between the tumor and the parietes, I must proceed carefully to cut layer by layer. Here we come directly upon the peritoneum. Ascitic fluid! Let us see what is the meaning of this. Now I am in a quandary, as to whether the opening I have made is into the peritoneal cavity or into a cyst. This looks like thickened peritoneum, and my fingers pass right down to the womb, but—there is a membrane separating it from my fingers. A small fibroid tumor is palpable in the wall of the womb. I suspect that I have made an incision into the bladder, although the fluid removed, did not have a urinous smell. To verify this, my son will pass the uterine sound into the bladder. I have cut into the bladder, for you can see the sound protruding through the abdominal incision. The bladder is adherent to the abdominal wall up to a point above the umbilicus. Hence I shall have to extend my abdominal incision to a point still higher up, where I can reach the abdominal cavity.

This is a very remarkable condition; and I must proceed with great care, as all landmarks are wanting. Separating the bladder from many omental adhesions and also from the abdominal wall, from above downwards, I find the womb and its appendages, the intestines and the bladder, matted together in an inextricable mass.

Is this opening in the bladder a serious accident? Not at all. The wound is but one inch in length and, from the adhesions to the abdominal wall, is wholly extra-peritoneal. I sew it up with a continuous suture of catgut, which extends through all its coats, and it will be included in the sutures of the abdominal wound. With catgut, I do not hesitate to pass through all the coats of the bladder, because this suture by swelling will effectually fill up the holes made by the needles. Had I used silk, I should have gone to, but not through the mucous membrane of the bladder.

I shall now break up some uterine adhesions, and release some of the adherent intestinal loops. But as for removing either of the appendages, I am afraid that cannot be done without irreparable mischief to the surrounding and adherent intestines. I, indeed, cannot feel the ovaries or tubes, much less define them, unless it be the left ovary, which seems as small as a bean, and lies behind several layers of false membrane, to which is glued an intestine.

The fact is, for the sake of the woman's life, I shall be obliged to stop all further procedures and close up the wound. Such a retreat from an operation, such a defeat, rarely happens, but it occasionally will happen, and I must confess that I always feel somewhat humiliated at its occurrence, for when one undertakes to do a thing, one does not like to fail in the doing of it.

What shall be said to this woman when she comes out of her ether? I shall tell her frankly wherein I failed, but I shall lay stress upon the adhesions which have been severed, so that the bane will have something of an antidote. Then I shall comfort her with the assurance that after the menopause, her sufferings will be lessened. Then again, this operation, abortive as it has been in so far as the extirpation of the appendages is concerned, may set up such trophic action as greatly to lessen the size of the womb and the number of adhesions. I have seen this happen twice in a most remarkable manner; in each case a large fibroid dwindled away, the fixed womb became movable, and adherent appendages apparently became free.

I shall put her upon the prolonged use of ammonium chloride and of corrosive sublimate by the mouth, which will di-

minish pelvic congestion. She will also be supplied with suppositories of watery extracts of opium for the pain of her monthly periods.

Should a drainage tube be used here? No! Everything has been done aseptically; the bleeding has ceased and no cavities containing pus or fluid have been opened, so that a tube is unnecessary. I am always glad when a drainage tube can be dispensed with, as it tends to cause hernia. Then, too, there is the danger that a silk ligature left in the abdominal cavity, may become septic, from the use of a drainage tube, and cause a sinus which may remain open indefinitely unless the ligature is removed. Only a few days ago, I assisted a physician in cutting down upon a ligature which had been thrown around the left appendage and had become septic and consequently a foreign body, on account of a drainage tube. The sinus had remained open for months and the lady menstruated through it, because it led directly to the left uterine cornu. It was removed, and in a week's time, the fistulous track will probably close up. The same thing has happened to me on more than one occasion. I have sometimes hooked out a silk ligature with a long hooked probe. This one could be caught, but not hooked out, as it was too firmly attached to the uterine tissue, so it had to be cut out. To avoid this mishap I now use catgut ligatures, which last long enough to do their duty, but not long enough to become a foreign body.

I now begin to close the abdominal wound, by deep sutures including the peritoneum and taking in a liberal amount of tissue. Care is taken to include the wound of the bladder in these sutures, so as to make it wholly extra-peritoneal, and prevent the possibility of any leakage of urine into the very vulnerable serous cavity. Iodoform powder is dusted over the abdomen and bichloride gauze, together with several thick layers of baked cotton complete the dressing. Iodoform is so repulsive to some patients, that I sometimes substitute boric acid for it.

It seems strange that no history of abdominal inflammation could be elicited in this case, for the woman must have had a severe attack of peritonitis. Probably it was an inflammation of the bowels, and was treated accordingly by her physician. Possibly it may be of specific origin—in which case it might have advanced insidiously, without much constitutional manifestation.

Note.—For three days after the operation, bloody urine escaped from the self-retaining catheter, which was kept in for a week. The patient's recovery was prompt.

EVIL EFFECTS OF CAUSTICS ON THE UTERUS.

Cittadini (*Bullet. de la Soc. Belge de Gynec. et d' Obstet.*, No. 5, 1891) states that a patient, aged 28, was treated in Paris for "hæmorrhagic endometritis." On December 31st, 1890, a stick of chloride of zinc was introduced into the uterine cavity. She was discharged on January 16th in good health; the sound could be passed with perfect ease. The period, due on January 30th, did not appear till February 8th, and the cervix suddenly became contracted. By the end of May the sound could not be passed more than 1½ inch; the stricture seemed to be situated at the os internum. The period continued regular, so that the stricture could not have been impermeable. In the summer of 1891 the patient consulted Dr. Jacobs, of Brussels. She had profuse purulent leucorrhœa, hypogastric and lumbar pains, and painful defecation, but micturition was not affected and the period not particularly painful. There was a tumor to the right of the cervix, and deposit in Douglas's pouch and to the left of the cervix. The sound could not be passed beyond the stricture. Dr. Jacobs's diagnosis was "right perimetritis and cystic salpingitis complicating purulent endometritis with uterine stenosis." Abdominal section was performed; the tumor proved to be a suppurating broad-ligament cyst; the tube was occluded at its abdominal end, and contained muco-pus, but was not dilated. The right ovary had undergone sclerocystic degeneration. There seemed to be total absence of the left tube and ovary. The patient recovered. Cittadini observes that whatever might be the precise relations of the stenosis to the disease of the appendages, it is certain that the cauterization caused the stenosis.—*Brit. Med. Jour.*

COMMUNICATIONS.

REFLEX HEADACHE.*

By F. H. EDSALL.
PITTSBURG, PA.

In presenting for your consideration the subject of reflex headache, I feel almost as though an apology were necessary for occupying your time with a subject apparently so time-worn and threadbare, yet so pregnant with interest for the general practitioner, as well as for the ophthalmologist, is the subject that I feel confident you will grant me your indulgence for having selected it as my paper this evening.

I am sure that if the physician in general practice could but go over the cases he is called upon to treat, he would find that his aid is more often sought for the relief of headache than for any one ill to which flesh is heir, and I am equally sure he will as often be "put to his trumps" in finding a means of accomplishing this relief as in any disorder of the human economy other than the one under consideration. This arises from an easily understood cause. Headache is such a commonly occurring symptom of many deep-seated and obscure affections that be he ever so skillful a diagnostician the physician is many a time and oft compelled to grope blindly in search of the cause, and in consequence his thrusts at the peace-destroying demon of headache must now and again be widely delivered. Remedies there are without number for headache; the doctor, the druggist as well, is never at a loss for a drug or prescription to relieve the throbs of pain which rack the sufferer's brain, but he who makes drugs his staff upon which to lean will find too often that he has but a broken reed for his support. It is not, I think a rash statement, nor one not warranted by statistics, that the majority of recurring, or of persistent headaches, are reflex in character due to some abnormality in the refractive state of the patient's eyes, or to an imperfectly maintained muscular balance between the sets of little muscles which regulate the motions of the eyes—the much talked about heterophorias of the present day, the muscular insufficiencies of the past, and this being the case, the most that can be hoped for from medical treatment is a temporary obtunding of the pain for which the sufferer seeks relief. The busy practitioner of general medicine is unable to spare the time to go into a prolonged examination of the refractive state of the patient's eyes; in fact it may not occur to him to do so or he may not have the means at hand to accomplish it were he able to spare the time. Naturally, therefore, his mind turns to the pharmacopœia for something with which to relieve his patient, and he has recourse to one or the other of the prescriptions he has found useful in similar cases. This may, if the case be not of reflex origin, end the matter, but if it be due to eye strain, it will prove of temporary benefit at best, and the patient returns so often to the doctor that the case becomes a bugbear, and at last, discouraged and despairing of being able to further aid him, the physician bethinks himself of his friend, the oculist, and to him the patient is forthwith dispatched. If it be eye-strain that has caused the suffering it is soon determined and quickly relieved.

Now, as to the character of headache due to eye-strain. What is there in the structure of the eyes that should cause them to give so much offence in so many of our fellowmen? And why is it that drugs have no power to relieve the aching brain where the eyes are at fault, or at best give but temporary relief. In answering the question may I beg your indulgence in advance if I trespass so far upon your good nature as to cite some points in the anatomy of the eye, which it is necessary for you to bear in mind in order to appreciate the causative action of the eyes it producing headache?

The eye proper, is, as you know, a spheroidal body, which may be compared to a miniature photographic camera, the retina representing the sensitive plate. The distance between the sensitive plate and the dioptric apparatus of the eye is a fixed distance; that is to say, the distance between the retina and the back of the crystalline lens is so related that when the eye is at rest and normal in structure, the focal point for light coming from a distant object will be exactly upon the surface of this sensitive plate, known as the retina. Suppose now, however that this relationship is destroyed through the retina being

*Read before the Alleghany County Medical Society, March 22d, 1892.

situated in advance of the point where it should be; that is to say, through the antero-posterior diameter of the eye being shorter than normal, as not infrequently happens. The refractive power, the ability of the optical system to focus the light, is an invariable power, thus then we have a condition in which the optical system is called upon to focus the image of the object observed upon a sensitive plate in advance of the point at which the system is adjusted to focus it. One or two things must then happen, either we must get but a blurred and indistinct image of what we look at or else the focusing power of the eye must be increased. The eyes have an inborn abhorrence for blurred images, and in a case like the one cited, unknown to their possessor, set about remedying the indistinctness of outline. By means of the mechanism with which the eyes are provided to enable them to see objects close at hand, the mechanism of accommodation, the refractive power of the lens of the eye can be increased by making it more convex. Now, in an abnormal eye, such as I have mentioned, this mechanism is brought into play. The need is for a stronger lens to make up for the diminished distance between lens and retina, and it is thus met. In doing this, however, the eyes part with a portion of their power of accommodation. It would be a work of supererogation for me to describe minutely the mechanism by which this ability to alter the focal adjustment of the eye is accomplished. I will merely recall to you what you already know, that the ciliary muscle, by contracting or relaxing increases or diminishes the convexity of the lens which is attached to it, thereby shortening or lengthening its focal distance. In normal eyes this mechanism is only called upon to enable the individual to see objects close at hand. In eyes that are too short this demand is constant and great in proportion to the amount of shortening. Now, in eyes of this character the eyes are constantly doing, as I have said, a certain amount of the work that normal eyes are only called upon to do at intervals, and if we have superadded upon this, the work necessitated in accommodation, there comes a time when the tired muscle begins to send out plainly-felt reminders of this overtaxed state. So nicely are the eyes adjusted to their work that for a long time they can accommodate for close work and make no complaint, if light and other conditions be favorable, but if the amount of work be exceeded for any considerable time, as in the case where in addition to the work of accommodating for near objects, they must cover up the blurring which would be caused by the shortening of the globe it will not be long before the demand for aid will be felt. It is not so much the continuous work which the eyes are called upon to do which makes the need for assistance felt; that is to say, it is not the work of compensation for the defect in structure, unless this be high in degree, for this would doubtless be unnoticed were it not for the additional demands which civilization makes upon the eyes in the way of close work that gives the fillip which causes the eye to break down, because the ciliary muscle is doing more work than it is capable of doing for any length of time.

In the normal eye there is rest from work when the eyes are fixed upon some distant object, for then the light falls upon the retina focused by the lens at its least convexity. In the shortened eye there is no rest except during sleep, for if the eye is to see clearly at any time the surface of the lens must be to a certain degree more convex than when the eye is normal, which means a demand upon the ciliary muscle. With the intimate nervous connection between the eye and the general nervous system it is not difficult to understand that the constant irritability thus necessitated should communicate itself to the more distant parts and produce the continuous pain which is noticeable in such cases. I have thus far mentioned only hypermetropia as a condition inducing reflex headache from eye-strain. As a matter of fact, any of the refractive errors are equally capable of producing this condition and astigmatism more often even than simple hypermetropia is the cause of cephalalgia. This condition is one in which the cornea, instead of being regularly curved throughout its entire extent is, in one meridian, in consequence of congenital defect, of disease, injury or from operation become differently curved from the other.

Thus, to roughly illustrate, it is as though a ridge traversed it from one side to the other. In consequence of this there is never any distinct retinal image so long as the defect remains uncorrected, for there being different focal distances for

the light coming through the different meridians of the cornea, there is no possibility of focusing both sets upon the same point. The effect of this is to keep the accommodative apparatus in a continuous struggle to bring both sets of rays to a focus, and from the constant struggle weariness soon ensues,—sooner, indeed, than in single hypermetropia, and the headaches follow. This condition may be of a variety of characters. There may be an hypermetropia in only one meridian, or there may be an all round hypermetropia with one meridian more hypermetropic than the other, or the eye may be near-sighted, myopic, in the corresponding way, or lastly, one meridian may be near-sighted, the other far-sighted. Myopia or near-sight may also cause headache, not through its action on the ciliary muscle, for in myopia there is less than the usual demand upon this in using the eyes. The eye is longer than it should be and the lens needs less convexity than it normally would. It is probable that the headache and other symptoms traceable to myopia are dependent upon the disturbance in the relationship which exists between convergence and accommodation. To look at an object close by the eyes have to converge in order to bring the image upon the yellow spot. Ordinarily this is associated with a considerable degree of accommodative action on the part of the ciliary muscle, however in a myope less use of the accommodation is necessary than normally to see objects close at hand, while there is still need for the same amount of convergence. It is this condition of disturbance which is doubtless responsible for headaches due to myopia. Still another abnormal condition of affairs in the eyes may cause reflex headache; this was formly known as muscular insufficiency. It is a lack of balance between the external and internal recti muscles. In converging to look at objects close at hand, there is a good deal of effort put forth by the internal recti muscles. If, as often happens, the internal recti muscles chance to be weaker than normal, the extra effort required to overcome the antagonistic pair of muscles soon causes fatigue, which very quickly produces nervous disturbance.

Having briefly called your attention to the conditions of the eyes which cause headache, I beg leave to consider the signs by which we should be lead to suspect the existence of eye defect.

If the patient complains of increased headache whenever his eyes are used for reading, or if the headache only appears after such use of the eyes; and if the headaches are localized about the temporal or frontal regions, the eyes should be looked to for an explanation, particularly if vision is faulty. So, too, if eyes become reddened easily, or the patient shows a disposition to grow sleepy over his reading, be his book never so interesting. Careful examination of the eyes with proper appliances will generally clear up the diagnosis.

As to treatment, there are but a few words necessary. Correction of the refractive error by proper glasses will usually give marked and quick relief. This correction should be done under a mydriatic, as without this, much of the defect will doubtless be over-looked. Protean nervous symptoms will ofttimes disappear like magic after proper glasses are adjusted, and the sufferer experience a relief before unknown.

If muscular insufficiency exist, this should be corrected by prisms, or by operation, and some attention to the general health is also demanded, as not rarely this is also at fault, and plenty of open air exercise is to be commended. I regret that the short time that has been given me in which to prepare this paper has prevented my making it more thorough and more interesting, but if I have succeeded in pointing out to you the road to relief for any sufferer who may be in your charge, and for whom medicine offers little hope of relief, I shall feel that it has amply repaid me for the work of writing it.—(*For discussion, see Society Reports*).

FRACTURE OF THE NASAL SEPTUM.

Dr. W. J. Clegg has observed two cases of this injury during the past year, in both of which the cartilage of the septum was displaced so as to occlude the left nostril. In the first case, by making four cross-cuts through the cartilage eight triangles were formed, and these were separately fractured at their base. The septum could then be pushed into place and the nostril plugged to support it. At the end of three weeks the result was perfect. *Lancet*, Jan. 2, 1892.

PNEUMONITIS AND ITS TREATMENT.

By A. D. Binkerd, M. D.,
WEST MONTEREY, PA.

While I do not wish to recite the particular treatment of any particular case of pneumonitis coming under my care in a long series of years, it may not be without interest to review the general method by which very satisfactory results have been obtained by me in the treatment of all forms of this very common and too fatal affection. I say too fatal, because readily amenable to proper and judicious treatment when timely applied.

Experience has taught me that many things besides the administering of drugs may be advantageously done for the prompt relief of the patient, and that he who depends wholly upon the effects of drugs in extreme cases is doomed to disappointment.

While it is well to understand therapeutics and the theoretic effects of certain remedies upon the nervous, respiratory and circulatory systems, it is better to know that theory is sometimes diametrically opposed to the facts in actual practice, and still better to dare to deviate from theory when the results justify.

I am called to see a young man who after several days of exhausting fatigue and exposure to inclement weather had a severe chill, loss of appetite, a slight headache, general malaise continuing all afternoon of the day before. After the chill passed off fever began to rise, the breath grew short with acute pain at each inspiration. Breath grew constantly shorter, and the pain more distressing. Exacerbation of fever and delirium was a prominent feature during the night.

On examination I find the temperature 103° to 105° F. Pulse 120 to 140 per minute. Respiration 26 to 30, with suppressed hitch, or a marked tendency to hold the breath at a certain point. On percussion I find marked dullness at the lower portion and exaggerated resonance of the apex of the right or of the left lung as the case may be. Ausculation reveals a peculiar dry pneumonic murmur at this stage of the attack that words cannot describe so well as the trained ear can recognize. All of which possess a pathognomonic value in the diagnosis. Secretion of the kidneys is scant and high colored, the tongue is furred, dry, whitish red and hot; mouth clammy and teeth rapidly accumulating sordes. A hacking cough, dry and resonant, fails to bring up the characteristic brick-dust sputa.

We have here a case of acute congestion and inflammation of the lung—involving only one or both lungs as the case may be. A pneumonitis—liable to become complicated with pleuritic effusion and in time, pulmonary hepatization, uræmic poisoning and death. Three days ago the patient was in vigorous health, full of blood, happiness and hope. His florid complexion and bounding pulse still testify to these facts.

I must act promptly but judiciously. What must first be done? From the median basilic or median cephalic on the affected side I take a full stream of dark blood to the extent of 10, 12 or 16 oz. till the pulse becomes soft and compressible and the patient expresses relief from the acute pain at each inspiration. The skin has grown moist, and venous and arterial tensions have become relaxed. The patient expresses himself as feeling decidedly comfortable and soon goes quietly to sleep.

Look out now for a new danger. But let me say here, "Never try this method of treatment upon a patient of the African race, nor upon an aged patient whose supply of vital fluid is already too scant, nor in a case in which the disease has already passed beyond the first stage. Should you so far forget yourself as not to heed this timely warning, you will surely regret your experiment of reviving the "lost art" of phlebotomy.

Now while my patient has been sleeping a soothing and invigorating sleep for full fifteen minutes, I have prepared in the most scientific manner, as taught to me by the Elder Gross himself, America's greatest surgeon, a thick heavy poultice from linseed meal, thoroughly stirred up with boiling water to the consistency of hasty pudding. This is now spread evenly, a foot square or more, on the double of a piece of cotton cloth a yard wide and nearly as long. The third part is now folded over the plastic mass, over which four to six drachms of tr. opii. camph. is evenly poured. The whole is now held before the fire until it is quite warm. In this state it is applied to the bare skin of

the patient, from the vertebral column behind, around the affected side to a point beyond the sternum. A dry binder is now neatly pinned around the whole and that part of the work is finished. The effect is stimulating to the heart, soothing to the nervous system and decidedly antiphlogistic. In six hours the poultice is renewed and so continued for several days gradually diminishing the thickness or depth of the mass according to requirements of the case. Be exceedingly cautious in renewing and finally removing the poultice that secondary inflammatory symptoms do not supervene. This topical application I have found in my practice of 25 years to be of the utmost importance, and one that never failed me, in its beneficial results.

Is this all that is indicated in this case, since the patient is so comfortable and quiet and the active inflammation probably subdued? By no means. Hence I warned you to look for danger. To win a battle is a glorious triumph, but to utilize the victory calls into requisition the highest type of generalship. To bring your patient out of this prostrate condition by gradual advances, without the occurrence of violent exacerbations of any feature inimical to convalescence, will test your generalship in utilizing a victory and and establish your ability to restore a patient to perfect health by judicious, rather than theoretical medication. What further shall be done in this case?

Scrutinize closely the symptoms. Cardiac sedatives may be necessary. These are readily found in the salts of bromine. Cardiac stimulants and cardiac tonics are indispensable. As to the former, we give the preference to digitalis, in spite of its toxic effect upon the cardiac muscle. Here, theoretic medication is superseded by practical application to particular cases. Why should we seek a result through an agent which theoretically poisons the very organ we wish to stimulate to greater strength? For this we care but little so long as the theory does no practical injury to our patient. Hence, theory must oft stand aside to give preference to the demonstrably practical and useful.

As a safe cardiac tonic we regard the carbonate of ammonium as indispensable in all cases of pneumonitis, especially after full bleeding. Of this we give grs. ij to iij every three or four hours in a f℥ of mistura glycerrhizæ comp. (Brown Mixture of the *U. S. Pharmacopœa*,) or,

℞ Syr. pruni Virginiana .....f℥iij.
" Scillæ omp .....
" Senegæ..... ..... āā f ℥ss.

To this add ammonium bicarb ℥j. Dose a teaspoonful every 3, 4 or 5 hours.

This is a very convenient and eligible form in which to exhibit a cardiac stimulant, to which we attach great importance in the treatment of all cases of pneumonia. The condition of the bowels and secretions generally as well as judicious attention to the proper nourishment of the patient are also of the utmost importance.

Of this class of patients treated on the above described method we have not had the misfortune to lose one case in a score of years.

Young children of whom I have treated many, both after measles and of the common prevailing type of congestion and inflammation of one or both lungs, recover almost invariably under the above treatment modified to suit the nature of the case.

I have never resorted to phlebotomy in the child. The disease generally yields promptly to free application of iodine followed by a poultice topically. Cardiac sedatives or depressants such as tincture aconite root, (Norwood's tincture) combined with syr. pruni Virginiana. Cardiac stimulants and tonics, Foxglove and ammonium according to the nature of the case. Attention to the bowels and secretions is also of the utmost importance.

There is one more class of cases to which the above treatment in general is not wholly applicable. I have had apparently the most hopeless cases in persons over seventy years old recover after long weeks of patient care and treatment from a severe attack of pneumonitis.

When called to see a case well advanced in years, suffering from the symptoms of acute congestion and inflammation of the lungs, such as—fever; rapid, small, wiry pulse; short breath, pain at each inspiration with a sense of increasing stricture around the chest, it behooves us to scan every feature of the case most critically. Upon our wisdom and promptness of action depend the life of the patient. This patient is well advanced in years. His masticatory and digestive apparatus are defective, consequently he is not well nourished. His blood is deficient in quantity and defective in quality. His is

evidently not a case for the lancet, or general bloodletting. But we can apply a cut cup over the seat of the pain, one ounce of blood may be safely taken and with marked benefit to the patient as we have repeatedly proven. Several dry cups are now set over and around the painful portion of the chest. The abstraction of blood and serum from the deeper structures have a marked and soothing effect upon the symptoms of congestion and inflammation. A warm poultice with a full Dover's powder have procured rest and sleep for the patient. The recurrence of pain is effectually controlled by vigorous application of the dry cups upon the back front and sides and renewal of the linseed meal poultice. The application of the tincture of iodine full strength has also a salutary effect. The exhibition of the fluid extract of ergot in 5 doses twice or thrice daily may check or prevent serous effusion of the inflamed tissue. Twenty drops of muriated tincture of iron with two or three grains of quinine in a wineglass of water, twice or thrice daily, soon as it can be well borne is perhaps equally efficacious in preventing effusion and toning up the system.

The syrup of wild cherry with nitre and tr. opii. camph. in teaspoonful doses every two or three hours, combined with the carbonate of ammonium, have a special potency in suppressing cough and facilitating expectoration.

In this class of cases we proceed best with the expectant plan of treatment. All of which means, *watch your patient most carefully*, that you may take advantage of the earliest symptom of change of what ever character, check and control the same by sedative, depressant, stimulant or tonic as the symptoms may indicate.

We have long been in the habit of giving, once or twice daily, one or two or more grs. of quinine sulph. to all these cases whom we could persuade to take the drug. But since I have obtained equally good results in children, to whom the sulphate of quinine could not be administered on account of its bitter taste, I have sometimes questioned whether its exhibition is at all essential to successful treatment. I do not, however as yet feel justified in dispensing with this drug in these cases, until unmistakable proof of positive injury be presented.

Finally, my experience has taught me that pneumonia as generally met with in this part of the country, is promptly amenable to treatment in the very young and on through life to the very aged, and that favorable results bear some relation to the early recognition of the symptoms of the attack, and the promptness with which the symptoms are combated.

In short, the general results depend largely on what the attending physician and the nurse in their combined wisdom and experience tend to make them.

CEPHALHÆMATOMA, WITH REPORT OF A CASE.*

By O. W. WILSON, B. S., M. D.,
LAWRENCE, KANSAS.

The case I am about to report fell into my hands by accident; it is out of my line at present. My practice for two and a half years has been confined to the Indians and employes of Haskell Institute and a few families of friends outside. During this time I have not had a case of obstetrics, and my practice among very young children has been virtually nil.

My desire in reporting this case is to call the attention of this society to one of the most important, and as yet but rarely recognized diseases of very early childhood. Dr. Kelly, of Baltimore, says: "Few men outside of the rank of pure specialists are aware that such a disease as cephalhæmatoma exists." Cases which occur in the practice of the general practitioner are diagnosed and treated by him upon "general principles."

The literature upon the subject is very meagre. In several works upon obstetrics the subject was scarcely mentioned and in none that I consulted was I able to find a satisfactory description of the disease, and if, as Bouchacourt says, the disease occurs once in 250 newly born children, the subject is certainly an important one; for a man with a moderate obstetrical experience will be likely to have one or more cases, the treatment of which demands decision as to their nature and the course to be pursued.

Cephalhæmatoma is a circumscribed blood tumor lying between the periosteum

* Read before the Eastern Kansas Medical Society and Golden Belt Medical Society—joint meeting, Topeka, Kan., April 7, 1892.

and one of the flat cranial bones, usually appearing from a few hours to a few days after birth, gradually increasing in size until it forms a tense round or ovoid swelling.

The commonest seat of these tumors is over one or both parietal bones, but owing to the fact that the periosteum is more firmly united at the sutures the tumor never crosses a suture, but is confined to a single bone. We may have double or even multiple cephalhæmatoma.

The skin over the tumor remains normal in appearance, is painless except as in my case continued pressure caused restlessness; we have no pulsation, no perceptible decrease on pressure nor increase in size when the child cries, differentiated in these respects from meningocele.

In a few days generally—but in my case, weeks—there appears a hard bony rim around the tumor one to two millimeters in height, which gradually becomes more prominent, the tumor receding through this craterous like opening simulating somewhat a depressed fracture of the skull.

The disease is much more common in males than in females, according to Bouchard in the proportion of 34:9. Why of greater frequency among boys? I have seen no explanation.

As to exciting causes there is a difference of opinion; some think it due to intra-uterine causes, while others think it due to injury—however slight—inflicted during birth. The fact is it may occur, as in the case here reported, in natural easy labors where no forceps are used.

Valleix and Paul Dubois have shown that in the newly born the external table of the skull is porous, vascular, incomplete and partially absent.

The diploic vessels therefore are almost exposed, and it is easy to understand how a trifling pressure applied to the yielding head of an infant during delivery may cause the pericranium to glide upon the subjacent bone and by a slight injury to the vascular connections produce a hæmorrhage. The diagnostic points are time of appearance, tendency to increase in size, circumscribed and lateral, non-pulsating, painless and non-reducible.

The prognosis is generally favorable.

The treatment advocated is the let-alone-treatment, the tendency being for the tumor to be gradually absorbed and disappear spontaneously. Where suppuration takes place, incise, thoroughly evacuate and treat antiseptically.

The above I have gathered from different articles upon the subject from which we would infer the diagnosis to be plain, prognosis I have said favorable and treatment dogmatic. How fully all these indications were apparent in my case will be shortly seen.

Mrs. W., multiperæ, mother of four children, all healthy, confined October 7th, 1891, labor was of short duration and as she expressed it the easiest time she ever had.

The physician was called early but scarcely got there before labor was completed. Child male, average size and seems perfectly healthy. The physician came once or twice after and found mother and child doing so well he did not deem it necessary to prolong his visits.

I was called in about the fifth day. The child up to that time had not had a natural operation from its bowels, medicine had been given several times, followed by injections. I was called to correct this bowel trouble. The mother had plenty of milk, she said, but the child was very poorly nourished. Its little legs and arms were very much wasted. It was plain to see that its food was not being assimilated.

I prescribed one-thirtieth grain of calomel every two hours and this not having the desired effect, I increased to one-twentieth grain which after one or two doses, produced quite a free operation from the bowels.

I found it necessary to keep up this treatment giving one tenth grain calomel daily to get its bowels to operate at all.

About the sixth day erysipelas appeared on the right hip, which in a few days had extended involving the thigh, leg and foot respectively, fading from above, as it progressed down the limb. When the disease had about disappeared from the right limb, it next appeared in the penis and scrotum which became very much swollen and very angry in appearance. From here the erysipelas extended down the left limb, thence into the arms, hands and face and small patches on the trunk. This trouble I treated by keeping the affected parts wrapped in absorbent cotton and smeared with oxide of zinc ointment. The scalp was not attacked by the erysipelas.

We made a persistent and stubborn fight against this dread disease, at one time the little one being almost enveloped in cotton and smeared all over with the ointment.

The erysipelas had all disappeared in about four weeks with the exception of resultant abscesses on top of the right foot and middle toe and back of left hand, all of which when ripe were opened, thoroughly cleansed and drained.

Up to the time of the appearance of the erysipelas no tumor had been noticed; this might have been due to the fact that the cephalhæmatoma was developed on the occipital bone and it would not be noticed as quickly there as on the side of the head. About the ninth day was the first time my attention was called to a swelling on the back of the head. The tumor was then as large as a good sized hickory nut, ovoid in shape, quite soft and as I thought somewhat reducible; situated on the occipital bone almost immediately over the posterior fontanelle. I expressed my fears to the family that it might be a meningocele and gave a grave prognosis.

My plan of treatment was to keep a large wad of absorbent cotton over the tumor, held in place by means of a tight fitting cap; this I thought would distribute the pressure and prevent irritation of the skin over the swelling.

As time went on, I saw the case every day. I examined carefully for the bony rim but could not make out any. About Nov. 20, five weeks after the tumor was first discovered, I could make out quite distinctly the bony rim. The tumor was now as large as a hen's egg, tense but painless and no signs of inflammation. I determined now if it did not begin to subside in a few days to aspirate and apply pressure.

On Nov. 25th I was called in haste, the tumor had broken they said but the child was still alive. I went immediately, found the baby sleeping quietly; the tumor had ruptured, saturating the cotton. The character of the discharge was pus mixed with blood. I washed it out thoroughly, applied carbolated cosmoline on cotton and bandaged. In a few days the opening had entirely closed, no signs of the tumor save the elevated bony ridge which gradually closed, which smoothed down and in ten days presented a perfectly normal appearance. The child now is in good condition, bowels regular, is well nourished, has grown fat and with the exception of a little undersize is as healthy looking a child as there is in the family. Surely the little fellow has earned the right to live, and has shown the world that a new born infant can make a good fight against disease.

ÆTIOLOGY, WITH SUGGESTIONS AS TO TREATMENT, OF ACUTE (SPASMODIC?) OBSTRUCTION OF THE STRICTURED MALE URETHRA.

By W. M. L. COPLIN, M. D.
PHILADELPHIA.

ADJ. PROFESSOR OF HYGIENE AND DEMONSTRATOR OF PATHOLOGY, IN THE JEFFERSON MEDICAL COLLEGE; ADJ. PROFESSOR OF PATHOLOGY, IN PHILADELPHIA POLYCLINIC; A. A. SURGEON, MARINE HOSPITAL SERVICE; PATHOLOGIST TO ST. AGNES HOSPITAL ETC., ETC.

For the most part the teaching with regard to acute or spasmodic urethral stricture is, in my opinion, incorrect. As is well known, the almost universal opinion is that the condition depends upon a spasm of urethral circular muscular fibres, which, superadded to an already diminished lumen, causes its entire occlusion. In the writer's opinion, a far more lucid explanation is to be found in applying our knowledge of inflammatory processes in other mucous membranes. To briefly summarize this we recall that there are three distinct stages in an inflammation of a mucous membrane :—1st, hyperæmia or a determination of blood in the submucous capillaries, during which period the membrane is dry and beginning swelling is evident; 2nd, exudation into the submucous areolar tissue of the nutrient inflammatory products, thus giving rise to more swelling and a beginning relief of the submucous tension by intercellular transudation and epithelial desquamation producing rapidly the third stage of free mucous flow, during which the submucous areolar tissues are relieved of their serum and the swelling subsides.

No one can deny that the above briefly outlined facts apply to the mucous membranes of the nose and upper air passages. Why not to the urethra? It will not be infrequently observed that while the so-

called "spasmodic" stricture is active, a similar "spasmodic" condition may be observed in other mucous membranes. The next time you have a so-called spasmodic stricture to deal with, please inquire into the other points, and nine times out of ten, you will find that the mucous membrane of the nose is also swollen as manifested by the "stopped up" head with which we are all more or less familiar. If we stop to think we will see the very apparent reasons for this. All cases of spasmodic stricture of the urethra develop from causes which give rise to congestion or hyperæmia of other mucous membranes, viz:—exposure to cold, intemperance, or, we may have hyperæmia, indeed, a perfectly developed catarrhal process in the urethra, following sexual excesses and in this as is well known spasmodic stricture, so-called, not uncommonly manifests itself. The occlusion of the urethral calibre occurs during the first two stages of the acute inflammatory process, and hence is transitory in respect to time, giving rise to the idea usually associated with spasm. In support of the idea advanced in this article, there are certain therapeutic points of great value. Thus, in the medical treatment of spasmodic stricture, empiricism has demonstrated that those remedies which favor an active cutaneous circulation, (thus indirectly depleting the mucous membranes by abstracting blood from the engorged submucous vascular supply and favoring lymphatic return of the inflammatory transudation) without a single exception are beneficial in the so called spasmodic stricture. In other words, treat the inflammation, acute in character, exactly as we treat similiar conditions affecting for example, the nasal or bronchial mucous surfaces. Secure hyperactivity of the superficial circulation, by hot baths, hot fomentations opium and belladonna, or their alkaloids, and other remedies having similiar physiological actions. Check, if possible, the determination of blood to the mucous membranes exactly as you would in impending laryngitis or acute coryza, in neither of which you would use a bougie, nor should you in the urethra unless the symptoms be urgent and the dysuria demand immediate relief. This, of course, may, in many cases, be positively indicated.

Turning to the surgical treatment or rather instrumentation, does it not bear out the assertions herein made? When passing the bougie or catheter *all* admit that when the obstruction is reached the greatest care must be used. Why? We are told that the spasm will be thus overcome. Is it not equally likely that the pressure slowly displaces the œdema and thus renders the track patulous? If a bougie be introduced and immediately withdrawn, the urine flows freely, is spasm so easily overcome, and does it not recur more rapidly? The œdema returns slowly and if the patient be past the second stage of the inflammatory process, it does not return at all. The same is true if, after instrumentation, the patient be put to bed and medical treatment, as already advised, be fully carried out. Again, we are all too well acquainted with the little effort demanded in this class of cases in order to induce a false passage. Does spasm offer any adequate solution for this? If spasm be added to an already fibroid wall, is it likely to prove a macerating agent? Certainly not. Œdema explains this peculiarity fully; as the swollen and softened membrane pits and pockets with the greatest ease and thus facilities puncture upon the slightest use of force, and when once punctured the very swelling continues obscuring the normal passage and renders re-entrance a practical impossibility, the opening once made, remaining open, just as a trocar puncture in anasarca, which is naught but general œdema. There are other reasons for considering this condition one of acute swelling rather than spasm, but space forbids more detailed review. No reference has been made to the extremely small quantity of muscular fibre in the urethral wall, nor to the fact that sufficient inflammation to induce a stricture must alter the contractibility of the little present. Lastly, it is freely admitted that dysuria due to acute inflammation of the prostate, is caused by the swelling of that organ and not to any imaginary spastic condition. I cannot for a moment assume that there is present anywhere in the urethra sufficient involuntary muscular tissue to offer serious resistance to the urinary flow, while to my mind, a mucous swelling, which, in the glottis is absolutely obstructing under the the most violent efforts of the powerful muscular apparatus of respiration, may afford ample cause for obstruction to the egress of the normal contents of the urinary bladder through an already narrowed urethra.

SOCIETY REPORTS.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Scientific Meeting, March 22, 1892.

Dr. F. H. Edsall read the paper announced for the evening, entitled:

REFLEX HEADACHE. (SEE P. 727.)

Dr. Davis: Taking the subject of reflex headache as a whole, the paper touched on but a very slight cause of reflex headaches, compared to the many other reflex headaches. Indeed, I am not certain if you eliminate neuralgia and organic troubles, such as tumors and the like that produce pain in the head, if there is any headache that is not reflex. We know the stomach when disordered will produce headache, and many different organs in the body will produce headache; possibly many of the headaches we can not trace to the exact organs which are affected are reflex. No doubt, the eye in its impaired refraction causes many headaches. On the other hand there are many defects of the eye, even those mentioned in the paper tonight, which will not cause headache, if the general system is in perfect order. I recall very distinctly a case that came under my observation. A patient of mine suffered very considerably with headache. I believed the liver was the source of these headaches along with the fact that she resided in a malarial country. The patient visited a neighboring city, was taken with the headache, was sent to an oculist, who found what is present in almost every eye, a slight degree of astigmatism; indeed, it is an exception for an eye not to be astigmatic, but this in the course of nature, in a healthy body, can be accommodated, so that it really produces no trouble until the system is out of order in some other way; hence in the case I speak of, they went to an oculist who found there was some astigmatism, put on a glass which thoroughly overcame this, but the headaches persisted. The patient returned and came under my care, and was put under treatment to relieve the liver and the bad digestion, and she never put the glasses on again until another attack of the liver would occur. There was marked astigmatism, but it would not cause the headache. The natural mechanism was perfectly able to overcome it until the system was out of order in other ways. And so it is in many of the forms of refraction of the eye, not only when the general health is impaired, but as you advance in age, as you grow older and can not overcome it, it will give rise to difficulties which you never knew you had. If we would just simply stop at the thought of reflex headaches and stop at the eye, I claim we would stop at a very small proportion of the headaches that are caused from reflex action, and many of the so-called headaches from eye strain are also caused by a disordered system, that if corrected, the eye strain itself would not amount to as much as sometimes we are wont to find in that respect. I would call attention to the fact that it has also been my misfortune to meet with a number of reflex headaches that were caused by the glasses the patients wore, sometimes a perfectly fitted glass. In a very short time the patient, getting rid of whatever trouble existed, finds that the glasses which were fitted at first are entirely too strong, with the old accustomed power of accommodation, and really finds these glasses producing headaches. In quite a number of cases I have had patients remove glasses which at one time fitted them very nicely, and after being removed their headaches were benefited. Of course, this is not to be blamed on the oculist, but certainly there is a necessity for the patient going frequently to see that the glasses are perfectly adjusted, and not depend on the fact that he went once and had them fitted.

Dr. Grube: I am one of those who believe the oculist finds defects in a great many eyes, and I am also one of those who believe the defects are there. It is but a part of our life that we have defective eyes. The defects are there, and are to be met and recognized, and these defects cause headaches in a great many more cases than we have any idea. We sometimes fail to remember that we are only a link of a long chain of man's history and forget that man's eye like the eye of the lower animals, is built for long range. Man used his eyes for long range for many years, and it is only in the last few generations, since the introduction of printing, that man has taken short range for his eyes. We find our eyes are not built for that purpose. A child is sent to school, and if hypermetropia is not there already it is soon developed by the close work, and I think an investi-

gation would show a large percentage of these eye defects to be in school children, showing the necessity of their being corrected, and I would never undertake to treat a case of chronic headache until I had that element eliminated, until I had the patient examined by an oculist, and that part corrected. We have other reflex headaches besides these. We have others which are not reflex, and when the physician has fitted glasses on his patient and dismisses him he has not done his whole duty. One other great element of these headaches, while it is not exactly reflex, is generally blamable on our civilized life, and that is the defective elimination of the uric acid. The great amount of meat diet, of nitrogenous food, must be eliminated from our system, and when the kidneys fail to eliminate this we have the troublesome headaches, which are so very persistent, and which will persist as long as we have the nitrogenized food there.

Dr Allyn: In regard to the correction of the eye for the relief of headaches, we all recognize, of course, that we have a high degree of hypermetropia, or astigmatism. When a person gets to be 20 or 25 years of age, daily accommodations make glasses necessary. Many times that degree of hypermetropia, or astigmatism, may be in the eye of a patient without producing the headache of which we are speaking tonight. There is another fault in which our work is employed. It is in the correction of low errors in the hypermetropia, especially such errors as the optician ordinarily overlooks. If you will notice a paper published in the journals recently you will see that there is an array of cases of headaches where there is the slightest degree of astigmatism. There is one point I might add, that even if the glasses are found unnecessary after the health has been restored, there is yet a field for their employment. If a person has a headache without the glasses every week, but with the glasses, once in two or three weeks, their use is valuable as far as any other remedy. A glass that may not fit perfectly, may not restore perfectly, but oftentimes has its use as a remedy.

Dr. Edsall: In reply to Dr. Davis' first point, I beg to state that I had originally intended to make the paper wider than it proved to be, but I found it getting beyond me in point of time which I had to complete it, and although I had hoped to touch on the other headaches, which I am perfectly well aware exist, I found it would be impossible for me to do so and make the paper at all worth reading. I had good authority for stating that there are but few causes of headaches in children at least. The authority to which I refer is Dr. Seguin's article in Keating's Encyclopedia of Diseases of Children.

In that, if my memory serves me right, he states specifically that there are but two causes of headaches in children, one is eye strain and the other presbyopia. As to Dr. Davis' point in regard to the universality of astigmatism, this is well taken, and I will state that but few cases are on record in which the eyes were not to a degree at least astigmatic. The degree of astigmatism which causes trouble varies very much in different patients. In one patient it will cause a great deal of trouble, while in another patient it will be overlooked for a long time. I have been surprised to find the amount of astigmatism in existence, and work comparatively comfortably carried on. I have a case under my care at the present time, and the patient for years has been able to carry on all the duties of life, and has suffered comparatively little until the age when the hardening of the lens made the astigmatism uncomfortably apparent. Presbyopia always brings out defects of this character, and hypermetropia as well, and if the defect is not felt early in life, it will be felt after presbyopia intervenes.

As to glasses causing headaches, here again I agree with Dr. Davis. These glasses prescribed under mydriatics, in all existing defects of the eye do, for a time almost invariably when first put on cause discomfort to the patient. There are also some patients who are able to adapt themselves with little or no trouble, but if the glasses are not put on until after this effect has disappeared, the difficulty of accommodating them is felt much more severely than it would be otherwise, and this difficulty is sometimes so very apparent as to cause headache in itself; but if the patient persists he will find that this factor in causing headaches will shortly disappear. Dr. Allyn brought up some very interesting points. The low grades of astigmatism sometimes cause more suffering than higher degrees do, largely, because, as Dr. Allyn says, they are overlooked. Higher degrees produce so much discomfort that

resource is soon had to the ophthalmologist for relief, but the low grades, unless careful examination is made, are overlooked time and time again, and the patient suffers without relief until by chance he falls into the hands of some one who recognizes it, and the defect is corrected. Dr. Chisholm, of Baltimore, before the American Medical Association, said that all cases of astigmatism should be corrected. In some cases in my experience, astigmatism will cause no discomfort for at least some time, but in other cases it causes considerable discomfort. It is no quick or easy matter to correct these defects even when time and patience are both unlimited. I am well aware that eye strain is not the only cause of reflex headaches, but I still stand by the assertion that it is the most common cause.

SELECTED FORMULÆ.

ANTI-EMETIC IN INFANTILE GASTRO-INTESTINAL CATARRH.

Tincture musk.....20 drops.
Red wine.....15 grms.
Syrup.....15 "
Infusion salep.....60 "
Sig. Small teaspoonful every two hours.

—N. MANDESTAMM, *La Semaine Médicale.*

ANTISEPTIC SALVE.

The following (*Lo Sperimentale.* No. 18, 1891) is well recommended as an antiseptic salve:

℞ Zinc oxydat.....decigrms. 3.
Zinc chlorat.....grams. 1.5.
Gelatin..... " 20.
Aquæ..... " 30.

METRORRHAGIA.

The following formula is spoken highly of in metrorrhagia:

℞ Ergotin pur.....5 j
Aq. fontan. dist.,
Aq. menth. pip.....āā f3 ij¼.
Syr. cinnamon.....f3 v.
Sig. One to two tablespoonfuls every hour.

—*Gaceta Medica Catalana*, 12, 1890.

TYMPANITES ACCOMPANYING METRITIS AND PERITONITIS.

The following formula is recommended:

℞ Naphthol,
Magnes. carbonat.,
Carb. vegetabil.....āā 5 j
Essent. menth. piperit.....gtt. x.
Sufficient for fifteen powders.
Sig.—A powder to be taken whenever the distention becomes distressing.

—*El Siglo Medico*, p..606, 1890.

ACID DYSPEPSIA.

The following (*Med. Record*) often affords relief in cases of persistent sour stomach:

℞ Sodii salicyl.....5 j
Spt. vini gall.....3 ij.
Solve et adde,
Syr. aurant. cort.....3 j.
Vini albi fort.....3 iij.
M. One tablespoonful before meals.

FOR ODONTALGIA DUE TO ACUTE PULPITIS.

When toothache is dependent upon acute inflammation of the dental pulp, the distressing symptoms to which the condition gives rise may be relieved by introducing a bit of cotton impregnated with one of the following solutions into the cavity of the carious tooth or teeth, after thorough cleansing:

℞ Menthol.....gr. xxxvj.
Chloroform.....f3 j. M.

℞ Cocaine hydrochlorate } āā gr. iv.
Morphine hydrochlorate }
Creasote, sufficient to make a paste of creamy consistence.

℞ Morphine sulphate.....gr. iij.
Atropine sulphate.....gr. jss.
Distilled water.....f3 j M.

—*L'Abeille Mèd.*

TREATMENT OF SCABIES.

Kaposi recommends the following plan of treatment, which has been successfully carried out for ten years in Vienna Clinic, in about five hundred patients each year:

℞ Florum sulph.,
Ol. fagi.....āā 20.0
Sap. vir.,
Axung. porci.....āā 40.0
Cret. alb. pulv.....5.0
M. Sig. Apply once without previous bath and wrap patient in woollen blanket.

In private practice the patient can put on a suit of tight-fitting wollen underwear and go about. Wool has the advantage over linen that it does not soak up the ointment, but leaves it in contact with the body. A bath is to be taken only after the skin has begun to peel. A bath before the ointment makes the skin unnecessarily liable to irritation.—*Deutsche Medizinische Zeitung.*

ACUTE VAGINAL CATARRH.

The following injection is used in acute vaginal catarrh:

℞ Zinci sulph.....5 jiss.
Aq. fontan. dist.....f 3 xiij.
Sig. Sufficient for one injection.

—*Revista Clinica e Terapeutica*, 12, 1890.

THE

MEDICAL and SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.
(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:
29 to 35 North Tenth Street, Cor. Filbert.
EDITORIAL OFFICE:
Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates)....$1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt **"The Medical and Surgical Reporter"** and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

☞Please accompany orders with the money, and address all communications to

LEADING ARTICLES.

THE TREATMENT OF ENDOMETRITIS.

The treatment of endometritis, at the present time, appears to be going through one of the reactionary stages so common in therapeutics. When Bennett's pathology concerning uterine, especially cervical, inflammation was accepted, and when knowledge of pelvic inflammation was in its infancy, it was the custom to attack endometritis with caustics—potassa cum calce, chloride of zinc, nitric acid, etc.—for the cure both of supposed endometritis and metritis. Later, under the lead of Emmet, the existence of inflammation of the endometrium was denied, the conditions usually classed under that name regarded as due to venous congestion produced by inflammation of the periuterine tissues, or by tumors or certain conditions of remote organs. Under this theory the conditions of the uterus were purely secondary, and were to be improved by the use of treatment directed against the causative factor. According to Emmet this was usually cellulitis. The theory of Emmet did not gain universal acceptance, but it profoundly modified the methods of treatment employed in his country.

The propriety of making intrauterine applications came to be questioned on the ground that the uterine condition was secondary and not the primary disease. Moreover, it was found that intrauterine applications were not without danger—in certain cases peritonitis and even death resulting from them. Experience showed that peritonitis was induced, usually, in cases in which it had previously existed, or when the uterine syringe was used in cases in which the cervical canal was narrow—in these cases uterine colic resulted immediately, at times to be followed by peritonitis. It was found also that frequently intrauterine treatment did

not effect a cure, and that it was always painful and tedious.

Likewise the followers of Hodge held that in cases in which uterine displacement exists, the displacement is the disease and the intrauterine condition but a symptom which will disappear when the displacement is corrected.

The foregoing facts together with the wide acceptance of the theories of Hodge led many practitioners to abandon intrauterine applications. Prominent among them is Goodell, who voices a very general opinion when he says that his results have been better since he gave up the old methods. Those who have abandoned intrauterine applications restrict local applications to the vagina and the canal of the cervix, and pay due regard to the general health. Intractable cases and those inducing hæmorrhages are treated by dilatations and curetting under anæsthesia — care being taken to operate only on uncomplicated cases of endometritis. The recognition of the fact that a large proportion of the cases of endometritis are complicated by salpingo-oophoritis, peritonitis, and pelvic tumors is most important. This was insisted upon by Noble in a paper entitled Minor Uterine Surgery, read before the Philada. Obstetrical Society (*Annals of Gynæcology and Pædiatrics*, Jan. 1891.,) as being the greatest advance made in the subject, from the standpoint of therapeutics. This fact explains the want of success frequently met with in the past, and also many of the accidents following intrauterine treatment.

Apparently the subject of endometritis has reached a satisfactory state. It was recognized as a primary and as a secondary condition—as due to puerperal sepsis, gonorrhœa, and less-defined conditions; as due to uterine and other pelvic tumors; as due to, or at least kept up by, chronic inflammation of the uterine appendages; and as due to certain displacements of the uterus. Recently, no new facts in its pathology have been discovered, but the more general recognition of the relation between endometritis and salpingitis—the former preceding and inducing the latter—caused a reaction in favor of intrauterine treatment, on the ground that if the endometritis can be cured promptly that the salpingitis can be prevented. This reaction can result only in good, provided the teachings of the past are not forgotten. Careful diagnosis is imperative, and only cases of uncomplicated endometritis must be selected for intrauterine treatment. This is the key to success, and it cannot be too strongly emphasized.

The tendency at present is to favor the use of the sharp curette after dilatation under anæsthesia, with full asepsis. This is to be followed by packing the uterus with iodoform gauze, and by applications of Churchill's tincture of iodine or of carbolic acid until a cure is effected. This plan of treatment appears to be a sound one for the following reasons: The use of an anæsthetic permits—first, a more thorough examination and a more accurate diagnosis, with the exclusion of all but complicated cases which guards against "setting up peritonitis" so common in the past; second, a more thorough cleansing of the parts with soap and water, and a more thorough use of antisepsis, which minimizes and practically removes all danger; third, a more efficient use of the dilator and curette, thus enabling the removal of more of the diseased tissue. The uterine canal being dilated first by the dilator and then by gauze, applications can be made to the endometrium thoroughly and with little pain. In this way the duration of treatment can be much shortened, and the chances of extension of the inflammation to the tubes minimized.

A danger to guard against in cases of uncomplicated endometritis, is that this reaction in favor of dilatation and curetting under anæsthesia and with full anti-

sepsis, with applications made later to the endometrium through the crevical canal, may induce venturesome men to use the dilator or curette or intrauterine treatment with the applicator or uterine syringe without anæsthesia and without antisepsis, and in cases of endometritis complicated by tubal inflammation. If unhappily this should be the case the poor success and the disasters of the past will be repeated.

THE VALUE OF MASSAGE HISTOLOGICALLY DEMONSTRATED.

The favorable results from the use of massage are too well-known to need repetition. True, the method has its limitations, and a disregard of these has led to some unsatisfactory experiences, but when judiciously employed it has been used on almost every part of the body with most satisfactory results.

Undoubtedly the greatest value of massage is in the treatment of sprains, luxations and juxta-articular fractures. It has been generally conceded that the beneficial results from massage in these conditions have been due to a stimulation of the circulation and absorption, but its exact action had not been demonstrated until Dr. Castex reported the results of a series of careful experiments to the Society of Biology of Paris, at a recent meeting.

The question Castex sought to answer was as to what scientific explanation could be offered for the results obtained by massage. Castex proceeded to produce a variety of traumatisms upon large dogs, such as sprains, contusions, luxations, etc. The injuries were always made symmetrically—that is similar injuries on two corresponding parts. The one part to be massaged and the other treated otherwise. Both the immediate and ultimate obvious results were carefully studied; and finally, the muscles, both massaged and not massaged were carefully examined microscopically. The nerves and blood-vessels in the region of the traumatism were also examined. The entire course of the experiments extended over a year.

The immediate results of massage were a lessening of pain and a diminution of swelling. The later results were chiefly an absence of ultimate atrophy of the parts. The dislocated shoulder of a dog which had been massaged, ultimately measured 30 centimetres in circumference, while the opposite shoulder which had been similarly injured but not massaged, measured only 28 centimetres.

The histological examinations of the parts yielded most interesting results. The muscles of the traumatized region on the side that had not been massaged showed: first, a dissociation of the muscular fibres, well marked by longitudinal striæ; second, a hyperplasia of the neighboring connective tissue; third, a slight enlargement of the muscular fibres; fourth, the sarcolemma was usually found intact. On the contrary, the muscles of the traumatized region of the side that was massaged were entirely normal. The vessels on the non-massaged side showed evidences of a hyperplasia of their outer walls, and the nerve branches near the injury were irritated and gave evidences of perineuritis and endoneuritis. On the side massaged both arteries and nerves were normal. These results were found to be constant.

Dr. Castex's experiments are of sufficient importance to awaken the interest of every practitioner, especially those who have made use of massage with unsatisfactory results; and they certainly deserve supplementing and extension by other investigators.

A NEW ANTIPYRIN REACTION.

L. van Itallié states, in the *Apotheker Zeitung*, that when nitric acid is added to a solution of antipyrin, and the mixture heated, it will in a little while turn cherry-red. The intensity of the reaction depends upon the amount of antipyrin in the solution, and upon the quantity of acid used.—*Ex.*

BOOK REVIEWS.

LECTURES ON SURGICAL PATHOLOGY: Delivered before the College of Physicians of Philadelphia, 1891–1892. By Roswell Park, A. M., M. D., Professor of Surgery, Medical Department, University of Buffalo; Surgeon to the Buffalo General Hospital; Fellow of the German Congress of Surgeons, etc. Reprinted from the *Annals of Surgery*, Vols. XIII, XIV and XV. St. Louis: J. H. Chambers & Co, 1892.

These lectures upon selected topics in the domain of surgical pathology constitute the Mütter Lectures of 1890–1891, delivered before the College of Physicians of Philadelphia. They may deservedly be called one of the most complete reviews of the subjects treated by contemporary authorities, and fully evince the scholarly attainments of the author. They embrace the facts obtainable from all modern methods of research, and these are presented and elaborated in a manner which gives to the reader a clear, comprehensive idea of the value of the knowledge we already possess, as well as indicating the lines which may be hopefully pursued in future work. Perhaps the most salient point in these lectures is the demonstration by innumerable facts of the absolute necessity of the young surgeon of to-day, who hopes to excel in his profession, to acquaint himself thoroughly with the technique of the modern methods of investigating pathological processes, and to have special proficiency in experimental physiology and pathology, pathological histology, bacteriology and general pathological facts. Perhaps the greatest good that will be accomplished by these thoughtful and well-prepared discourses, will be the stimulus to increased labor in these studies which they are calculated to inspire.

The introductory lecture dwells upon the importance of surgical pathology, and cites the life-work of several eminent surgeons as examples of the necessity of this factor towards success. It then presents the subject of inflammation in accordance with the latest views concerning its rational classification into varieties; following this comes an interesting account of the formation of ptomaines and toxines by bacteria, as well as a definition and classification of them. A notable feature in this chapter is a table showing the variation of hæmoglobin in health and different diseased states. In the second lecture the constitution and formation of pus is ably dealt with, and the name "prophylactic membrane" is suggested for "pyogenic membrane." In this lecture Dr. Park refers to the possible value of the examination of the blood in septic states as a means of diagnosis, and quotes the experience of Eiselsberg, who has reported four cases in which pyogenic cocci were discovered in the blood prior to the occurrence of septicæmia.

The third lecture is a most important one because it deals with "pyogenic organisms," which are divided into "the obligate" and "the facultative." In this lecture the author has gathered the gist of modern research in this direction and presents the subject in a clear and forcible manner. Both sides of vexed questions are freely discussed, although he does not hesitate to advance his personal views when they seem called for. A valuable addition to this lecture is the appended bibliographical index.

The fourth lecture is devoted to the consideration of "The Results of the Absorption of the Products of Wound Infection." The conditions formerly grouped popularly under the terms "blood-poisoning," Park divides into five forms, as follows: I. Surgical fever. II. Intestinal toxæmia. III. Sapræmia. IV. Septicæmia. V. Pyæmia. This lecture is very interesting and well worthy of careful reading, and especially commendable is the restriction of the term sapræmia to toxæmia resulting from infection from a local source *outside* the tissues of the body proper.

The fifth lecture discusses peritonitis, and the tests applicable to antiseptic substances. It contains some admirable suggestions regarding these important subjects which space will not permit us to refer to at length. The method by which an antiseptic should be properly tested is given as practised in the Hygienic Institute in Berlin. It is really the mode insisted upon by Koch.

In the following lecture Park takes up the subject of tetany and tetanus, and gives us the best thought of the day concerning their causes, nature and symptomatology. The review of the various theories concerning the ætiology of these affections is good reading, and is followed by the proof of the specific microörganic causation of tetanus.

The remaining lectures consider in de-

tail many of the diseases in which bacilli have been proven to be present ætiologically. The remarks on tuberculosis are exceedingly interesting, and should be read attentively by every surgeon.

It is impossible to notice at length the many commendable points in Dr. Park's lectures. They are modern, practical, well written, and embrace the best that has been discovered concerning the affections discussed. We can recommend these lectures as a concise and successful endeavor to present a really modern *résumé* of the advances in the field of surgical pathology.

LITERARY NOTES.

—"*The Philadelphia Polyclinic*" is the title of a new quarterly devoted to practical scientific medicine, and is published by the Philadelphia Polyclinic. The subscription price is $1 a year. Each number contains 60 pages. The contents are made up of lectures, clinical notes, favorite prescriptions and book notices. The articles are very good; the same may be said of the typographical appearance.

—The most recent addition to medical periodicals is a monthly entitled *Food*. Each number contains about 60 pages. The subscription price is $2 a year. The present number includes articles by Dr. J. Madison Taylor, Dr. G. M. Hammond, Katherine Armstrong, Ward McAllister, M. E. W. Sherwood and Florence Morse. The journal contains much matter of general interest to the laity, and is illustrated.

—P. Blakiston & Co. announce that they will shortly publish a work on Materia Medica by Dr. Wm. Hale White of Guy's Hospital It will be printed in one compact, handy volume. The American copyright edition will be edited by Prof. Wilcox of the N. Y. Post Graduate School. Dr. White does not do inferior work, so that we are assured that the promised book will be one of value.

PERISCOPE.

THERAPEUTICS.

RECENT DRUGS IN MEDICAL PRACTICE.

Dr. Barclay, of Banff, the President of the Aberdeen Medical Society, in an address on the "Recent Drugs in Medical Practice," said,—Dealing first with hypnotics, he found the bromides useless, but of benefit when combined with the tincture of hyoscyamus, in infantile convulsions, menorrhagia, epilepsy. Ten to fifteen grains each of bromide of potash and antipyrin were especially beneficial in epilepsy. Chloral hydrate, if continued for any time, required to be used in dangerously large doses; amylene hydrate, sometimes induced sleep, but was uncertain in its action, and the same result occurred in the use of urethan. Paraldehyde, he found satisfactory, but chloralamide not infrequently induced delirium and disturbed sleep.

Sulfonal had proved the most successful of the hypnotic group without any unpleasant effects, and was especially beneficial in cases of delirium tremens and asthma. Passing next to antipyretics and analgesics he had found gelsemium useless. Antipyrin acted both as an analgesic and an antithermic, but was liable to be followed by great depression, and on this account, he deprecated the existing freedom of its sale by druggists, without the prescription of a medical man. Antifebrin was a valuable antipyretic, but of little use as an analgesic.

Both as a febrifuge, and as an analgesic, Dr. Barclay had found phenacetine most useful, and he adduced several striking examples of its value. The addition of quinine enhanced its effect, and this combination, he eulogized in the treatment of acute rheumatism and herpes zoster. Exalgine has acted well as an analgesic but required careful handling.

The president next spoke of saccharin, oxalic acid and salol. He said saccharin and salol in 5 grain doses and oxalic acid in one-half grain doses, had been successful in the treatment of chronic cystitis. Salicylate of ammonia had proved of value in cases of Bright's disease, by causing the disappearance of albumen from the urine. In phthisis, creosote was not read-

ily borne, but the oil of eucalyptus gave good results, and in the night sweats, he had found the administration of agaric acid and agaricine, very serviceable.

Ichthyol and aristol in ointment did well in the treatment of psoriasis.—*British Medical Journal.*

ETHER AS A STIMULANT AT THE TEMPERANCE HOSPITAL.

A correspondent of a contemporary expresses surprise that at a public meeting at the Temperance Hospital it was announced that the internal use of ether is allowed in the hospital in place of alcohol. We cannot think that there is much to justify this difference. Ether drinking is a vice which has but lately in Ireland assumed grave proportions, requiring special legislation. It is affectation to regard the use of such an agent as morally or physically better than the use of approved forms of alcohol. By all means let the physicians of the Temperance Hospital cure disease—where they can do so equally quickly—without alcohol. Such treatment is instructive, but where some form of diffusible stimulant is needed, to prefer ether to alcohol is scarcely the way to promote temperance. —*Lancet.*

THE ACTION OF ERGOT AND ERGOTINE

Wertheimer and Magnin (*Archives de Physiologie*, 1892, No. 1) publish the results of their investigations upon the action of ergot. They find by intravenous injection of ergotine a notable fall in blood-pressure, preceded and followed by an increase. The simultaneous diminution in the size of the kidney indicates that the fall in pressure cannot be attributed to a vaso-dilatation of the abdominal organs. The direct examination of ventricular pressure shows that it results from an enfeeblement of the cardiac contractions. Following hypodermatic injection, ergotine raises blood-pressure without a preceding depression. When injected into the blood, ergotine produces marked contractions of the stomach; in subcutaneous injection, its action upon this organ is still manifest, but less energetic. A preparation known as ergotinine, given by intravenous injection, raises blood-pressure and slows the heart. In moderate doses, it has no effect upon the viscera.

TUBERCULIN IN THE TREATMENT OF LEPROSY.

Kalindero and Babes (*Revue de Médecine*, 1891, No. 10, p. 817) have reported the employment of tuberculin in the treatment of eleven cases of various forms of leprosy. They found that the general reaction set in about twenty-four hours after the injection. Sometimes a second and a third reaction followed on successive days. Rapid repetition of the injections was followed by cumulative action. In some cases of tuberculous leprosy, small doses were followed by intense and protracted reactions. Local reaction was slight or wanting; exceptionally, it was intense and extensive; it manifested itself by injection of the infiltrated areas and the slow formation of crusts, with desiccation; the general condition was improved, though weakness resulted.—*News.*

THE THERAPEUTIC VALUE OF HÆMOGLOBIN.

In many cases of anæmia where ferruginous preparations are contra-indicated, P. Castellino (*Rev. Clin.*) prescribes hæmoglobin. The following are his conclusions from its use in 15 cases:—

1. The absorption of hæmoglobin is uniformly rapid.

2. It is well tolerated, even by patients having digestive troubles; and never gives rise to symptoms of intolerence, such as vomiting, meteorism, constipation, epigastric oppression, gastralgia, pyrosis, etc.

3. Its favorable actions on the blood is manifested by an increase in the number of the red blood-globules, their resistance, their specific gravity, and their color, their form and diameter soon approaches the normal.

4. Under the influence of hæmoglobin, the general condition of the patient improves, as shown by the return of the appetite, the regulation of the menses, more energetic nutrition, increase of body-weight increased dynamometric force, the favorable influence on the secretion of urea, and the disappearance of various subjective

phenomena of anæmia (erethism dysphagia, gastralgia, palpitation).

5. If the hæmoglobin is not continued until the patient is well, its action is only transitory and soon disappears.

6. In cases of secondary anæmia (carcinoma, tuberculosis, leukæmia, etc.), hæmoglobin is of little or no use, or, at most, the effects are but transient.

7. A daily dose of 0.20 gramme (3 grains) of hæmoglobin is sufficient to obtain a perfect cure.

8. Hæmoglobin is distinguished from other ferruginous preparations by the rapidity of its action, when anæmia is unaccompanied by digestive troubles and when there are no phenomena of intolerance, the latter gives as favorable results as hæmoglobin.

9. Hæmoglobin is pre-eminently indicated in cases of anæmia with serious digestive disturbance, and in the convalescence of fevers and maladies of long duration.—*L'Union Médicale*, December 22, 1891, p. 896.

JAMBUL IN DIABETES MELLITUS.

Dr. H. Hildebrandt, in the *Berliner klinische Wochenschrift*, 1892, No. 1, S. 5, contributes a paper upon the method of action of their now well-known remedy. He believes that it is upon the vegetable diastase and also upon the sugar-forming ferments of the blood-serum, saliva, and pancreatic extract ; an analogous influence upon trypsin and pepsin has not been determined. In diabetes, then, it is useful, because it diminishes the change of starch into sugar in the alimentary canal, and in the tissues the change into sugar of glycogen.

Dr. George Foy, in the *Medical Press*, 1892, No. 2749, p. 29, goes over the botany and pharmacology of the drug. After a careful analysis of the literature he concludes that the record is very fluctuating—marked success attained for very unpromising-looking cases by some physicians, and with the most carefully selected cases and perfectly pure samples of the drug others have failed to get any benefit from it. That the drug has an influence on the conversion of starch into sugar is shown by the experiments of Lascelles Scott, T. A. E. Balfour, and G. Sims Woodhead.

TREATMENT OF SHOCK

Chauvel recommends the following treatment of shock, acording to *La Médecine Hypodermique* for January, 1892: For the purpose of re-establishing the circulation, the patient is put in an absolutely horizontal position and massaged. He is also given alcoholic frictions and subcutaneous injections of ether. For the purpose of maintaining the bodily temperature, the air of the room is well heated, and the patient is surrounded by hot bottles, or placed in a bath of the temperature of 105° or 110°.

Internally, Chauvel administers alcoholic stimulants, such as rum or brandy, in the dose of from 1 to 2 ounces. He does not employ sinapisms or other inconvenient measures. When reaction has been obtained the stimulants are combined with opium for the production o eep. Chauvel mentions the intravenous injection of ammonia, as has been used by Penfold and Tibbis. In cases where shock is prolonged, strychnine, digitalis, and belladonna are to be employed, and electricity may be of great service.

THE PHYSIOLOGICAL EFFECTS OF THE FRANKLINIC CURRENT.

Damian, of Paris, has recently published a study upon the above subject.

By means of his experiments he has conclusively demonstrated, that under positive electrization the heart's action is stimulated, and contracts with greater energy, as indicated by sphygmographic tracings. The temperature, with the same insulation, and with sparks, was increased from .025 to.4 of a degree; while with the simple bath, positive insulation there was an increase in the temperature of .5 of a degree.

The production of urea under the influence of the electro-positive bath was sensibly increased, its weight being elevated from 24.64 to 26.3 grammes. The same insulation with sparks increased the daily total of urea from 27 to 28, 30, 31 and 32.68 grammes. The electro-negative bath was followed by an increase in the volume of urine. In no other form of application was the volume sensibly increased or diminished, while under the same insulation with sparks the amount of

urea was progressively diminished; but less with bath. The phosphoric acid in the urine was decreased under the negative electrization, but more so with the positive insulation.

The alkaline phosphates were diminished in the same proportion, but more so with with positive than with negative; less with bath than with spark. The earthy phosphates were decreased under negative, less under positive electrization.

Thus we see by M. Damian's experiments that the heart's action is stimulated, the circulation improved, the temperature augmented, and the excretions increased. Further than this he has not yet demonstrated; but he believes that there are effects which are as yet undemonstrable. A moral or psychic effect is universally conceded; but the above experiments have clearly proven that the influence of static electricity does not end there, as many are disposed to claim.

METHYLENE BLUE IN NEURALGIA AND MALARIA.

According to the *Berliner klin. Wochens.*, No. 39, Drs. Guttman and Ehrlich have found a decided effect from methylene blue in malaria. Ten centigrammes of the chemically pure drug are given in capsule five times daily. Dr. Immerwhar states, in the *Duetsche Med. Wochens.*, October 8, 1891, that under certain circumstances this same drug, given three times daily in dose of from two to five grains, gives relief in neuralgia, muscular rheumatism, and the nerve-pain of herpes zoster, but not in sciatica. Further trial in both neuralgias and malarious fevers must be made before the true value of the drug is known.

BROMIDE OF POTASSIUM IN CERTAIN SYPHILITIC AFFECTIONS.

Dr. Augagneur, (*Deutsche Med. Zeit.*, Jan. 7, 1892.,) has found that in certain syphilitics, especially women, there often appears about the sixth or seventh month of the disease a dyspnœa which may have come on suddenly or only after a gradual onset of some eight or nine days which may lead to almost complete aphonia. It is not alway a permanent but at times an intermittent aphonia, and for this reason the author concludes that the erythema of the mucous membrane of the larynx, which is usually the only thing found on laryngoscopic examination, can not be the sole cause of the alteration in the voice. In the belief that it is due more to a disturbance of innervation, bromide of potassium has been successfully employed in conjunction with iodide of potassium, as follows :

℞ Potass. Iod .....10. 0 grammes.
Potass. Brom.....20. 0 "
Syr. Aurant, Cort. .....100. 0 "
Aquæ Dest.....200. 0 "
S. A tablespoonful twice daily.

ACTION OF THE BROMIDES.

Féré, before the Société de Biologie at its meeting on September 17, 1891, expressed his belief that the results obtained by using bromide of strontium, instead of bromide of potassium, in treating epilepsy, are equally good, particularly after the potassium salt has been taken for some time, although the same doses are employed as of the potassium salt.

In regard to the assertion that persons taking the bromides rarely become tuberculous, Féré finds from experiments on guinea-pigs and rabbits that the administration of these compounds to animals who were inoculated with tuberculosis distinctly increased the progress towards a fatal issue.—*Revue Thèrapeutique Mèdico-Chirurgicale*, November 1, 1891.

THE ACCUMULATION OF BROMIDE OF POTASH IN THE DIFFERENT TISSUES.

Féré and Herbert, of Paris, have recently made some interesting experiments on this point and transmitted their report to the Société de Biologie. An epileptic, aged 64, began December 18, 1890, with 5 grammes daily of potassium bromide, then took six grammes daily, and, beginning October 13, 1891, 7 grammes daily until October 20, 1891. On October 23d he died with pneumonia. The various issues of the body were then carefully examined and found to contain, per 100 grammes, the following quantities of the salt: brain, 0.073; lungs, 0.082; liver, 0.104; spleen, 0.133; kidneys, 0.10; pancreas, 0.043; muscle, 0.062; cartilage, 0.041; bone, 0.087.

A PRACTICAL SUBSTITUTE FOR COD LIVER OIL.

Dr. G. H. Pierce, M. D., writes in the *New England Medical Monthly:*—Since 1889 *Linseed Oil in Emulsion* has been in constant use in my practice. I had found great difficulty in getting many of my patients to take cod liver oil in any form, and when linseed oil in a platable form was brought to my notice, it required but a few trials to establish its merits.

The preparation known as Linonine is a perfected emulsion, and superior to the Mistura Ol. Lini as first presented to the profession.

The writer was probably one of the first physicians in Danbury to make extensive use of the linseed oil emulsion, and did so alone on the merits of the preparation.

Cod liver oil is of course invaluable if the stomach will tolerate it, but there are so many complaints from eructations that it has to be abandoned, often when the system positively demands an oil food. Linonine is borne by a weak stomach, and any after-taste which may arise is only that of the flavoring matter, which is not at all objectionable. The oil is so finely divided in the process of emulsification, and the other ingredients so thoroughly mixed that nothing except a pleasant taste is noticed.

Linonine is indicated in all cases where cod liver would otherwise be used, and in some cases where the latter would not be. We would not think of prescribing cod liver oil in acute bronchitis; linonine, the linseed oil emulsion, is most useful in this affection, for combining the anodynes and sedatives, morphia and choral, where pain and inflammatory conditions exist, a perfect remedy is produced. No severer test of the worth of a pulmonary medicament could be found than those presented by the various forms and stages of La Grippe. During the great outbreak of this disease in the winter of 1889-90 I prescribed linseed oil emulsion with and without chloral and morphia, according to the degree of acute inflammation and amount of coughing, and obtained the very best results from its use. The very tight feeling in the bronchial tubes is moistened and loosened in the very first stages of bronchitis, and in the last stages the secretions are favorable modified.

Formerly, linseed oil was used only as a laxative, or cure for piles, or applied externally in cases of burns. The hindrance to internal use was owing to its disagreeable taste, which has been most beautifully overcome. Linonine it must be remembered is more than a simple oil—it is a compound pharmaceutical product—consisting, in addition to the oil, of hypophosphite of iron, oil of eucalyptus, oil of gaultheria, Irish moss, marshmallow, glycerine and dilute hydrocyanic acid.

In a case which I have at present, of annoying reflex cough, there being a tendency to vomit at each paroxysm of coughing, which has necessarily left the stomach in a delicately receptive condition, I prescribed linonine, and the patient at once remarked on the platableness of the preparation. Now, it wa san oil emulsion, and was not disagreeable to a delicate stomach.

How few, with such a combination of stomach and cough, could tolerate a cod liver oil emulsion at such a time. In ninety-nine cases, out of a hundred the returning taste of the fish oil would set the patient against it. Not so with the linseed oil. There is no taste to return to disgust the palate, and the oil is so thoroughly emulsified, and of so tempting a flavor, that the patient anticipates the next dose with a relish. Indeed, it is more difficult to keep one from "downing" the entire contents of the bottle, than to get him to consent to take in moderation the prescribed dose. The Doctor is receiving daily, literature and samples "useful in the treatment of LaGrippe;" the field is a prolific one, and every remedy is the best. From my experience with linonine, combining as it does nutritive, alterative and sedative properties, I am satisfied that its efficiency will not be long in being universally proven.

NITROGLYCERIN IN THE TREATMENT OF REYNAUD'S DISEASE.

Cates (*University Medical Magazine*, vol. iv. No. 5, 1892) reports a case of Reynaud's disease—that is, symmetrical gangrene of the extremities—in which great relief was obtained by the injections of nitroglycerin, commencing with $\frac{1}{100}$ of a grain, and gradually increasing the dose up to $\frac{1}{30}$ of a grain, three times a day. The patient grew better, sores healed, and pain disappeared like magic, so that the routine duties of life were again made possible.

THE EFFECTS OF SULFONAL UPON THE CIRCULATION.

The conclusions arrived at by Dr. Sgobbo Francisco, of Naples (*Annali de Neorologi*, Fas. II, 1891), are:

1. That sulfonal is a good hypnotic.

2. That given in doses of 3 grammes it exerts an influence upon the heart and blood vessels, reinforcing the systole aud increasing the vascular tone. This action upon the blood vessels is not continuous, for after a certain time there is a dilatation, and a progressive loss of elasticity, beginning first in the vessels of the brain, then extending to the periphery.

MEDICINE.

MOTOR PATHS OF THE SPINAL CORD.

Rossolimo (*Arch. de Neurologie*, Nos. 64 and 65, 1891) has published a long series of experiments upon hemisection of the spinal cord, the cord often being hemisected on opposite sides at different levels and at different intervals of time. The author considers that the most important result he has made out is that when in an animal submitted to hemisection of the spinal cord the voluntary movements of the paralyzed extremity come back to their primitive state, this is always brought about by the supplementing of the nervous paths cut by the operation by other paths running on the opposite side of the spinal cord and intact in it throughout the whole of their length from above to below; that is to say, from the crossing of the fibres in the pyramids of the bulb down to the level of the motor roots containing the nervous fibres for the posterior extremity, where they pass immediately from the side of the lesion.—*Brit. Med. Jour.*

A CASE OF SYMMETRICAL GANGRENE OF THE FEET.

Mr. W. H. Brown reports the following case: The patient had always enjoyed good health up to ten weeks prior to admission to hospital, when he was seized with violent and persistent diarrhœa, accompanied with abdominal cramps and surface lividity. This was followed by collapse, which continued for two or three days, during which time he complained very much of pain in both feet. His body lost its livid hue, but the skin over the anterior half of both feet remained discolored and cold. It was necessary to administer full doses of opium to control the pain. At the end of six weeks a line of demarcation formed and the pain lessened. On admission the granulating surface at the junction of the living and dead tissue was of an unusually brilliant pink color, and the discharge offensive. The heart sounds were normal and vessels healthy (both anterior and posterior tibials could be felt at the ankle); the temperature each night was 100° to 101° F., falling each morning to 98° or 99°. The process of separation was very slow. Three months after entrance, the discharge having become sweet and the temperature normal, the right foot was amputated, the ordinary incision for Syme's operation being used. The bones of the tarsus were found to be softened and infiltrated with pus, the cancellous tissue being replaced by soft cheesy material. The stump healed rapidly. The left foot was removed in similar manner, and also resulted in a firm stump. The patient was discharged four weeks after the second amputation. In ordinary senile gangrene, waiting till the parts have separated, or amputation far above the seat of disease, has been, and is, the method followed by the majority of surgeons. In the present case, when the gangrene was in every respect save one like an ordinary case of senile gangrene, the parts were removed, neither waiting for separation nor amputating above the disease. The result justifies the procedure, as the patient was saved many weeks of waiting, and only suffered the loss of those parts already destroyed by disease.—*Lancet.*

TUBERCULOSIS AND ERYSIPELAS.

Dr. J. Morton, of Mussoorie, describes some experiments in which he has been successful in curing animals charged with the tubercle bacillus by inoculations with the tubercle of erysipelas (Fehleisen's). Extended observation may yet be found to prove that in the erysipelas bacillus or its products we have the cure for tuberculosis. These experiments are the result of six months' labor, and augur a hope, even after the failure of Koch's treatment, that in his trail other observers may yet make a discovery.—*The Indian Medical Record*, October, 1891.

GONORRHŒAL RASHES.

Two articles on this subject are epitomized in the *Deutsche Medizinal-Zeitung* for November 12. One of them, by M. Leon Perrin, was published in the *Annales de dermatologie de syphiligraphie*,, and the other, by M. Voituriez, appeared in the *Journal des sciences médicales de Lille.* Of genuine gonorrhœal rashes—*i. e.*, rashes not due to the ingestion of some drug—M. Perrin has been able to find only twenty cases on record, and to them he adds two that have come under his own observation. Dr. A. Blaschke, who summarizes M. Voituriez's article, says, that he himself has never seen a case. According to Voituriez, the gonorrhœal exanthem resembles that of measles or that of scarlet fever and is followed by desquamation, whereas, a copaiba rash is more like urticaria or a polymorphous eruption. The gonorrhœal rash may last for a week, and is usually generalized and often accompanied by fever and angina.

HYPNOTISM AND ELECTRO-MAGNETISM.

In delivering the Saturday evening address at Toynbee Hall last week, Mr. Ernest Hart took Hypnotism and Electro-Magnetism for the subject of his discourse. He traced the history of hypnotic and mesmeric practices through ancient European and Asiatic nations, as well as the existing aborigines of Africa and among the demoniacs of the Middle Age. Sketching the decent of the doctrine of animal magnetism from Paracelsus (who regarded it as an emanation of the divine fluid) to Hausen, Mesmer, Puysègur, and Faria, to Grimes, Darling, and Elliotson in America and England, he endeavored to disengage the facts from the delusions and impostures with which the subject always has been, and is still surrounded. He showed that the term "animal magnetism" is a delusion, an example of the common practice of using a word which has no meaning to explain facts which are not understood. From the results of personal investigation of many years' observation, and of experiment on animals he showed that all the external causes commonly alleged to be efficient, such as the will of the operator, or any sort of fluid—magnetic, vital, or psychical—might be successively eliminated without in any way affecting the success of the result. Hypnotism and all its aliases—mesmeric, electro-biological, or "magnetic"—he showed to be subjective; second sight, clairvoyance, and thought transference to be impostures or self-deceptions. He then discussed the remarkable effects of suggestion on the hypnotic, which transcended many of the marvels and impostures of the stage-impostors who abused and imitated them. Referring to the long series of efforts to render hypnotism of therapeutic value, although they were old and conducted by a number of abel men, he pointed out how meagre and valueless they were in the ablest hands, whether of Bernheim or Charcot, and how little promise there was in them. Finally, he referred to the evil results of hypnotic practices in the hands of unscrupulous or unskilled persons, their mischief on stage performances, and called for their prohibition in such hands in this as in Continental countries. The address was received with profound attention and frequent applause, and has been widely commented on with approval in the press.—*Brit. Med. Jour.*

THE PARASITE OF IRREGULAR MALARIAL FEVERS.

Dr. M. W. Sakharoff (*Ann. de l'Inst. Pasteur*, July 25th, 1891) has a note on certain parasites occurring in the blood of patients suffering from irregular malarial attacks. These are different from those found in the "regular" fevers, being small pale bodies enclosed in the blood corpuscles, endowed with amœboid movements, and assuming a round shape when at rest. In course of development this amœboid condition undergoes the following modifications: Pigment granules appear, mobility is gradually lost, and the form becomes round. The granules unite into a mass at one side or in the middle of the parasite, and a nucleus previously visible can be no longer seen. During this time the parasite increases in size but always remains smaller than the blood corpuscle, of which a large portion is unoccupied. After a time fission commences, and this may be observed in blood drawn from the finger (the parasite described by Marchiafava in connection with regular malaria only divides in the internal organs and not in shed blood). This fission takes place in the interior of the corpuscles, after which the segments, from four to sixteen

in number, escape, and either remain free or become enclosed in leucocytes. In these latter, further development very rarely occurs. This is the normal life history, but two modifications may be at times observed: (1) Sometimes the course is more rapid and fission begins before pigment formation; (2) at other times new crescentic forms appear, and the disease assumes a chronic course. This is a highly interesting form, and one about which there has been some controversy. The author believes (1) that in cases in which these occur the fever seldom assumes a recurrent form. He considers (2) that usually these crescentic bodies are not developed, although at the commencement the amœboid parasites may be present in enormous numbers. He states also (3) that these crescentic bodies may be found in the blood of patients suffering from an irregular attack, but are very seldom seen in the course of a regular malaria. These crescents change gradually into oval or round bodies. Generally also, as the author has proved by actual observation, some of these round bodies develop a number of motile filaments, at least in preparations outside the body; finally they disappear and leave no trace. Attempts to cultivate the parasites have all failed. Fowls also showed themselves insusceptible, and the parasite has not been found in their blood although these are said to suffer from malaria. In the blood of some geese, however, affected in an extremely malarial district of the Caucasus, the author found a hitherto undescribed spiral parasite. He is making further researches on this parasite.—*Brit. Med. Jour.*

THE TWO TYPES OF AORTIC INSUFFICIENCY.

In a critical review of the subject of aortic insufficiency by Dr. Easton Lyon (*Gazette des Hôpitaux*, June 13, 1891), stress is laid upon the fact that there are two rather distinct types of this order which ought to be recognized. These are the endocardiac type and the aortic type. The former affects especially young subjects, it most often follows rheumatism, it may remain stationary for years, and it is before all an affection of the heart. The latter affects older subjects; it is related to arterial sclerosis, and is especially a disease of the arteries. While these two types may not always be distinct, and may even run together, yet the pathological and clinical difference is a distinct and real one.

Taking up the subject of the endocardiac form, Dr. Lyon goes over, first, the question of its etiology. Here the two great factors are trauma and infection, the infection being usually rheumatic fever.

Rheumatism, according to the French statistics, affects the heart's valves in about one-third of all cases, and in about one-third of these the aortic valves are attacked. The infection of typhoid, scarlatina, and erysipelas sometimes acts similarly. Taruma is a rare cause. Three quarters of the cases are males and most of these are adults. The lesions of the valves are those due to acute and to chronic endocarditis. Under the former head we have ulcerations, vegetations, and valvular aneurisms; under the latter a reticulated condition, rupture, and valvular aneurism. The aorta is healthy, but the heart is dilated and hypertrophied.

It is not necessary to go into the detailed analysis of the symptoms as given by Dr. Lyon, since they are familiar to all. The capillary pulse, the tonsillar pulse, and the retinal and pharyngeal pulsations, are curious and striking symptoms sometimes observed in this type.

Aortic insufficiency of cardiac origin is thought to be the form of heart disease most compatible with long life, provided the patient has no other valves involved, and does not have to lead a laborious life. Cures have even been claimed by Potain and others. Sudden death is rare, though perhaps more frequent than in mitral disease. It may be due either to embolism or heart failure.

In the matter of treatment, Dr. Lyon asserts that digitalis is absolutely contra-indicated, and that iodide of potassium does no good. Hygienic measures and opium are the only things recommended, and if this represents the limits of French therapy one must consider it rather barren.

Aortic insufficiency of the arterial type is really but one manifestation of a generalized arterial sclerosis. It is caused by the infectious toxic agents, and diathetic poisons; hereditary influence is also a factor. The valves are indurated and sclerosed, the orifice dilated, the heart hyperthophied. The aorta is always dilated

and incrusted with atheromatous plaques. There is excessive arterial tension increase of dullness at the base of the heart, a double murmur, and often local pain on percussion. The subjective symptoms are much more varied and severe than is the case in the cardiac form ; anginal attacks, vertigo, syncope, dyspnœa, palpitations. Death more often occurs suddenly from heart failure, cerebral hæmorrhage, or from uræmia.

The treatment here recommended is iodide of potassium, trinitrine, caffeine, milk diet, and intestinal antisepsis.—*Med. Rec.*

PANCREATIC DIABETES.

Rendu (*La Semaine Medicale*, March 25, 1891), has described the varieties of glycosuria. Sometimes glycosuria is transient; the urine of certain individuals, over-fatigued physically and especially mentally, from time to time contains traces of sugar. Such glycosuria disappears after some days of rest and seems to have no serious significance. It is the same with the glycosuria observed in some acute conditions, as in poisoning by the vapors of charcoal. In the cases indicated, the glycosuria is probably a result of congestion of the bulb, and is not true diabetes.

Diabetes is probably always of nervous origin. Rendu is convinced that whenever glycosuria exists, the bulb is involved. In this category belong the cases of Claude Bernard, in which the diabetes was the functional expression of a lesion of the medulla or the fourth ventricle. Leudet has reported cases of basilar meningitis with glycosuria; in some cases of diabetes Luys has post-mortem found marked congestion of the floor of the fourth ventricle; in still other instances, tumors have been found in the same region.

The most important and the most frequent form of diabetes is constitutional or diathetic, of which there are two varieties: adipose or gouty, and thin and pancreatic. The diabetes of the adipose or gouty is hereditary; it may continue for years without impairing the general health. It frequently alternates or coincides with other articular or gouty manifestations, or with such conditions as external hemorrhoids, eczema, migraine, or epistaxis; the patients are also often asthmatic. Some marked differences exist between these two types of diabetes. Gouty diabetes is insidious in onset; thirst may be absent; furuncles may appear, or an existing wound cicatrizes slowly; there may be itching of the genitalia; there are flashes of heat, or there is insomnia. The quantity of the urine passed during the twenty-four hours does not usually exceed five litres (five quarts) with a maximum of from thirty to forty grams (from an ounce to an ounce and a quarter) of sugar per litre; emaciation does not usually result; finally, the quantity of sugar in the urine is readily controlled by treatment. Each year after a sojourn at Vichy or at Carlsbad, the sugar completely disappears from the urine, to reappear at the end of some months. Such patients, however, may live for many years without accident, save perhaps itching or an outbreak of furuncles. They must, however, be regarded as invalids, as in them surgical or medical disorders may assume a grave character and rapidly terminate fatally. In these cases there is nearly always a psychic cause for the condition—a strong emotion, or financial loss. The nervous system seems to play an important rôle. In some cases bulbar manifestations are seen, as, *e. g.*, albuminuria or polyuria, alternating or coinciding with the glycosuria.

The manifestations of pancreatic diabetes differ from the preceding. The patients are neither diathetic nor predisposed; suddenly, without apparent cause, without prodromes, grave diabetes is evident. Polydipsia associated with polyuria develops in the midst of apparent health, and a condition pronounced debility is soon reached. In some patients intestinal disorders, paroxysmal diarrhœa, ill-defined chronic enteritis, with rapid loss of strength, usher in the disease. The stools may contain free fat. The onset may be marked by cerebral disturbance, such as vertigo, somnolence or insomnia. Premature and absolute impotence not dependent upon general paralysis or locomotor ataxia should create a suspicion of diabetes. The patellar reflex may be abolished. In addition to the excessive thirst and appetite there is an unusual sense of fatigue, at first physical and soon intellectual; the patient becomes apathetic; in some cases moral depression may be the first indication of diabetes. While in the diabetes of the gouty or adipose the quantity

of urine rarely exceeds three or four liters, in pancreatic diabetes it is often much greater. The degree of azoturia is proportional to the degree of glycosuria. Trophic disorders are prominent. Lesions of the retina are observed; the teeth and hair fall out; finally, a series of digestive disorders arise that lead to rapid emaciation. Tuberculosis frequently develops.

Lesions of the pancreas were long ago observed in cases of diabetes. In five cases of nine, Frerichs has noticed atrophy of the pancreas; while the lesions described have not in all cases been identical, they have all been associated with destruction of the organ. Atrophy is frequent; a sclerotic condition, either pericanalicular or perivascular, is often found. In some instances the volume of the pancreas was normal, but the glandular element was completely altered or had disappeared. In dogs, extirpation of the pancreas has been followed by diabetes with polyuria, glycosuria, and emaciation.

It seems, then, that a pathological relation exists between the condition of the pancreas and diabetes—a relation, however, the details of which are not yet understood. It is also probable that the polyuria and glycosuria are more common as a result of lesions of the fourth ventricle. The prognosis of pancreatic diabetes is much less favorable than that of diabetes in the adipose or gouty. In the pancreatic form therapeutics is entirely powerless; slight amelioration may be obtained from the administration of opium, antipyrine, arsenic, lithium, or the bromides; but the glycosuria cannot be made to disappear completely. In diabetes of the adipose, medication is speedily successful.—*News.*

DISSEMINATED SCLEROSIS.

C. Zimmermann (*Archiv. of Ophth.*, vol. xx, No. 3, 1891) reports a case which he diagnosed to be disseminated sclerosis mainly from the association of partial atrophy of both optic discs with spastic paraplegia. The man was a painter, aged 26, and first came under treatment in 1886. He had suffered from dimness of vision in the right eye and diplopia for several weeks. V. R.=$\frac{15}{70}$; V. L. =1. Visual fields and perception of colors normal. Pupils equal; irides acted normally with light; the temporal two-thirds of both discs were perfectly white; all the vessels were crowded to the normally colored nasal third. There was crossed diplopia, increasing on movement to the left, from paresis of the right internal rectus. At the end of two months' treatment with strychnine and potassium iodide, V. =1. in each eye, diplopia, absent, ophthalmoscopic appearances unchanged. In March, 1891, the patient displayed the characteristic signs of primary spastic paraplegia, including the abdominal muscles and to a certain extent those of the right upper limb. In the latter there were paræthesiæ, a large anæsthetic patch on the arm, and partial anæsthesia over much of the ulnar nerve territory. Speech was hasty. Vision remained normal; atrophy of discs unchanged. Oppenheim first directed attention to optic nerve atrophy in spastic paraplegia. In his work on the subject he showed that disseminated sclerosis presents the clinical features of primary spastic paraplegia much more frequently than is commonly recognized, and that the affection of the optic nerve is the one sign that may ensure the diagnosis. Uhthoff has found that in consecutive atrophy of the optic nerve many of the axis cylinders escape lesion. That fact has been confirmed by Oppenheim, and probably explains the absence of visual impairment.—*Brit. Med. Jour.*

SURGERY.

THE PRESENT STATUS IN BRAIN SURGERY, BASED ON THE PRACTICE OF PHILADELPHIA SURGEONS.

In the *University Medical Magazine*, Oct. 1891. Dr. D. Hayes Agnew presents a paper containing fifty-seven cases of trephining for traumatic epilepsy. Forty-six of the patients were males, four were females, and in seven the sex is unknown. Of these fifty-seven cases, forty-one recovered from the operation, four died, while in the remaining twelve the result is not given. The ages varied from seven to forty-nine years. The mortality did not exceed seven per cent. Thirty-two experienced temporary benefit; nine obtained no relief; four passed out of observation; four were operated on too recently to ex-

press any opinion ; four were cured, and four died. The author concludes that traumatic epilepsy is practically incurable by surgical operations, and that a considerable number of such cases had better be relegated to the domain of pure medicine. But he believes that a certain number of patients in this class, on whom internal remedies have no controlling influence, may with propriety be operated on as a palliative measure. He assumes that surgery is responsible for the great majority of traumatic epileptics, and the old doctrine that depressed fractures of the skull without symptoms required no operative interference, in his opinion, has been the cause of very many of the unfortunate sequels of head injuries.

ANTISEPSIS FOR THE HANDS.

The steps of Dr. McLean's process are: 1. The hands, having been thoroughly cleansed, are to be held for two minutes in a solution of the permanganate of potash, 5 parts to 100, after which the hands should be rinsed in clear water. 2. Hold the hands for one minute in a hypophosphate of soda solution, one ounce to the pint. 3. While this is being done add the oxalic-acid solution, ½ ounce to the pint of water. This causes a double chemical combination, whereby an oxalate of sodium and sulphur dioxide are formed, which have powerful decolorizing and disinfecting properties. The permanganate stains are promptly removed from skin and nails; after again rinsing the hands in sterilized water they are ready to come in contact with either an exposed serous or a lacerated mucous membrane. The hands may then be regarded as both surgically and obstetrically clean.—*Journal American Medical Association.*

INTERNAL STRANGULATION.

Mr. Arbuthnot Lane in a recent paper on the varying modes in which a strangulated loop of bowel reacted to the constricting medium. He narrated two cases of strangulated hernia, remarkable for the extreme sharpness of the constricting edge. In one, the loop of bowel had passed along with a piece of omentum through a small aperture. The bowel in the sac was not much congested. The distal portion of the loop was shielded from the sharp constricting margin by the omentum, but more than three-quarters of the circumference of the proximal portion of the gut had been subject to its pressure, and had by a process of ulceration been deprived of all but its peritoneal coat for a breadth of nearly one-eighth of an inch. This coat appeared very thin, but was not perforated. Mr. Lane invaginated the damaged portion of the circumference of the bowel into that beyond and retained it with sutures. The man recovered. The second case was one of reduction *en masse*, with a constricting medium precisely similar to that in the preceding case, but both proximal and distal ends of the loop were so deeply ulcerated as to leave only the peritoneal coat along the line of constriction; and though there was no obvious perforation, the fluid in the sac and that in the abdominal cavity in the vicinity of the hernia smelt strongly of fæces. The loop was excised, and the ends of the bowel approximated by Senn's method. Symptoms of peritonitis, which were only local before the operation, soon became general, and death ensued on the following day. In this, as in the first case, the loop of bowel showed very little change except at the point of constriction. It would have been impossible to have performed the operation at all, owing to the very enfeebled state of the patient, but for the free intravenous injection of saline solution. With these two cases he contrasted the condition of bowel seen in strangulation hernia, when the constricting medium was broad and produced no local distinctive change in the gut. In such, the condition of the strangulated loop simulated that resulting from the experimental ligature of a loop of bowel by a piece of broad tape or gauze, the bowel becoming intensely congested, thick, leathery, inelastic, and, for a longer or shorter time after the constriction had been removed, functionless. If it were subjected to the influence of the constriction for a sufficiently long time, gangrene took place at the convexity of the loop, commencing at a point most distant from the constriction. He pointed out that between these two extremes any number of intermediate conditions and combinations occurred, and he indicated their importance surgically. The freedom of the bowel from congestion in the two cases described, he explained in this manner: When the loop first be-

came strangulated, it probably soon became more or less congested, but the very sharp constricting margin produced rapid destruction of the soft mucous and muscular coats of the bowel by its pressure, and their consequent disappearance enabled the veins which were originally constricted to dilate, and to occupy the space filled originally by these bulky coats, so the back flow of blood from the bowel was carried on satisfactorily, the loop recovering its normal appearance more or less completely and rapidly.

OBSTETRICS.

ON RAPID DILATATION OF THE UTERUS FOR DIAGNOSIS AND TREATMENT IN CASES OF UTERINE HÆMORRHAGE.

Dr. Amand Ruth read a paper on this subject at a meeting of the London Medical Society based on 52 consecutive cases; 42 out of the total 52 cases (18 per cent.) were found, after dilatation, to have a removable intrauterine cause for the hæmorrhage. If in a series of cases set apart for Apostoli's treatment the uterus were first explored and then tabulated according to whether the fibroids were intramural, submucous, and polypoid, or whether a fungous endometritis were present, and the result of the treatment thus recorded, the class of cases in which Apostoli's treatment was appropriate would soon be known, and the previous dilatation would have enabled the operator to ascertain the exact spot where the current could be best applied. Long-handled metallic graduated bougies were considered the best dilators, under deep anæsthesia, with rigid antisepsis. The question of tubal dilatation complicating uterine disease was discussed with reference to rapid dilatation. The 52 cases consisted of 13 placental or membranous retentions, 5 polypi, 2 polypi and fungous endometritis, 2 fibroids without fungous endometritis, 7 fibroids with fungous endometritis, 8 fungous endometritis, 5 granular endometritis, 5 malignant disease; in 5 no intrauterine cause was found. The following conclusions were considered to be proved: 1. That where there was profuse menorrhagia, and more especially where metrorrhagia was also present without obvious cause, the cavity of the uterus should be explored. 2. That the best way to explore the uterine cavity was to rapidly dilate the cervix with graduated bougies under anæsthesia. 3. That with rigid antisepsis there was practically no risk, and very rarely any subsequest pyrexia, unless malignant disease or salpingitis was present. 4. That even when tubal disease was present or suspected, exploratory dilatation of the cervix for metrorrhagia of apparently intrauterine origin was not necessarily contraindicated, salpingitis being often secondary to and aggravated by intrauterine disease. Here, again, antisepsis was all important. 5. That where fibroids of the uterus were evidently present the immediate cause of the hæmorrhage might be a removable one, such as a co-existing polypus or a fungous endometritis, and that, therefore, the uterine cavity should be, when practicable, explored before removal of the appendages or hysterectomy was entertained. 6. That in some cases dilatation alone sufficed to greatly relieve both the hæmorrhage and pain. 7. That if an exploratory dilatation were more often adopted prior to the employment of Apostoli's treatment, it would tend to a more exact knowledge of its applicability, and put its use on a more scientific basis.

PORRO'S OPERATION: RETROPERITONEAL TREATMENT OF PEDICLE.

Hans v. Woerz (*Centralbl. f. Gynak.*, No 5, 1892) urges the advantages of sinking the pedicle after Porro's operation. Professor Chrobak operated in a case of mollities in October, 1891; the patient was aged 36, and in her sixth pregnancy; the pelvis was much contracted, the urine free from albumen. The uterus was drawn out and two large flaps of peritoneum dissected off from before and behind. As the serous membrane was thick and vascular and but loosely connected with the muscular coat of the pregnant uterus, its dissection was very easy. A vertical incision was then made in the uterus, the elastic ligature being applied, and a living full-term fœtus removed. The placenta and membranes were removed. The broad ligaments were secured after the usual manner. Then the uterus was cut away above the ligature. A large tampon of iodo-

form gause was pushed into the vagina so as to lie against the os. The raw surface of the cervix was cauterized with Paquelin's instrument and the uterine arteries secured by transfixion. The elastic ligature was removed: some vessels bled and had to be tied, but much of the tissue of the cervix had to be trimmed away and the cautery applied once more. An iodoform point was thrust into the cervical canal from the abdominal aspect. Some vessels began to bleed and were secured. The cervix and the flaps had retracted considerably by this time. The flaps were carefully sewn over the raw surface with interrupted silk ligatures. The abdominal wound was then closed. The patient recovered. Two months later the cervix felt perfectly movable, there being no inflammatory infiltration in the pelvis. The removal of the appendages had already checked the advance of the mollities: the bones no longer ached as before.—*Brit. Med. Jour.*

MULTIPLE ARTHRITIS CAUSING PREMATURE LABOR.

The clinical bearing of arthritis during pregnancy is considered by Tracon and Bué in the *Archives de Tocologie*, 1892, No. 1. They report two cases as follows: The first was a woman pregnant for the second time, who was subject to sudden cold followed by pains in the lower extremities, especially in the right knee. She entered a hospital where she was observed to have fever for several days. The pains passed through the lower extremities to the upper, the left shoulder becoming especially involved. On entering the Maternity Hospital her rheumatic affection was most prominent in the thumb of the right hand, which was immovable and very painful to the touch. The right knee was also very painful and partly ankylosed. The patient had abundant leucorrhœal discharge but otherwise revealed nothing of interest. The induction of labor was determined upon by the method of warm antiseptic douches. Soon after delivery the pains began to grow less, and finally disappeared under treatment by counter-irritation. The child suffered from pain in the left arm, which caused it to immobilize the limb.

The second case was that of a woman aged twenty-seven years. She was taken during pregnancy with inflammation of the right knee, which had been previously immobilized by a surgeon. The arthritis was considered gonorrhœal.

GYNECOLOGY.

METRORRHAGIA.

Hydrastinin hydrochlorate in doses of a third of a grain, every six or eight hours, is recommended as a useful remedy in the treatment of metrorrhagia dependent upon congestion or catarrhal inflammation of the uterus. The good results should be perceptible in the course of two or three days. —*Berlin, klin. Wochenschr.*, No. 7.

BACTERIOLOGY OF ENDOMETRITIS.

In order to investigate the bacteriology of endometritis, Dr. Brandt of St. Petersburgh recently examined twenty-five cases, including hæmorrhagic, catarrhal, gonorrhœal, and septic forms. After carefully cleansing the external genitals, the vagina, and the cervical canal with a solution of corrosive sublimate of the strength of 1 in 1000, with alcohol and with ether, preliminary bacteriological observations on scrapings from the cervical canal invariably giving negative results, the internal surface of the uterus was scraped with a curette, and dry preparations as well as cultures in agar and gelatine were made. The plate method was likewise employed, as were inoculations in animals. The portions of mucous membrane brought away were also carefully examined with the microscope. In almost all cases microbes were found, both pathogenic and non-pathogenic—the former, however, preponderating. Of these both cluster and chain cocci were met with, amongst the non-pathogenic bacteria there were occasionally bacilli, but most commonly cocci. It was remarked that cases where pyogenic microbes were found were not clinically distinguishable from others where none could be detected: these pyogenic microbes, however, when injected into animals invariably produced both local and general symptoms, such as abscesses and a rise of temperature. Sometimes but by no means always, microbes were seen in the substance of the mucous membrane.—*Lancet.*

EFFECTS OF CAUSTICS ON THE ENDOMETRIUM.

L. M. Bossi (*Nouvelles Arch. d'Obstet. et de Gyénc.*, January 25th, 1892) continues his researches, which demonstrate the very definite effects of strong caustics, such as chloride of zinc points, on the endometrium. The caustic does not simply destroy the mucous membrane forever; on the contrary, the endometrium is reproduced, but in a morbid form. The chief feature in this change is a violent inflammatory process, which causes the orifices of the uterine tubular glands to be obliterated. The glands then undergo cystic changes. Secondary atrophy of the endometrium may occur, but more frequently that membrane is reproduced with the abnormal addition of numerous cysts, which bear glandular epithelium and increase in size. The application of the curette, on the other hand, gives rise to none of these bad and permanent results. The epithelium of the endometrium is reproduced, and no obliteration of the orifices of the glands, no subsequent cystic changes occur.—*Brit. Med. Jour.*

APHTHÆ OR "THRUSH" OF THE VULVA.

P. Gilulini (*Centralbl. f. Gynäk.*, December 26th, 1891) describes a case of aphthæ, or rather an eruption identical with the parasitic stomatitis, or "thrush" of infants, which occurred in a woman, aged 24, in the second month of pregnancy. Two months previous one of her children had an attack of thrush. The patient suddenly felt very ill, and suffered from intolerable burning and itching in the vulva. The labia majora and minora were found much swollen. The labia minora were of a deep red colour, and dotted over with little white spots, which disappeared on brushing the surface gently with wool, leaving behind very superficial breaches of the epithelium. The entrance to the vagina was as yet free. A thick yellow discharge proceeded from the vagina. Although the parts were at once washed with a solution of sulphate of zinc and carbolic acid, the disease made great progress, and on the next day the entire vulva and part of the vagina appeared as though covered with a thin film-like layer of curds. The œdema of the vulva had increased, micturition caused pain and burning sensation, and the temperature was high. Diphtheria was suspected, and some of the milky film was examined, when the *oïdium* or *saccharomyces albicans* was discovered. Lead lotions were applied to the parts, and the vagina was syringed with a solution of carbolate of lime. In about five days the patient was cured. The urine was free from sugar.—*Brit. Med. Jour.*

PEDIATRICS.

PAPOID IN DIPHTHERIA.

Dr. I. N. Love finds that an application destructive to the membrane and at the same time germicidal in its effects, is a vegetable product derived from the Papaya Carica and possessed of marked digestive powers, known as papoid. It comes in the form of a powder, a small portion of which should be used at intervals of one, two or three hours as may be desired, according to the extent of the deposit which we may desire to remove. The same should be made into a paste with a small quantity of water and applied with a fine camel's hair brush. I have found this product very satisfactory as a destroyer of the membrane. An additional advantage of this application is that such parts as may be swallowed will serve to help nature to digest whatever food there may be in the alimentary canal. This is not an unimportant point, and right here, in order to emphasize the importance of nutrition, we will anticipate that which will be considered later, and suggest that in the beginning of the treatment, the alimentary canal should be promptly emptied and placed in the best possible shape for the securement of nutrition, because we have a "battle of the cells" before us, and the greatest enemy to the Klebs-Löffler bacillus, or any other, is well-nourished blood. Insist upon an abundance of nourishment from the start. Food that is in a form ready to be promptly assimilated, such as eggs, peptonized milk with beef peptonoids, bovinine and raw scraped beef, together with fresh well-ripened fruits should be given ad libitum. Another delicacy which we can give them, and one that they are fond of, is ice cream, and if we can have it made at home, it is better for then we can be sure that the best and purest cream is used. Ice cream, by the manner of prep-

aration, is rendered more digestible than cream would otherwise be without this treatment. It is grateful to the palate, cooling to the burning throat, and may be utilized as one of the rewards which we can offer to our little patient, for the taking of our medicines. We will not go far wrong if during the progress of our case we give from one to two grains of Papoid just referred to, either in the form of a powder, in a capsule, in solution or it may be mixed with a little powdered chocolate and sugar and taken as a bonbon. Given in this way it serves to help the digestive apparatus in the important work that is before it.—*Medical Mirror.*

FOR COLIC.

℞

Tinct. opii (deodorata)	5 j
Chloroform	5 j
Spts. peppermint	5 j
Tinct. podophyllin	5 j

M. Sig.—Teaspoonful in one-third of a glass of sweetened hot water; children in proportion; repeating the dose every half hour or hour until relieved, increasing the amount if necessary. As an extemporaneous prescription the above is a great favorite of mine.

The tincture of podophyllin is easily made by percolation. Place in the percolator sixteen grains of the drug, previously moistened with alcohol, then pour on a sufficient amount to make two ounces. If preferred it may be made by macerating the podophyllin in two ounces of alcohol for seven days, then filtering through paper, adding alcohol sufficient to make two ounces of the tincture.

T. G. Stephens, M. D.—*In Medical Science.*

CHRONIC PERITONITIS IN CHILDREN.

Henoch, in a paper on chronic peritonitis in children (*Deutsche med. Woch.*, January 7th, 1892) directs attention to some of the rarer forms and causes. He observes that a certain small proportion of the cases are due to trauma, and relates an instance in which enormous ascites followed without pain or tenderness on an injury to the belly; in this case there was extreme plastic peritonitis. He also relates a case in a girl aged 11, of peritonitis coming on about two months after measles; the amount of fluid which collected was very large. She had been tapped twice before coming under Henoch's care, but at the third tapping 1¼ gallon was withdrawn; the fluid again collected, but subsequently diminished spontaneously, and the child made a perfect recovery. The diagnosis of such a case is difficult, but after withdrawal of the fluid it could be ascertained that the abdominal organs presentedi no evidence of enlargement, and that in particular the liver was not altered in size. The treatment under which the girl recovered was hot air baths, and painting of the abdomen with iodoform collodion. Henoch admits that the treatment of chronic peritonitis, and especially of tuberculous peritonitis, by medical measures is very unsatisfactory; hydropathic packing of the belly, painting with iodoform and tincture of iodine, and the administration of iodide of iron are all useless, and tapping commonly affords only temporary relief. As to the alleged cures by laparotomy, he doubts their permanency, and mentions a case which illustrates the liability to mistaken diagnosis; in this case the child, a girl aged 5, presented well marked ascites, and exudation into the left pleura; the latter disappeared under treatment, but the former did not; laparotomy was performed and the peritoneum was found to be covered with small reddish-gray granulations; some of these granulations removed and carefully examined proved not to be tuberculous; the child made a rapid and complete recovery. Henoch considers that this was a case of simple peritonitis accompanied by the formation of small fibromata, as has been observed occasionally in women. He states that on two occasions he has seen a similar condition in the pleura; he compares it with the case of peritonitis following injury, in which there was a remarkable thickening of the peritoneum. In discussing Henoch's paper, Baginsky observed that simple peritonitis seemed sometimes to be secondary to intestinal catarrh, and with reference to treatment spoke very unfavorably of laparotomy. He had the operation performed in two cases, but would never again submit a young child suffering from tuberculous peritonitis to it. In older children, and in cases in which there was a large amount of fluid, it might be justifiable. Henoch considered that the operation was always justifiable in the early stage if the other organs were free from evidence of tuberculosis, and ob-

served that no other treatment had ever succeeded in giving such good results in undoubted tuberculous peritonitis, as had been reported by competent surgeons after laparotomy.—*Brit. Med. Jour.*

ANTIPYRINE IN WHOOPING-COUGH.

Dr. E. Feer (*Medical Press*, 1892, No. 2749, p. 24) believes that this remedy should have the first place in the treatment of whooping cough. Eighty cases were under observation and the dose was in proportion of that of fifteen grains for a ten-year old child, given morning and evening. When several children in the family were affected with this disease the results were not so good (mutual reinfection—Professor Hagenbach). The remedy was beneficial in four-fifths of the cases. It cannot be ascertained whether it acts as a germicide or as a sedative—very likely the latter, as Demme and Sèe have proved that it has a direct restrictive influence upon the reflexes.

GROWING FEVER.

Barbillion has written a long article on the so-called growing fever of children. His conclusions are that the fever of growth no more exists than does a fever of obesity or of senility. The symptoms which have been grouped under this head are due to a great variety of causes, such as are seen in ephemeral fever, stomach troubles, acute osteomyelitis and other pathological lesions. —*Rev. Mensuelle des Maladies de l'enfance*, January, 1892.

HYGIENE.

THE ALLEGED INCREASE OF INSANITY.

A very interesting report was presented a few days ago to the half-yearly statutory meeting of the Barony Parochial Board of Glasgow by the Acting Inspector of Poor. The board possesses a lunatic asylum at Woodilee, near Glasgow. In five years the cost of this institution has increased by £3,600, and in the same period the cost of boarding out lunatics has increased by £1,241, a total increase of £4,841. This, the inspector believes, does not indicate an actual increase of insanity but that more of the insane poor, especially old and incurable cases, are being handed over to the parochial authorities. In the half-year ending February 14th, 1892, the number of lunatics was greater by 93 than in the same period for 1886-87. A very noteworthy point was a coincident decrease in the number of paupers, to the extent of 916, implying a total saving to the rates of £3,889, equal to 1d. per £1. In six months, the worst portion of the year, the decrease in the roll of paupers was 74, attributed to increased advantage being taken of insurance and other benefit societies, to the operation of philanthropic and charitable agencies, and to a greatly improved condition of the working classes as a whole. To the discriminating action of the Relief Committee in selecting the best form of relief suitable to each applicant the result is also largely attributed. For it is noticeable that while there are 142 fewer inmates in the ordinary wards of the poor-house there are 61 more inmates of the hospital. The Inspector suggests that the development of the hospital side of the poor-house by an extension of trained sick nursing and by a more complete separation of the hospital from the poor-house will force itself upon the consideration of Poor-law authorities within the next few years.—*Brit. Med. Jour.*

VARIOLA AND VACCINE.

Dr. Chauveau, Professor in the Museum of Natural History of Paris, communicated to the public a *rèsumè* of his researches on the subject of the transformation of the virus of small pox into vaccinia, or vaccine:—

It is well known that a number of physicians and most of the people believe that vaccine, or vaccinia, produced from the bovine species for the purpose of vaccination against smallpox, is nothing else than smallpox virus itself, modified by successive passages through the animal organism. The Commission of Lyons, France, under the direction of Dr. Chauveau, has established, it seems very positively, that (as has long been believed by most thinking scientists) this is not the case. The virus used for vaccination (cow-pox or horse-pox) is certainly a close relative of the virus of smallpox, and it is perhaps legitimate to admit that they were derived from a common source or from one another, in centuries past. But at this time they are a

distinct species, and it seems impossible to reduce them to a single species by the known methods and artifices of experimentation. Inoculations of smallpox in the horse and in cattle produce variola in them, and the introduction of the virus thus produced in these animals, gives to a man variola itself. It was found that the animals inoculated with smallpox became immune against vaccinia, just the same as man inoculated with vaccinia becomes immune against variola.

The symptoms of these different viruses in animals vary considerably, and there can be no mistake made in the diagnosis.

Messrs. Haccius and Eternod of the Vaccinal Institute of Lancy, Geneva, produce a vaccinal lymph cultivated on calf, which is said to be transformed from variola, and not very long ago published their conclusion that variola and vaccinia are probably identical. M. Chauveau, in experimenting with this lymph, found that it contained, in reality, the true virus of smallpox, and therefore it is a dangerous article to use for vaccination. Vaccine, then, should not for practical purposes be considered as an attenuated variola virus, for the two are now distinct, and both are strong viruses of their respective species, whatever their origin may have been.

ARSENIC IN COMMON LIFE.

This was the subject of a recent address by Prof. C. F. Chandler before the Academy of Medicine, and abstracted in the *Medical Record*, Nov. 28, 1891. He took the ground that there is no danger to be feared from arsenical poisioning from living in rooms papered with arsenical wall-papers, that the quantity of arsenic that could be given off by such a wall-paper could not possibly do any harm. He gave a critical review of the various eases that have been collected by the Board of Health of Massachusetts, in which he finds no proof of arsenical poisoning.

He could find no record of a case of arsenical poisoning in any of the factories where arsenical wall-papers are made. He said that the symptoms of arsenical poisoning are not so specific that physicians could usually make a positive diagnosis of arsenical poisoning.

Incidentally he remarked that there should be a law prohibiting undertakers from using arsenic in the embalming process.

THE DEADLY COLD BED.

If trustworthy statistics could be had of the number of persons who die every year or become permanently diseased from sleeping in damp or colds beds, they would probably be astonishing and appalling. It is a peril that constantly besets traveling men, and if they are wise they will invariably insist on having their beds aired and dried, even at the risk of causing much trouble to their landlord. But, according to *Good Housekeeping*, it is a peril that resides also in the home, and the cold "spare room" has slain its thousands of hapless guests, and will go on with its slaughter till people learn wisdom. Not only the guests, but the family, often suffer the penalty of sleeping in cold rooms and chilling their bodies, at a time when they need all their bodily heat, by getting between cold sheets. Even in warm summer weather a cold, damp bed will get in its deadly work. It is a needless peril, and the neglect to provide dry rooms and beds has in it the elements of murder and suicide.

MEDICAL CHEMISTRY.

THE PHENOMENA OF RANCIDIFICATION.

M. Ritsert has published in the *Revue Scientifique* a very interesting paper describing the experiments made by him to solve the question of the cause of the rancidification of fats. He first directed his attention to the micro-organisms always present in fats. Isolating these and sowing them upon sterilized fats, he found that no acids were produced, and further, that subsequent enumeration of micro-organisms demonstrated that these not only did not grow and increase in numbers, but that most of them actually perish when placed in contact with sterilized fats. The inoculation of sterilized fat with rancid fat produced the same negative results. These experiments eliminated the microbian theory of the origin of rancidity. On exposing the inoculated fats to the direct sunlight M Risert noticed that the bacteria, etc., died more rapidly than when the direct light was excluded, but at the same time the fat became rapidly rancid. Light, therefore, seemed to be a direct agent in rancidification. This point fixed, the experimenter next turned his attention to the atmos-

phere, or the gases which constitute it, and investigated whether it or they played any role in the phenomenon. Nitrogen and oxygen alone, either or both of them, have no effect *in the dark* upon fats, and nitrogen alone none in the light, but oxygen and light effect rancidification rapidly. Rancidity, then, is an oxidation, but one that is never produced in the absence of light. Hence, fats kept in absolute darkness will not become rancid.

ACTION OF BORAX ON CHLORAL.

Mr. Dujardin (*Bullet. Commerc.*, April, 1891), found that in preparing solutions containing borax and chloral, considerable depends on the temperature at which the compounds are brought together. At ordinary temperatures no change is observed; on warming, however, decomposition of the chloral takes place, a long-continued, slightly elevated temperature decomposing the chloral as effectually as a few minutes boiling. The decomposition in this case seems to be similar to that which takes place when an alkaline hydrate is used; at least chloroform is one of the decomposition products. In dispensing the two substances it is recommended to dissolve the borax, if necessary, by heat, and allow the solution to cool before adding the chloral.

BISMUTH SALICYLATE.

Duyk (*Bull. Soc. Pharm. Bruxelles*, Oct., 1891), proposes the following method for the preparation of bismuth salicylate: 100 gm. subnitrate of bismuth are treated for one or two days with one litre of water, to which 50 gms. water of ammonia had been added. After shaking sufficiently the subnitrate is completely changed into an oxide, which is collected and carefully washed with water. This oxide, after expression, is heated, under constant stirring, with 25 gms. powdered salicylic acid on a water-bath. When union has been effected, which is found by using litmus paper, the salicylate of bismuth is washed and then dried at a slightly elevated temperature.

REACTION OF SALICYLIC ACID.

In the *Pharmaceutische Post*, G. Kottmeyer asserts that the statement of Vortmann that the neutral salicylates give no precipitate with barium or calcium chloride, even on heating, or when ammonia or alcohol is added, is not true. Kottmeyer finds, on the contrary, that a 20 per cent. solution of sodium salicylate gives an immediate precipitate on shaking with a strong solution of calcium chloride; a 10 per cent. solution also gives a precipitate when ammonia is added; even a 1 per cent. solution, mixed with a few drops of strong calcium chloride solution, gives a precipitate on adding a little ammonia and shaking or warming. A slight precipitate is produced when barium chloride is added to a 20 per cent. solution of sodium salicylate, and a turbidity when a 10 per cent. solution is used.—*Ex.*

NEWS AND MISCELLANY.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

The second annual meeting of the American Electro-Therapeutic Association will be held in New York, October 4th, 5th, and 6th, 1892, at the N. Y. Academy of Medicine, 17 West 43rd St.

W. J. Morton, M. D., President.
H. R. Bigelow, M. D., Secretery.

VISITING NURSE SOCIETY. OFFICE, 1203 RACE STREET, PHILADELPHIA.

The Executive Committee would draw the attention of the public to the fact that not only is help offered by this Society to the poorer and working classes, but also that persons living in boarding houses or otherwise limited accommodations, and needing care, can obtain efficient nurses for daily visits. Thus, while greatly diminishing the expense of a resident attendant, they are also relieved of all responsibility regarding meals and lodgings, which under many circumstances almost doubles the wages given, besides being a burden to the patient.

During the past few years having met various applications for this branch of the work, and it having proved thoroughly satisfactory, the Society is enlarging its field in this direction.

The sum charged will be in proportion to the service required, a single visit will be one dollar an hour; special terms for a number of visits can be arranged with the head nurse.

SEDATIVE. ANODYNE.

EFFERVESCENT
BROMO
(WARNER & CO.)
SODA.

Caffein 1 Grain, Bromide Soda 30 Grains in each heaping teaspoonful.

USEFUL IN

Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness, and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromide Soda 30 grains, and Caffein 1 grain, in half a glass of water, to be repeated once after an interval of 30 minutes, if necessary.

ANTI-RHEUMATIC. SEDATIVE.

EFFERVESCENT.
BROMO
(WARNER & CO.)
LITHIA.

EACH DESSERTSPOONFUL CONTAINS:
℞ Salicylate Lith a 10 grains, and Bromide Soda 10 grains.

A REMEDY IN THE TREATMENT OF

RHEUMATISM, GOUTY DIATHESIS, ETC.

Dr. A. Garrod, the well-known English authority on Gout, who was the first physician to introduce the Lithia Salts in the treatment of Gouty Diathesis, states that their action is materially increased by being administered in a *freely diluted form.*

This effervescing salt of Lithia furnishes an easy and elegant way of applying Dr. Garrod's methods.

INGLUVIN

A SPECIFIC FOR VOMITING IN PREGNANCY.

A POWDER:—PRESCRIBED IN THE SAME MANNER, DOSES & COMBINATION AS PEPSIN

In Doses of from 10 to 20 Grains,

AND A POTENT AND RELIABLE REMEDY FOR THE CURE OF

Marasmus, Cholera Infantum, Indigestion, Dyspepsia and Sick Stomach,

caused from debility of that organ. It is superior to the Pepsin preparations, since it acts with more certainty, and effects cures where they fail.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels are:

1st—In quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the Proportion of Oil it contains.

3d—In mode of manipulation and thorough incorporation, rendering it Permanent and Palatable, and of proper consistence, about that of Rich Cream.

4th—In Size of Bottles, containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

ESTABLISHED 1830.

JOHN C. BAKER & CO., Philadelphia.

Most Powerful Purgative Water Known

CLINICAL LECTURES.

THE EXAMINATION OF YOUNG GIRLS.

By HENRY C. COE, M. D.,
PROFESSOR OF GYNÆCOLOGY, N. Y. POLYCLINIC.

Gentlemen:—This is a subject of considerable practical importance, on which I hold decided views which may seem at variance with some which you have heard expressed. I believe that a young unmarried woman ought not to have a pelvic examination and treatment unless in the judgment of the physician it becomes absolutely necessary; this should be the last step in the conduct of the case, not the first.

To illustrate my meaning, allow me to refer briefly to a typical case occuring in my own practice. A young lady of more than ordinary intelligence, but of nervous temperment, was sent to me recently by her physician, who inferred from her symptoms that she had some local trouble and desired me to make an examination, to which the patient was prepared to submit if necessary. She complained of backache, leucorrhœa and frequent and painful micturition, but had no severe localized pain, her menstruation was regular and painless and she presented anything but the appearance of an invalid. Reviewing her former history, I learned that last summer she had spent much of her time in the saddle on a Western ranch, sometimes riding forty miles a day without the slightest discomfort—a sufficient indication that she had no chronic uterine trouble. During the winter her habits had been sedentary, she had had obstinate constipation in consequence and defecation was followed by a throbbing pain in the rectum which suggested the possible presence of either a fissure or hæmorrhoids, which alone might account for all her pelvic symptoms. To her great relief, I told her that I preferred to try the effect of general treatment before making an examination. She had been using vaginal douches under the direction of her physician, but on inquiry, it was easy to understand why they had done no good, as she had used a small quantity of warm water while in a stooping posture. I directed her how to take copious injections of *hot* water, while only in the recumbent posture, with the hips elevated. She was to recline for an hour afterward. A laxative was prescribed with the advice that her bowels should be kept quite loose. After defecation hot applications were to be used, with a rectal suppository containing cocaine and a mild astringent.

The vesical symptoms were clearly of reflex origin, as the patient stated that they were always worse when her bowels were most constipated. There were no evidences of cystitis (the urine was examined and found to be normal), yet I have found that in these cases there is usually slight inflammation at the neck of the bladder, which is relieved by rendering the urine as bland and unirritating as possible. The simple remedy which I suggested was flax seed tea, containing a little cream of tartar, of which she was to drink three or four tumblerfuls daily. Having given careful directions with regard to diet, exercise, etc., I told the young lady to report in a week, when she was entirely relieved of the backache, leucorrhœa and vesical trouble, though the rectal symptoms still persisted and will probably require for their cure forcible dilatation of the sphincter ani under

anæsthesia, at the same time I shall be able to make a thorough vaginal examination.

My reference to anæsthesia has led me to the point which I wish to make and it is this: When you have a young girl with well-marked pelvic symptoms of long standing insist upon an examination under ether. Aside from the fact that you are able in this way alone to make an exact diagnosis, you may under some circumstances complete the treatment at the same time and thus save both the patient and yourselves further trouble. A contracted os may be dilated, an anteflexed uterus straightened, or a displacement corrected and a pessary inserted, while the presence of a diseased ovary or tube, or of a small intra-pelvic neoplasm, can be clearly determined and a decision reached regarding the necessity for a radical operation. Now there is a more important advantage still in such an examination—the elimination of nervous shock to the patient. It is inexplicable to me, the indifference which some men display in wounding the sensibilities of pure young maidens. How little do we realize what a vaginal examination means to them! It seems a trivial matter to us, but it is a dreadful experience for the patient. I am now attending a young woman who received such a nervous shock from such an examination that she has never recovered from it.

A case which made a strong impression on me in my student days and possibly led me to adopt such strong views on this subject was that of a highly educated governess, whose reduced circumstances compelled her to enter a hospital in which I was an interne. She was examined under ether and was found to have anteflexion with prolapsed ovaries. It was necessary to excise her unusually thick, rigid hymen preparatory to local treatment, which was conducted regularly two or three times a week for a couple of months. Each time that she was treated she returned to her room in such a nervous condition that she hardly recovered before she was obliged to go through the same experience again. It is needless to say that, so far from receiving any benefit from the local treatment, she left the hospital in a far worse general condition than before. The poor girl assured me that her experience seemed like a hideous nightmare. It seemed to her sensitive mind that she had suffered a shock to her moral, as well as to her physical being from which she could never recover. Death, she said, would have been preferable to the constant wounding of her delicacy.

Now, leaving what you may regard as the purely sentimental side of the question, let us look at it from a practical standpoint. Let us consider for a moment how much information can be obtained by examining a young girl at one's office. We assume that she has the familiar symptoms backache, leucorrhœa and so-called obstructive dysmenorrhœa, *i. e.*, colicky pains in the uterus immediately preceding the menstrual flow and relieved by the passage of clots. The natural inference is that she has anteflexion. We place her on her back on the table and proceed with the ordinary routine. The patient contracts her muscles rigidly and the finger is introduced only with the greatest difficulty and pain to the patient. The cervix is finally reached and the examiner, if experienced, recognizes the presence of the flexion the presence of which he had already suspected. He essays to practice the bimanual and at once finds how different the conditions are from those described in the books. The abdomen is like a board and every attempt at making deep pressure with the external hand is met by a spasmodical contraction of the recti, which baffles him. I am not describing an exceptional case, but such a one as we ordinarily encounter. Turning the patient on the side, it is now possible to insert the finger farther and thus to make out the position and probable size of the uterus, and under favorable circumstances, a prolapsed ovary. But the sensitiveness is so general and the patient is so distressed by pressure on the hymen, that it is impossible to locate exactly the seat of greatest pain. The smallest sized Simm's speculum is now introduced, not without great pain and resistance, and we catch a passing glimpse of the cervix. An attempt to pass a sound develops such a spasmodic contraction at the os internum that we are very apt to make an erroneous diagnosis of stenosis when no true stenosis exists. Now, is this a satisfactory examination, on the strength of which you would be willing to make a private diagnosis and perhaps recommend the performance of a serious operation?

When it comes to the question of regular treatment under these condi-

tions, I have never thought that I accomplished much. The possible effect of an occasional application of iodine and the introduction of one or two glycerin tampons being offset by the general disturbance of the nervous system incident to the manipulations.

To-morrow I expect to examine under ether with a colleague, a young lady whose symptoms clearly indicate local trouble, although the doctor has wisely tried general treatment, galvanism, etc., for several months with benefit before resorting to an examination. Since the symptoms are typical of the class in which some local trouble may be inferred, I mention them briefly: Constant backache, preventing much walking, profuse leucorrhœa, pain in the left ovarian region radiating down the thigh, dysmenorrhœa sufficient to keep the patient in bed for a day or two every month, with a flow too profuse for a young girl; added to these are well-marked reflex neuroses, strongly suggestive of ovarian disease. We expect to find an anteflexed uterus, possibly a prolapsed ovary, and shall be prepared to divulse and curette while the patient is under chloroform. Of the lesser degrees of pelvic trouble I have already spoken and you will pardon me for again insisting on the importance of recognizing the difference between the two.

These cases are very common in New York, occurring often among girls of sixteen to eighteen, attending the higher schools and colleges, anxious to keep up with their classes and to finish the course, straining every nerve in school and out, studying from an early morning hour until ten o'clock or later at night; continuing this every day, without rest even during the menstrual period. The bowels are always loaded with hard fæces, the girl has headache; when she feels badly she must still continue her tasks, she has no time for rest. To treat such a patient once or twice a week for backache, leucorrhœa, and dysmenorrhœa by applications to the cervix and tampons, would be as sensible as to treat her for heart or lung trouble, of the existence of which we only suspected. You would accomplish nothing. Her faulty habits of life, her neglect of the rules of hygiene entirely offset anything in the way of local treatment. I had such a patient from an intelligent family; her parents wished me to examine her, but I declined and lost the case. I told her parents that I thought the trouble was due to hard work at school, faulty habits, bad diet and dressing and to constipation; that I did not think the slight dysmenorrhœa, leucorrhœa, and backache of which she complained would be benefitted by local treatment. I wanted them to take her out of school entirely, and to put her on selected diet, tonics, and electricity. She was quite anæmic. They were not satisfied to give this a fair trial and I next heard of her going to a lady physician, who had been treating her three times a week for three months for anteflexion. Now, I do not believe that the girl had pathological anteflexion at all. The best proof of it was that she was cured without operation and became pregnant within a month after she was married, and that the marriage occurred shortly after she suspended treatment. Now, these are just the cases which an unscrupulous man may make a good deal of money out of; but, happily, to make money is not the only object of the practice of medicine. The first object is to try to benefit the patient, and you certainly will not do that, but may do a great deal of harm, by immediately starting upon a course of local treatment in young unmarried women.

What will take the place of local treatment? You always have electricity to fall back on. It need not be employed within the vagina nor is it necessary to have all the expensive apparatus described in the books. A milliampére-meter, for instance, can be dispensed with. When observing Apostoli at work I noticed that he paid quite as much attention to the sensations of the patient as to his milliampére meter. In applying the galvanic current, then, you will practically come to give more heed to the sensations of the patient and the after effects of the application than to the exact dosage. The class of cases under consideration are much relieved by placing one electrode over the sacrum and the other over the ovarian region, passing a current of moderate intensity, just sufficiently strong to cause a warm, burning sensation. This simple treatment repeated twice or three times a week often produces a remarkably beneficial effect. I am unable to say just how the effect is brought about. There have been a good many learned explanations of

the action of electricity on the pelvic organs, but they are like many other theories in medicine, they seem to be only as a matter of fact electricity does remove pain in those cases in which there is no serious organic change. Dysmenorrhœa is often entirely relieved. But you must tell the patient in advance that it will be necessary to give it a fair trial, and not to expect marvelous results from one or two applications.

I find that general practitioners often fail to recognize clearly the indications for the use of the different currents, made clear to your mind if you remember that the galvanic current is in general sedative, the faradic stimulating. If you want sedation (as in ovarian pain), apply the galvanic current. If there is non-development, amenorrhœa, a small infantile uterus or subinvolution you want stimulation, which is obtained by the frequently repeated shocks of the faradic current: In such a case put one pole over the sacrum and the other on the abdomen over the fundus uteri. If you make intra-vaginal application place one electrode against (or within) the cervix, the other on the abdomen over the fundus.

Regarding general treatment, iron is usually indicated, and I often use manganese. There is a preparation called the pepto-manganate of iron which acts well. I regulate the bowels with a mild laxative, usually cascara. The patients should bathe regularly. They may take a cold sprinkle, followed by a good rubbing. Regarding vaginal douches, I would refrain from using them as long as possible in the case of young girls. It is unfortunate to have them begin to tinker with themselves, unless it be necessary for a profuse leucorrhœa, which will not stop after general measures have been tried. When indicated, the mother can instruct the patient how to use the douche.

The proper regulation of the bowels is important. It is not sufficient to simply prescribe a laxative. The large intestine should be thoroughly cleaned out. It is common for women to come to the clinic and say that their bowels move regularly and yet on investigation to find large fæcal masses in the rectum. These masses may press the cervix forward, and a prolapsed ovary may be constantly compressed by the distended rectum, causing much pain and aggravation of the trouble. The rectum should, then, be emptied every day, not alone to obviate mechanical pressure, but also pelvic congestion.

It is important to have the patient rest during the menstrual period. Mothers generally seem to be strangely indifferent to the sexual hygiene of their daughters. Some mothers will come to the physician and complain that their daughters will not remain quiet during the periods ; that they go to parties, to dances, skating, coasting, and one young woman told me that she went bathing during a menstrual period. It shows either gross carelessness or dense ignorance on the part of mothers to allow their daughters to so flagrantly violate health laws. I do not think that a woamn is fit to bring up a girl if she is not sufficiently well informed to instruct her about the ordinary principles of physiology. Many of the things which girls do during the menstrual period invite attacks of peritonitis. Every woman should keep quiet the first day of the period, and lie on the sofa or bed.

These simple rules fragmentary as they are, I think, will in the majority of cases do away with the necessity for an examination of young girls. I feel very strongly upon the subject, for I think it is a very important one. In the routine of a clinic, physicians are apt to have girls who may come for the first time, put on the table, and submitted to an examination without stopping to think of the consequences. There is something more to take into consideration than the mere question of a diagnosis. In the late Professor Flint's classical work it is stated in an introductory chapter that the first thing which the doctor should look to is that his medicine shall do his patients no harm ; next, that it does them some good. That applies to all therapeutics local and general. Stop and consider whether what you are about to do will in any wise injure the patient mentally or physically, and then whether it will do her any good. With that idea in mind, I advise you to put off an examination in girls as long as you can consistent with the symptoms. If the symptoms are such that you feel it is not doing her justice, that it is not scientific to longer defer it then make the examination under an anæsthetic. The patient will rarely object it, and the parents will not if the situation is properly explained.

COMMUNICATIONS.

PNEUMONIA AND ITS TREATMENT.*

By HIRAM CORSON, M. D.
PLYMOUTH MEETING, PA.

What is pneumonia? That question correctly answered, we will be prepared to treat it. Professor George B. Wood, of the University of Pennsylvania, one of the most accurate describers of disease and a practitioner of great eminence, to whose graphic descriptions of disease many of you have listened, says in his *Practice of Medicine*, that, "pneumonia has three stages, and is universally applied to inflammation of the lungs. In the first stage the lungs are merely engorged with blood, and the air-cells filled with a sero-mucous, somewhat bloody effusion. In the second stage a plastic extravasation has taken place, and the cells are filled with more or less concrete and bloody lymph. In the third stage the place of the plastic secretion has been supplied by a purulent fluid." Dr. Wood was a truthful man, had great opportunities in the Philadelphia Hospital to see the condition of the lungs in the different stages described by him, for they may all be present in a lung at the same time, when the disease continues to embrace fresh portions of it. In that I doubt not he is correct. But as the subject which now engages our attention is one of great importance, I beg you to bear with me while I quote from another author. Dr. G. R. Martine, of Glens Falls, N. Y., in a paper read before the American Medical Association in June, 1889, published in its journal September, 1889—a paper remarkable for its accurate description of the disease as it exists in cases involving much of the lung, and for erroneous deductions in relation to treatment—thus speaks:

"The first abnormal symptoms, after the premonitory chill, are the quickening of the pulse and the subsequent increased flow of arterial blood. Now, if we could take a microscopic view of the minute arterial ramifications in the lung structure, we would discern a distention in the caliber of the air-vessels in order to accommodate the augmented flow of blood; and if we would glance at the veins we would observe the plasma layer rapidly filling with white corpuscles, and the walls of the veins, irritated by the friction of increased circulation, would exhibit, here and there, white corpuscles adhering to their tenacious sides and finally penetrating their walls. A glance at the capillaries would show not only the white, but also the red corpuscles forcing their way through the overstrained capillary walls until the surroundings become engorged by their extravasation, and hepatization has commenced." Now, if we bear in mind the condition of the lungs as described by the writers, we must believe that pneumonia is first a congestion, then an inflammation, and if that be not arrested suppuration takes place. Dr. Wood says: "It has been doubted whether a cure is ever effected in this last stage."

We are now brought face to face with the disease. Is there anything we can do to remove the congestion? The patient has been sick less than twenty-four hours, he is not yet expectorating bloody sputa, and many of the opponents to blood-letting say this disease cannot be aborted; that, like measles, it has a course to run, despite all interferences; that it is a constitutional disease, and that if we can prevent the congestion from being too suffocative, the inflammation from involving too much of the lung, we may let it run its course. The members of our profession are divided into two classes: those who believe that the disease may be aborted, *i. e.*, arrested in the congestive stage if early called, and in the stage of inflammation before suppuration has taken place; and the much more numerous class, who believe that it cannot be aborted; that a case, even if it be in its incipiency, must go on—should be watched by the physician, and shorn of its power to take life, but be allowed to go on until a crisis is reached after a positively fixed number of days. Physicians of the first class aim to relieve the overloaded and suffering lung by the abstraction of blood, by means of the lancet, from the veins of the arm; and those of the second class, who boast that they "never bleed" in any disease, depend on giving relief by reducing the increased action of the heart with medicines which have that effect. But the members of this latter class are greatly divided in opinion as to

*Read before the Philadelphia County Medical Society, April 13, 1892.

the proper medicine to be used to hold the heart in check; what one regards as being very useful and safe, another considers dangerous—more dangerous than the disease, and withal inefficient—yet all speak from experience, each one with his remedy. Experience is a harmful thing, as a reason for continuing to practice a certain course, unless it has been successful experience. It reminds me of a case: I had attended a woman in her confinement, and, as she expected to have the child raised by hand, as the phrase goes, and had read my paper on "Food for Infants," so, when she appeared, I said: "Nurse, do you know how to feed a child so as to rear it without the mother's milk?" Oh, yes! I have had experience in doing that; my sister had three that I had to raise that way." "Well, how did they come on?" "Oh, very well; one of them lived until it was six months old." Who among us but can look back on measures which we practised, and which we believed indispensable because we had proved them, as we thought, by a long experience, but which we now see were not only useless but injurious. This, then, successful experience in the treatment of pneumonia is what we should follow. The absence of success, the fearful mortality attending the arterial sedative practice of the "no blood to spare" party; the immediate relief, the successful arrest of pneumonia by blood-letting, during a whole century, should cause the opponents to venesection to cease their abuse of those whose successful experience in the use of it has been testified to by some of the most eminent men of this city and this country. A few weeks ago I was told by a gentleman holding a high State office, that a physican of whom he inquired concerning the recent death of a prominent man, replied: "Oh! he was murdered by blood-letting." Does this man, who speaks so boldly about a measure of relief of which he knows nothing from actual experience, who never used the lancet in his lifetime, denounce Prof. George B. Wood, Physic, Parrish and the elder Hartshorne, Chapman, Samuel George Morton, Ezra Michener, Prof. Henry H. Smith, the Atlees—John and Washington—Traill Green, Henry Hartshorne, Jackson of Northumberland, N. S. Davis, Prof. S. D. Gross, and hundreds of others who could be named, as conscientious as himself and far more truthful? We have borne this stereotyped abuse long enough. Look at the terror spread over the country now, when these numerous deaths of the best of our people are every day announced, though all were in the hands of practitioners skilled in arterial sedation. Let us now see what the opponents of blood-letting resort to, to save the sufferers from death in this disease. From what I have learned of the present teachings in our colleges, and by conversations with practitioners, the main object is "to keep down the pulse"—that is the phrase. To do this, the most approved medicine is the fluid extract of veratrum viride.

"The object aimed at," says Dr. Martine, "is to hold the pulse below eighty;" and adds, "*that* is not only what should be done, but what *must* be done to save life." I know full well *that* is not necessary. Scores of times, after I have bled freely, with great relief to the patient and arrest of the disease, the heart, though tamed by the bleeding, continued its pulsations at from 80 to 100 per minute, or sometimes even more for two or three days, and yet the convalescence went on. Again, he says: "With what remedies do I hold the pulse at this point (below eighty)? and adds,, "veratrum viride seems to have served one best." To this, Dr. H. A. Hare, who was present at the reading, replied: "A great mistake is made in saying use cardiac sedatives in pneumonia, without recognizing the fact that they are to be used only in the first stage, before congestion has gone on to consolidation; the man who gives such drugs at the middle or end of an attack of pneumonia, might as well stab his patient. Digitalis is to be used at such times." It therefore appears that it is only in the congestive stage that veratrum is to be used. If this be true—and doubtless it is based on experience—how many patients have been sent to their graves by this much-used medicine! for well do we all know that it is the most used of all the arterial sedatives to keep down the pulse. And even Dr. Martine has peremptorily declared that it must be kept down, and that veratrum viride seems to have served him best. But it is not only Dr. Martine who disregards the stage of the disease, and uses it in all stages if the pulse is above eighty. I have long believed that nearly all the cases of pneumo-

nia which terminated in death within four days, and I know several such were hurried there by this patent and dangerous drug. Dr. I. E. Atkinson, of Baltimore, followed Dr. Hare, and said that "the use of veratria in the treatment was new; it had been several years under trial, and had not received general acceptance." If Dr. Hare's utterance be true, then veratrum viride can scarcely be used at all without killing the patient, for a physician is seldom called until the congestion has passed into the second stage, when, according to Dr. Hare you might as well stab the patient as to give it. How unerring must be the diagnosis, in order that this medicine may be given without risking the life of the patient. I have inquired of many of the "no blood to spare" class and have rarely found two that have the same treatment. Those who use aconite are afraid to use veratria, while the latter regard aconite as being more dangerous and less efficient Those, too, who use digitalis are afraid of the two drugs just named, and those who give two drops every two hours denounce others who give large doses of it (10 to 20 drops, frequently repeated) as pursuing a most dangerous practice. Judging from the accusations made by themselves against each other, what safety is there to the patient? The answer comes in saddest tones from homes made desolate by dangerous arterial depressants. To the two classes of opponents to blood-letting spoken of, there are others which should have a passing notice: first, those who rely on the use of sulphate of quinine to keep down the pulse and to diminish the heat of the body. While quinine is, in malarial diseases, an unrivaled medicine and has done valuable service, it is useless, if not really most injurious, in the treatment of pneumonia and other inflammatory diseases. We should feel greatly indebted to Dr. Horatio C. Wood for the experiments which proved to him that even very large doses of that medicine cannot hold the temperature of the body at a low figure. There was so much stress laid on the importance of preventing heart failure, by keeping down the temperature by means of quinine above all other medicines, because of its tonic powers, that Dr. Ripley, the two Drs. Jacobi and three other physycians of New York City made careful and repeated experiments to determine the value of the drug in that respect, and demonstrated beyond cavil that it is never useful, and often greatly objectionable—really injurious—in the treatment of pneumonia. I have often felt exceedingly thankful to Dr. Wood and the New York doctors for their careful and effective labors in that direction, and greatly amazed that, in the face of the assertions that quinine is useless in pneumonia to effect the purpose for which it is used, some persons still persist in its use. Many lives have thus been lost. The second class of those who fraternize with the arterial sedative practitioners is composed of the whiskey or stimulant practitioners—the physicians who see typhoid and blood-poison symptoms in all diseases. I will spend but little time with them. They are belated people clothed in, and proud of, the cast-off garments of progressive physicians. Let us look calmly at this subject. Are there physicians here who can say that there are medicinal properties in whiskey or in brandy which, in either large or small doses, warrant us in trusting the life of a patient to their action? It is a serious thing to experiment with human life. No means but those which have proved successful in numerous cases should be used when our patients are struggling for breath, and death hovering over them. There is nothing more saddening to me in the sick-chamber than to see a physician forcing alcoholic drinks on the dying patients, and yet it has been done countless thousands of times, and now oftimes they are used in the very earliest stages of pneumonia. Dr. N. S. Davis does not believe them essential in any disease. If, then, arterial sedatives, quinine, and alcohol are not adapted to relieve the congestion and inflammation of the lung, which constitute pneumonia, is there any remedy for that now fatal disease? We know that there is, but not from an experience like that of the nurse already named, nor of another one, greatly experienced, of whom allow me to speak. I was called to a child, lying on the lap of a friend, "because she had had experience with such cases." I said, "The child seems very sick." "Yes," she replied, "it has summer complaint, and it will die." "How do you know it will die?" "Oh! I have had experience, I had ten of them with it." "All your own children? did they all die?" "Yes." "Did you have the same

doctor for them all?" "Yes." "Well, your experience is worth nothing." I treated the child, and, to her disgust, it was soon well. Her experience is a fair type of the experience of those physicians who go on with the same fatal treatment, lose one patient after another, and speak of "experience" in treating the disease.

But now a word about those who "murder" their patients by bleeding them. What are the objections urged against blood-letting? and by whom? The first objection is, "No one has any blood to spare." If this be true, then it embraces all other objections, and none need be named. This certainly means that in health as well as in disease, the loss of even a small quantity of blood would be injurious to the loser of it. It means more than that—means, as is boldly asserted, that it is a permanent injury to the body, the bad effect of which is seen in the permanently weakened system of the person. Thousands of facts disproving this, and which are daily before our eyes, count for nothing. One would suppose that if half a dozen, or even one, of the respectable, truthful men here should declare that he had often bled persons in various diseases with the greatest of benefit to them, nothing more would be needed to prove the falsity of the declaration, "No blood to spare"—a cry so senseless, so false, that no decent man should utter it.

The very first act of these objectors after the birth of a child, in cases attended by them, is deliberately to cut the cord and waste two ounces of blood that ought to have passed into the body of the child.* But there is another objection urged, viz., that even in the earliest stage of the disease under consideration, though some relief may be obtained, no blood should be taken, lest it should leave the patient too weak to resist the exhaustion of a later stage—leave him in a condition in which even whiskey and rich food would, though *pushed*, not be able to save him from death.

Is it, then, injurious to take blood from a pneumonic patient?

This is the cry and the charge of those who have never seen a patient bled, and yet who have known its safety and value to be testified to by some of the most eminent physicians who have ever lived in this century or preceding ones. In my last four papers, published in the *Medical and Surgical Reporter*, I have given a few cases reported by the Conshohocken doctors, which were bled freely, and were so successful that opposition to venesection should be silenced in those who read them. I will now speak of some seen by myself, and in doing so will present some views which I have long held:

On February 16, 1887, I was called to see a physician two days after an acute, serious attack of pneumonia. I found he was under treatment by one "who never bleeds in any disease." He was expectorating the bloody, "rust-colored, prune-juice" sputa, a quantity of it being in the basin; had great oppression and that peculiar sense of great weakness so constant an attendant in pneumonia when the obstruction to free breathing exists. I had to wait nearly three hours for the return of the physician, and when he did come he was opposed to bleeding, and refused to accede to it, but proposed that the patient choose whether or not he would be bled. The patient knew well our different modes of treatment, and promptly said, "I will be bled." I asked the doctor to remain, and, slipping another pillow under the sick man's head, I drew blood until I found the pulse yielding in *force* and knew that faintness was approaching. Withdrawing the pillow to lower the head, I closed the vein and took a seat. In about ten minutes I inquired, "How do you feel?" "I am much relieved; I think it will do me great good. This was at noon. Went again in the evening; he was pretty comfortable, breathed much more easily, and had not coughed up the least particle of blood or rusty sputum since the bleeding. The distended blood-vessels were relieved of their fulness, and "the slow exudation from the inflamed vessels" spoken of by Dr. Wood was no longer forced through their coats. Would one or twenty doses of arterial sedatives have produced that effect? Having bled my patient what next did I do? Nothing, but told him that I would see him in a few hours.

And here let me say that, in the case already alluded to, when I saw by the papers that he had been bled, I said, "In all human probability he will die! "Why?" was asked. "Because he was

* See Transactions of the Penna. State Med. Soc. for 1872, p. 154.

Timidly bled by one unused to venesection and fearful of it, and because the other depressing, arterial sedative treatment will follow it, and the patient will suffer from their poisonous, depressing effects.

To return to my case : When I saw the patient a few hours afterward I found him pretty comfortable. I directed one Dover's powder, to be repeated in the night, if need be, because of pain. Next day a mild diaphoretic was administered.

Two days after this a physician who, as a neighbor, had given much attention to his sick friend, asked me : How do you find your patient?" I said : "He is well ; he needs only a few days in bed to regain his strength." I left for home, and he went to the patient and said to him : "The Doctor told me just now that you are well. What was it that cured you? was it that blood that came from your arm?" He replied : "The blood did not come from my arm ; it came from here," laying his hand on the affected side. "I felt it going from here as it went into the basin." How strong this testimony, given by a physician who felt in his own person the relief obtained by venesection! How confirmatory, too, is this of the testimony of Dr. Gross, the elder, who, in a discussion, had in the State Medical Society illustrated the effect of venesection in this way : "Should a man have an inflammation of the conjunctiva, and capillary vessels be so injected that the blood was of a deep redness ; and then he, being in a sitting posture, should be bled largely, the blood would be drawn from the capillaries, and the redness disappear. Just so does it draw the blood away from the capillaries,, of the congested and inflamed lung." Veratum viride in doses large enough to keep the pulse below 80, would not produce the least relief to the distended capillaries.. Having bled the patient, if in a few hours there is not much relief, he may be bled again, if needful, and even more than once. But what of local measures? Do I approve of the poultice or the pads of cotton to envelop the chest? No. Two years ago, after my criticism of Dr. Wells's paper was published, an aged physician regretted that I had not spoken of the value of "the blister" over the affected part. The subject before me was only that of "Blood-letting : Its Value or Danger." It is the same now, but I may add here that the application of cloths dipped in ice-water is to the patient the most agreeable application that I have ever used.

Despite the great length of this paper, I beg of you to hear the utterances of one of our most eminent men to his students at his clinic in the University Hospital, and published in the February number of the *International Medical Magazine*, pp. 43-45. Dr. William Pepper stated to his pupils at the clinic, that "the man of twenty-eight years had been well until ten weeks before his admission to the ward, and had during that time been treated by several physicians. On admission, November 5th, his distress was extreme; he was unable to lie down or recline, and was obliged to remain constantly in a sitting position, but did not get relief from leaning forward." Then follows a long and interesting account of the illness and treatment; after which follows: "On November 7th, the third day of his stay in the hospital, the symptoms were alarming, with deep cyanosis, labored action of the heart, orthopnœa, and high fever, that I had him bled from the arm to the extent of twenty ounces. The good effect of this was immediate, and although cyanotic symptoms returned to some extent on the following day; a material improvement dated from the time of the venesection." Again the learned professor at great length gives his views of the case, and before closing his paper remarks, January 5th: "He has continued to do well. and is now thoroughly convalescent. Before closing, I would call your attention to the extraordinary effect which followed the abstraction of blood. All of us who saw his condition before the bleeding, and watched the immediate effect of this, were satisfied that his life was saved thereby. I doubt if any other remedy could have acted so promptly and efficiently. It was the observation of such striking results, when bleeding was used in suitable cases, that gradually led our medical forefathers to rely upon it more and more in grave crisis, until its occasional and legitimate use degenerated into almost promiscuous abuse. It is one of the tasks set before clinical medicine to-day to indicate with the greater precision, rendered possible by our improved methods of investigation and more full knowledge of natural history of disease, the exact conditions un-

der which this most powerful remedial measure is to be adopted."

Such are the recent utterances of the able editor of *A System of Medicine by American Authors*, in which is a paper by Alfred Loomis, M. D., Professor of Practice in the University of New York, who believes "pneumonia a constitutional disease, with a local manifestation," and regards blood-letting as a dangerous plan of treatment. Such, too, has been the views taught to large classes of students by Prof. Pepper until he made trial of the remedy. I sincerely hope that Prof. Loomis, too, will make a trial of it hereafter, and be induced, like Dr. Pepper, "to doubt that any other remedy could have acted so promptly and efficiently."

I cannot be too grateful to Prof. Pepper for his valuable testimony in relation to venesection, and for the hope which he has given us, that hereafter he will not withhold this potential means of relief from those suffering in the grasp of this (now) too fatal affection. It is one of the most remedial diseases when properly treated; but when managed by arterial sedatives and their aids, stimulants and excess of food, a most fatal one. More than sixty-five years of careful, anxious observation of the effects of blood-letting in pneumonia have proved to me that it has no rival as a remedy for that disease. —*For discussion, see Society Reports.*

ON DISEASE OF THE MASTOID PROCESS.*

By Dr. E. S. Clark,
SAN FRANCISCO, CAL.

I propose to present briefly, a general outline of the conditions, treatment and results of some cases of mastoid affection occurring in my practice the past year and a half and showing the advantage of an early operation. There were sixteen cases treated and of these I operated on fifteen, all resulting in recovery; the other (No. 4) refused an operation and died six days after I first saw him.

The following table will show at once the status, length of treatment, etc., of each case:

It will be seen from the above, that the average duration of middle ear affection before operation (except in the chronic forms) was about five weeks. In eleven of the fifteen cases operated, the discharge ceased after a few days. In one case only (11) does it still continue, and this is a chronic otorrhœa of twenty years standing. In all but four cases there was obtained communication with the middle ear, allowing me to cleanse the ear thoroughly by syringing through the fistula. This com-

†In these cases there was a relapse from a chronic otorrhœa.

munication closed in one to four days, in all but two cases (2 and 14). The external wound closed in from one to four months, except the first which remained open fifteen months, and the last two cases still under treatment. After recovery the memb. tymp. (except when destroyed by chronic otorrhœa) was always somewhat thickened, and the hearing from 0.10 to 0.50; very good considering the previous condition, which was in ten cases h. = 0.0.

In case 1, a second operation was necessary, to close the external wound. In case 2 the discharge from middle ear continued for four months, ceasing about the same time the external wound closed.

Affection of the bone resulted from chronic otorrhœa in two, from acute relapse of chronic otorrhœa in three, and from the acute form in the remaining eleven cases.

Case 14 a child of five years had scarlet fever, followed by bilateral otorrhœa; a swelling appeared on mastoid region of left side. This was opened by the attending physician, but the parents evidently neglected the child, for when brought to me, eight months later there was visible behind the left ear a large circular opening two ctm. in diameter, showing denuded bone, which proved to be a sequestrum of the entire mastoid process and adjacent osseous tissue. This after removal and thorough disinfecting resulted in a perfect cure in three months with hearing h. = 0.10 (bilateral) the memb. tymp. showing only a small perforation. In this case, both ears being affected, there was before the operation, almost total deafness, the child hearing only a loud voice; while at the close of treatment, she could hear on either side, ordinary conversation in six meters. Case 15 is interesting in that the patient, a physician, would take no anæsthetic, and the operation was made with no assistance except himself. There was no swelling of the mastoid region, nor the slightest pain on pressure, yet the necrosis was probably more extensive than in any of the other cases.

The method of operating followed by me is to use Schwartze's chisels until pus is reached (usually 1 to 10 m. m. in depth) then smooth out the cavity with scoops, syringe with solution of carbolic acid or sublimate, and iodoform dressing.

The treatment is to cleanse daily with disinfecting solutions and when the external wound is sufficiently closed to apply a conical lead nail, gradually reducing this in size until it is finally left out and in a few days the wound is closed and patient dismissed.

It may be stated here that in no instance has this operation resulted fatally, notwithstanding that two cases (2 and 8) were in a semi-delirious state when operated and could not possibly have survived a delay of twenty-four hours.

GUN-SHOT WOUND OF THE STOMACH—REPORT OF A CASE.*

By A. A. SMITH, M. D.,
HAWKINSVILLE, GA.

Through the courtesy of Dr. A. N. Peurifoy, who was the attending physician, I am permitted to make a report of this case.

On 28th day of February last Dr. Peurifoy was called to see a negro, who in a difficulty with another negro, had received a pistol shot said to be in the stomach.

On arriving and after making an examination, the doctor found that in the fight which had occurred two hours previous, his patient, a boy, eighteen years of age, had received a wound directly over the stomach. A casual examination with the eye alone was all that was necessary to show that the ball had penetrated the cavity of that organ. Not being satisfied, however, he made a careful and cautious examination with the probe and found that the ball had entered at a point about two inches below, and to the left of the tip of the ensiform cartilage of the sternum. The probe passed readily into the cavity of the stomach, and the doctor supposing that the ball had passed through and lodged in some other position of the body did not pursue the examination further. When first seen morphine was administered hypodermically to relieve pain which was severe at the time, also instructions were given to use cold applications to the wound together with such other general instructions as was thought best. On

*Read before the Georgia State Medical Association, April, 1892.

the following day the doctor returned expecting to find a well developed case of traumatic gastritis with peritonitis. In this however he was mistaken as the pulse was 80 and temperature normal and no indications of any inflammatory process, whatever. At this visit the cold applications to the wound with morphine to relieve pain should there be any was continued, also instructions were given that in the event the bowels should not act, that two cathartic pills be given. On the third visit, which was about 48 hours after the boy had received the shot, he ascertained that there had been two or more free evacuations from the bowels, and to his great surprise the ball had passed with one of these evacuations.

M. Anderson, on whose place the difficulty occurred and for whom the negroes were working at the time, was immediately called by the mother of the boy and shown the ball. The wound healed by first intention, and just one week from the date of the injury the boy returned to his work, which was that of laboring in a saw-mill.

This is an unusual case and can be accounted for only on the theory that the ball was spent when it entered the cavity of the stomach, and dropping became mixed with the food and passed out as as other foreign bodies, such as coppers, nickels, buttons, etc., which enter the stomach by the mouth. Another fact to be noted in connection with this case, is in reference to the particular point where the ball entered, which, as already stated, was below and to the left of the ensiform cartilage of the sternum. This would indicate that it penetrated at or near the cardiac orifice and there being none of the contents of the organ in contact with the walls at this particular point did not allow any escape of food, which, had there been any, would have been attended with fatal results.

There were no special features in the management of this case, in fact there could be nothing done except to relieve pain and await developments. I omitted to state in the beginning of this report that the pistol used was what is known as the old style Smith & Wesson revolver 32 calibre, and the distance the parties occupied was about ten spaces apart, also that I have the bullet with me which I will take pleasure in showing should any gentleman desire to see it.

SOCIETY REPORTS.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting, April 13, 1892.

Dr. Hiram Corson read a paper on

PNEUMONIA AND ITS TREATMENT. (SEE P. 765.)

DISCUSSION.

Dr. William Pepper: I think great praise is due to Dr. Corson for the faithful and able manner in which he has kept before the profession the importance of blood-letting in certain conditions of disease, and especially in pneumonia. While not prepared to admit its necessity as a remedy in all cases, I must state that I find myself confronted—not rarely—with a group of symptoms indicating oppression of the heart, and approaching cyanosis, which yield to prompt and moderate venesection as to no other remedy. So that with continued caution, but, on the whole, with increasing frequency and confidence, I find myself resorting to it.

Dr. James C. Wilson: We must all regret the absence of Dr. Corson to-night; we shall certainly in the discussion miss his firm convictions, his ready retort, his wit, and the results of his ripe experience in this matter, which for so long a time has been so near his heart. It is certainly most interesting to hear this paper, a continuance of a series of papers in which this determined, clear-headed man at the age of ninety years continues to uphold his position in regard to the treatment of pneumonia. In listening to the paper it has been impressed upon me that I am in neither of the camps referred to by Dr. Corson. I must indorse what has been said by Dr. Pepper in regard to venesection. We all recognize the occasional necessity for venesection in the early stages of croupous pneumonia. It often gives relief from urgent dyspnœa and pain, and sometimes even appears to save life. It cannot, however, be regarded as a specific treatment. It must be considered as symptomatic. I do not find myself in the camp of those who are prepared to adopt venesection as a routine treatment in pneumonia. On the contrary, I feel that my experience is opposed to this or any routine treatment.

I find myself equally out of place among those who rely upon the group of remedies known as arterial sedatives. I read from a paper* which embodies some views that I have expressed in regard to the treatment of pneumonia.

The paper speaks of various methods that have from time to time been largely employed and have gradually fallen out of use.

"In the same manner we condemn the treatment by tartar emetic in large doses, and with it is to be relegated to the limbo of discarded medicaments in pneumonia Trousseau's lauded *kermès*. The treatment by large doses of veratrum viride in the early stages, which still survives and finds in many quarters earnest advocates, is based upon the same antiphlogistic idea and has little to commend it. To add the depressing effect of a powerful drug to the pathological influences already depressing the heart is now recognized as increasing the danger of cardiac failure. In fact, if as our knowledge of croupous pneumonia indicates, many of the symptoms are due to a toxæmia, it were better to bleed the patient, if he is to be bled at all, into a basin than into his own vessels. To depress the heart by veratrum viride or aconite in the first stage, and to harass it by digitalis at a late period are among the vagaries of a therapeutics which takes pleasure in vaunting itself as rational. To give cardiac depressants in croupous pneumonia is always of doubtful expediency, and digitalis as a cardiac stimulant should be administered only in response to special indications. Of the latter drug Brunton says, 'It is of little use in pneumonia.'"

The difficulty of determining the value of treatment in pneumonia, it appears to me, lies in our inability to estimate the part played by treatment in the ultimate results in a large collection of cases.

"Croupous pneumonia occurs with great frequency in connection with other diseases. It is not uncommon during convalescence from acute infectious processes. Those who suffer from Bright's disease and from valvular and degenerative diseases of the heart and from organic diseases of the nervous system are especially prone to it. It not unfrequently occurs as the terminal condition in these affections and in other constitutional diseases, such as diabetes mellitus and pulmonary phthisis. Under these circumstances, it preserves, however, its own clinical and anatomical characters, and must be regarded, not as a mere complication of preëxisting pathological processes, to which it has no essential causal relation, but as an entirely independent intercurrent disease.

"When we consider the modification of pneumonia under the existing circumstances and in the different periods of life from childhood to old age, and in alcoholic subjects, we are impressed with the uselessness of attemps to show by statistics the value of different plans of treating the disease. No general percentage of mortality can be relied upon as indicating the efficacy of a treatment, unless they are on a large scale and in connection with a critical analysis of the condition of the patients. It is a question of the seed, which is probably always the same, and the soil, which is definitely modified. The only reliable test of the value of treatment is its effect upon the general course of the disease, a test which is much influenced by the personal equation of the observer. For this reason plans of treatment once in vogue, credited with surprising results in reducing the mortality of the disease, have failed to stand the test of time and have passed into disuse. And while the profession unites in striving after some specific treatment for other infectious diseases, the present drift of opinion in regard to croupous pneumonia seems by common consent to be in the direction of a vigilant expectancy with active treatment of symptoms as they arise.

"Whether we regard acute lobar pneumonia as a specific inflammation, or, in the language of the day, as an acute infectious febrile disease, of which the pulmonary lesions are merely a localization, we recognize in its causation three factors—a pathogenic bacterium, a predisposition, and an exciting cause—in other words, the seed, the soil, and the implantation. Nothing in the process is more obvious than its specific nature.

"Pneumonia cannot be regarded as a simple inflammation. This being the case, the antiphlogistic treatment of former times scarcely deserves discussion. Indiscriminate blood-letting as a routine treatment for a specific pathological process, the natural history of which shows it to

*The Medical News, December 20, 1890.

be self-limited and of comparatively short duration, is not in accordance with modern therapeutic principles. Still less are repeated venesections and bleeding *ad deliquium.*"

It seems to me that we are fighting over the old battles that were fought almost a century ago in regard to the antiphlogistic treatment of fevers. No one now regards typhus or enteric fevers as inflammatory diseases. No one regards scarlet fever as an inflammatory disease, yet we know that toward the close of the last century and in the early part of the present century, when fevers were considered to be varities of *the* fever, fever was considered to be a manifestation of inflammation, and not only was its treatment by venesection discussed, but it was pretty generally practiced. Almost all physicians of a generation later than that of our distinguished friend have come to regard pneumonia as a specific infectious process. Nobody now holds that a specific disease shall be treated by venesection. We have here to deal with a self-limited disease, a disease of short duration, and a disease which, in the majority of cases, tends toward recovery. To bleed as a routine measure is to add in a large number of the cases that come under our care the ill-borne effects of depletion to the debilitating influence of a specific inflammation attended with a depressing toxæmia. Therefore, it seems to me that it is scarcely worth while to oppose a plan of treatment based upon a conception of the pathology of the progress which is no longer tenable.

To bleed, however, for the relief of the dyspnœa, to bleed for the over-distended right heart, is not only clearly a duty in certain cases, but I believe that it is a duty which is often omitted to the disaster of the patient. I myself have had unfortunate results in the cases of pneumonia that I have bled. I have bled but few cases—they probably do not number more than four—and every case that I have bled I have lost. I have bled freely and without hesitation.

In the treatment of pneumonia we must pursue a plan of vigilant expectancy. I am opposed to the use of large doses of digitalis in the latter stages, during the period spoken of as that of red hepatization, after the exudate has undergone coagulation and has established in one lobe or in the whole lung a marked obstacle to the circulation. It seems to me that the use of digitalis under these circumstances throws work upon the heart which is unnecessary, and tends further to harass it. In regard to the expectant treatment, the whole history of the disease, viewed from a standpoint of its specific nature, seems fully to justify in the present state of our knowledge an armed expectancy ; a method of treatment in which, on the one hand, stimulation is not practised, and on the other hand, depletion is avoided, in which there is relief of the symptoms with a use of proper hygienic measures, and the disease is allowed to run its course just as we feel obliged to allow the other self-limited infectious diseases to run their course.

Dr. J. M. Anders : In the first place I think that Dr Hiram Corson is to be congratulated heartily upon the uniformly good results obtained from free bleedings, and, in the second place, he is especially to be admired for his courage in bleeding during these long years, indiscriminately, and without hesitation. Now there are a great many men, it is true, who are not in the same camp with Dr. Hiram Corson. The speaker who preceded me stated that he was not in favor of indiscriminate bleeding, and that he bled simply for subsidiary reasons and purposes. In that opinion I heartily concur. But, gentlemen, the results of bleeding, as practised by Dr. Hiram Corson, are certainly unparalleled for excellence; and, hence, it will not do to say that his cases got well in spite of treatment, on the one hand, nor to say that these cases would have gotten well without treatment, on the other hand. It, therefore, seems to me that we are put to the task of finding an explanation for the good results of repeated large bleedings in the hands of Dr. Hiram Corson.

I have myself bled but very few patients with pneumonia. About ten years ago I promised Dr. Hiram Corson that I would bleed my pneumonia patients, which promise I have kept only in part. Soon after that I met with a case of sthenic type in a male about forty years of age, with full, boundiug pulse, flushed face, high arterial tension, and marked nervous excitement. I withdrew about twenty ounces of blood. This seemed to quiet the heart, diminish arterial tension, and

allay the nervous excitement, and the patient made a rapid and good convalescence. Sometime afterward I met with another case in which I tried bleeding, but with a fatal termination. This case was not of purely sthenic type, nor was it one, strictly speaking, of asthenic type. It seemed to occupy a middle place. I withdrew about twenty ounces of blood and did not repeat the bleeding. Now, according to the remarks of Dr. Corson, I probably bled timidly. I saw a third case in which blood-letting was performed, in the wards of the Episcopal Hospital. This case in the hands of a colleague, and I agreed with him that bleeding might be of some service, although the patient was practically moribund when the procedure was resorted to, and it reached a fatal termination in a short time. The cause was one of sthenic type, with more or less congestion around the seat of consolidation, which evidently had been followed by œdema.

The chief reason—at least so it seems to me—why Dr. Hiram Corson's results have been so regularly favorable is the fact that patients living in the country and suffering with pneumonia, generally present the sthenic type of the disease, while, on the other hand, cases occuring in large cities like Philadelphia, very generally do not present the sthenic type, but rather the asthenic adynamic type. When a patient or the sthenic type presents himself, it seems to be far better to bleed than to give arterial sedatives—better than to give veratrum viride or tincture of aconite. The bleeding will most certainly quiet the heart's action, lower arterial tension, and allay more or less the nervous excitement, and will remove a portion of the burden from the heart without robbing it of much, if any, of its power. It is true that veratrum viride or tincture of aconite will also relax the bloodvessel walls, will also quiet the heart, but all of the indications fulfilled by these drugs, and I say it without hesitation, do so at the expense of heart power. The same is not true of blood-letting—at least, not to the same degree. Veratrum viride and tincture of aconite, while relaxing the vessel walls, also act as cardiac depressants.

I gather in the next place, that Dr. Hiram Corson has had good results from blood-letting in the second stage of the disease. It is hard to understand how bleeding at this stage can be of benefit, unless, as Dr. Wilson has explained, under certain circumstances, we thereby relieve an over-distended and dialated right heart. On the other hand, it is to be remembered that in the second stage of pneumonia, as in the first, the fibrin factors of the blood are three-or-four-fold what they are normally. Hence, under these circumstances, large bleedings, by diminishing this tendency, will lessen the liability to the formation of cardiac thrombi, and, to my mind, cardiac thrombi are frequently the chief cause of a fatal termination. At all events, thrombi are followed by dialated right heart, venous stasis, and death.

I do not believe that blood-letting exerts any good local effect in the second stage. The only way in which bleeding can affect favorably the lung is when we have such complications as congestion around the seat of consolidation, followed by œdema. Bleeding then acts according to ordinary hydraulic principles, and only in this way.

The method pursued by myself in the treatment of pneumonia is very briefly as follows, and in stating the method which I have pursued for a number of years, I shall perhaps bring out a few points bearing upon the paper of the evening. During the first stage of pneumonia, as I have already said I have bled a couple of times. My usual method, however, is to give morphine hypodermatically as recommended by Dr. Alfred Loomis, of New York. Perhaps the chief reason that I have not bled is because I have not met with a purely sthenic type of the disease. During the past winter I, however, saw two cases that apparently belonged to this type, but as they both followed la grippe, I was timid and did not bleed. Since they have died, I have regretted that I did not bleed them. I give morphine in doses of one-sixth to one-quarter of a grain repeated every eight or twelve hours. Morphine fulfills several indications fulfilled by blood-letting: it quiets the heart's action, it relieves pain, it guards the heart, and at the same time gives rest and comfort to the patient. In addition to morphine, or if it does not suffice to allay arterial tension, I use local blood-letting, applying several leeches and withdrawing six to eight ounces of blood, and repeating this if necessary. If leeches be not convenient, I sometimes resort to wet cups, withdrawing about the same amount of blood. It is hard to explain

the effect of local blood-letting on physiological grounds, yet of the efficacy of this method I am thoroughly convinced. It does diminish arterial tension and nervous excitement and gives relief from pain.

In the second stage of pneumonia the indications, so far as the local trouble is concerned, are, it seems to me, the reverse of what they are in the first stage. In the first stage, the bloodvessels are dilated, but in the second stage the bloodvessels are, as a rule, compressed. Their lumen is diminished. The obstruction to the pulmonary circulation is greater than in the first stage. In the second stage the indications are for the use of stimulants, but alcoholic stimulants should be supplemented by the administration of strychnine. Strychnine certainly fulfills certain indications not met by alcohol. Especially should we note its effect on the vasomotor and respiratory centers. If strychnine and alcohol fail to relieve the heart, then I resort to digitalis. I do believe that digitalis increases the capacity of the heart for work. Since it slows the heart's beat, it also allows time for the heart to carry on its nutritive functions. When the digitalis fails to whip up sufficiently the flagging heart, and venous stasis goes on increasing, then I administer oxygen by inhalation. During the last stage I use the stimulating expectorants, and where resolution is delayed nothing is better than turpentine.

I shall not take up the time any longer; but I wish to say, in conclusion, that the Society is indebted to Dr. Hiram Corson for having produced this paper, and for calling renewed attention to a measure which has been too much neglected in recent years.

Dr. H. C. Wood: I should not speak to-night did I not think that there was great danger that, in the lack of clear thinking, we were perhaps losing lives. I do not propose to do more than to make a few comments upon what has been said by my friends Dr. Wilson and Dr. Anders. I am always afraid of rhetoric in a scientific discussion. When I hear of such things as a heart being "harassed" by digitalis and similar expressions, I always begin to fear that the science is in inverse proportion to the rhetoric. Now, how can digitalis harass the heart? Much more, how can it exhaust the heart? You might as well talk of exhausting a starving man by a dish of broth, as to talk of exhausting a heart by giving digitalis. Digitalis adds power to the heart. That is an absolutely proven physiological fact. It lessens the nervous irritation of the heart, and at the same time increases the length of the diastole and the force of the systole; far from harassing the heart with digitalis, you quiet the heart that is already harassed by disease.

Then, again, we have heard that the heart is laboring with an obstruction, and therefore we must not give digitalis. That is the very reason why we must give digitalis. You have one-fourth of a pair of lungs obliterated—that means that one-fourth of the lumen of the vessels is shut off, so that the heart must force the normal amount of blood through three-fourths of the normal space. Of course, under such circumstances, the vessels and the right side of the heart must be oppressed. The heart is weakened by starvation and disease, and it finds itself in the presence of narrowed channels. Digitalis aids us in advanced pneumonia, because there is obstruction, and because the right side of the heart feels the power of the drug. We know by clinical experience the value of digitalis. Statistics are fallacious; but there is a kind of test that is not fallacious. If you take a man dying with a feeble, thready pulse, scarcely alive, and raise him up with digitalis and get the long, strong pulse, and then take away the digitalis and see him drop; give the digitalis again and lift him up again; then let him drop again and lift him up again, you have proof that the digitalis does control the circulation. You know that it does do good. Moreover, in advanced pneumonia, when properly used, digitalis has no power for evil. The real difficulty in its use in pneumonia is that, somehow, high temperature interferes with its action. When there is high temperature in pneumonia, the heart muscle often will not respond to digitalis.

Now a word to my friend Dr. Anders. He spoke in regard to blood-letting and arterial sedatives, and said that you take power out of the heart by arterial sedatives, but that you did not take power out of the heart by blood-letting. Let us make an experiment: give a man daily doses of veratrum viride and keep the pulse down for twenty days, and then take a man and remove twenty ounces of blood

each day for twenty days. Which heart would come up the strongest at the end of this time? It is essential, in the practice of medicine, to distinguish between depression and exhaustion. Blood-letting exhausts a man—it takes power out of a man. It leaves the man something less than before. Does veratrum viride take any power out of a man? It lays its hand upon the heart and vasomotor centers, and binds them down with strong thongs. The man is there, and when the thongs are cut—*i. e.*, the depression removed—he rises up as strong as ever.

Dr. C. McClelland: I should like to say one word from my personal experience. Something over two years ago I had an attack of pneumonia; both lungs were involved; the heart was depressed, dropping every third beat, and valvular murmurs were present. The mind was clear. I said to the physician in attendance: "This kind of thing cannot last more than twelve hours. Can nothing be done? How about digitalis?" He agreed to try digitalis. It was used vigorously and in such large doses that one of my attendants remained all night to watch the effect. Inside of eight hours the beat of the pulse was strong, the intermissions had practically ceased, and the valvular murmurs had disappeared. I believe that had it not been for digitalis I should not be here to tell the story.

Dr. Judson Daland: I have been quite interested in the treatment referred to, but I think that the ordinary cases of pneumonia—as we all see them in the majority of uncomplicated cases—may go on to a satisfactory result. I have been much impressed with the fact during the last two years. In the first place, as has been said by Dr. Anders, when death occurs it is usually directly through the right heart. We have an increase in the amount of blood in the venous system and over-distention of all the veins and dilatation of the right heart, with death following from failure of the right heart. Four autopsies made during the past year showed this condition very conclusively. It seems to me very certain that if we abstract blood directly from the median basilic vein we directly drain the blood from the right heart and lessen venous stasis and take off the labor from the right heart and prevent death from heart failure. This, I take it, is an important indication for blood-letting.

Furthermore, as has already been said, heart-clot is unquestionably accountable for many deaths. It has often been said that in pneumonia the blood has an increased tendency to coagulate. This fact has not been appreciated with sufficient clearness. About eight months ago I had occasion to examine the blood of several cases of pneumonia, and at the same time was examining blood from other diseases, chiefly diseases without fever, and I was strongly impressed by the fact that in every case of pneumonia, when I attempted to examine the blood it would coagulate in the capillary pipette with great rapidity, and it required special manipulation in order to make the examination. It seems to me that if the right heart and venous system is over-filled, a condition favoring the condition for this coagulation, I think that physical signs of dilatation of the right heart should be searched for, and that we should not wait until cyanosis develops. In two cases of pneumonia where the right side of the heart was dilated and the veins overfull, the physician insisted upon waiting for cyanosis. Cyanosis did develop, and at the same moment death occurred. I think that if the physical signs can be made out, and with it are associated symptoms, venesection should be promptly performed.

Dr. S. Solis-Cohen: I arise to call attention of the Society to the usefulness of the nitrites in the treatment of pneumonia. Some of the remarks in discussion, especially those of Dr. Wood, might at once have suggested to those familiar with the physiological properties of the nitrites the great power that this class of drugs can and does have in the treatment of diseases like pneumonia. I am not speaking of the management of conditions directly dependent upon the specific poison of the disease, if there be such a specific poison, but of what may be done to relieve the embarrassment of the circulation from mechanical stasis due to obstruction in the lungs. Dr. Wood laid stress upon the fact that a large portion of the arterial conduit was wiped out, or better, blocked out. It seems to me an obvious inference that it would be highly desirable to increase the capacity of the remaining portion. Looking on the arterial and venous channels, pulmonic and systemic, as one continuous canal, it is theoretically clear that we must especially dilate the arterial

portion in order that the whole volume of the blood may not accumulate on the venous side; and in order likewise to facilitate the passage of the blood through branches of the main canal collateral to those obstructed. The nitrites—nitro-glycerin, amyl nitrite, sodium nitrite—will dilate the peripheral arterioles, and will dilate the capillaries, increasing the capacity for blood of the arterial side of the circulation, and thus partially compensate for that portion of the arterial channel dammed out by the blocking of the vessels in the lungs. Pulmonic vessels are dilated as well as systemic, and thus the right heart is directly relieved of labor, and the danger of over-distention in large degree diminished. Respiration is likewise relieved, especially if oxygen be given by inhalation coincidently. I have seen this remarkably illustrated, not once or twice, but more than a dozen times within the last two or three years since my attention has been more particularly directed to the subject. This measure alone will not, of course, succeed in bringing about recovery in every case of pneumonia. There are other additional ends to be aimed at by the physician, and I had been hoping to hear attention called to one of them. The increased tendency of the blood to coagulation in cases of pneumonia was dwelt upon, but the value of ammonium salts in maintaining the fluidity of the blood was not spoken of. This subject is not at all new. It was long ago brought to the attention of the profession by the same great man that introduced nitrites, Dr. Benjamin Ward Richardson, of London. Others had, perhaps, used ammonium carbonate and ammonium chloride before him, but he it was who laid especial stress upon the danger threatening pneumonitic patients, of death from heart-clot, and for that reason urged the early and free use of preparations of ammonia to prevent heart-clot by maintaining the fluidity of the blood. He has also called attention to a useful method of administering ammonia in septic conditions associated with fibrinous exudations, namely, by giving the vapor of ammoniated chloroform.

I should like to add one word in regard to the rationale of blood-letting in selected cases of pneumonia. I have seen blood-letting do good by relieving the right heart of distention, and by diminishing the quantity of blood which the enfeebled heart has to push through the much-diminished caliber of the vascular channel. There are two ways of taking a portion of its labor from the heart: one is to dilate the arterioles, thus increasing the vascular capacity and diminishing the vascular resistance—the agent used for this purpose being a nitrite—and the second is to diminish the quantity of blood which the heart is called upon to propel and the vessels to conduct. It has been said that the loss of twenty ounces of blood is a serious matter to the enfeebled patient. That depends on where the blood is, what its condition is, what it is doing. A portion of the patient is thrown out of functional relation, and a normal quantity of blood becomes relative plethora. It is of no good to the patient while it stagnates in his viens. It does not nourish him, and it does interfere with the passage of the nutrient fluid into the tissues. He is a great deal better off without these twenty ounces if he is unable to make use of them, if they contain toxic products, if they are simply blocking the lungs and veins, and finally blocking the arteries. They antagonize the heart—first the right heart, then both sides; they do no good; they are not, to use Dr. Wood's comparison, liquid food to nourish; they are liquid poison to kill, and the sooner the patient gets rid of them the better his chances for recovery.

Dr. A. E. Roussel: In connection with the use of digitalis, it may be interesting to note the results obtained by Professor Pétresco, reported in a recent number of the *Bulletin de Thérapeutique*. [See editorial in the Reporter of Dec. 12, 1891.] He gives an analysis of over seven hundred and fifty cases in which he used large doses of digitalis—as high as two drachms of the leaves in twenty-four hours—irrespective of the stage of the malady. The mortality was a trifle over one per cent. He claims that the pulse-beats are reduced from 120 or 130 to 28 or 30 per minute, and the temperature also seems to be favorably affected, falling four or five degrees; besides which, it is said that the entire course of the disease is jugulated in so short a time as three or four days. The publication of such a large series of cases seems to require a careful study of the matter. We have all been in the habit of giving digitalis in the second and third

stages of pneumonia, and this report would bear out the statement that digitalis and carbonate of ammonia are eminently satisfactory modes of treatment.

Dr. Ernest Laplace: I have been very much interested in the discussion, and was hoping that a few more words would be said on the etiology of the disease, so as to give some explanation as to the reason why there are sometimes sthenic cases and at other times asthenic cases, and therefore why bloodletting would be indicated in certain cases and not in others. We know, as was said by the first speaker, that pneumonia is a specific disease; that it needs a special soil and a special seed developing in it. We know that the same seed, developing in a different soil, will produce a disease, but that disease is not necessarily the same in every respect. In the same way we plant a seed in different countries, and it will not produce exactly the same tree in each case. There are as many different soils as there are patients suffering from the disease. As a result of the growth of the peculiar organism we have produced a toxalbumin, or, if you will, ptomaine, which in the patient acts as a heart stimulant, and we have a sthenic case. In such a case gentle bloodletting will relieve the heart of the extra amount of work. It will not cure the disease, and has no tendency to alter it, but makes it less grave than when the blood has not been removed. Where the toxalbumin is not so violent, or is not so abundant, or is of a different physiological action, the heart not being over-stimulated, the disease weakens the patient, and blood-letting is not indicated. In such a case calm expectancy, with readiness to meet the symptoms as they present themselves, is the proper plan of treatment.

Dr. Frank Woodbury: I have been much interested in the discussion, but of course, was particularly attracted, as doubtless many others were, by the paper of Dr. Hiram Corson. The experience of a physician extending over a period of sixty-five years is certainly one that we should receive with great respect, and especially when he possesses the recognized ability as a practitioner such as that possessed by the author of the paper under discussion. While listening to the paper and the discussion, the celebrated advice of Chomel came into my mind, "to treat the patient and not the disease." We have been considering some of the dangers attending a case of pneumonia. The greatest danger to which the pneumonia patient is exposed, in my judgment is to have a man for his physician who is so engrossed with treating the mental abstraction which he calls pneumonia that he connot see the concrete needs of the actual individual patient who claims his care. I entirely agree with the last speaker with regard to the desirability of confining ourselves to the scientific language in a discussion of scientific questions, and the dangers to which we are liable from the abuse of rhetoric when referring to medical subjects. I wish to use only words of truth and soberness, and therefore, will not speak of the heart "putting its shoulder to the wheel" under the influence of a remedy, nor as "harassed" either by a drug or a disease. Being rather deficient in poetic insight or the imaginative faculty, I will even confess that I could never see any "indication" for remedies. The word "indication" is not in my therapeutic vocabulary. Nature never "indicates" to me a drug or a combination of drugs in any morbid state. Experience has shown that patients may be benefited by certain remedies when judiciously administered, but we are not restricted to such drugs, and we are willing to abandon them as soon as others shall be discovered which will cure more "safely, quickly, and agreeably." This we could not do if Nature infallibly indicated remedies. The late Dr. J. Milner Fothergill called attention to the robust countryman at Smithfield and compared him with the pallid clerks and artisans thronging the London streets, and very justly pointed the moral that the line of treatment in these two classes in case of disease must be entirely different. Perhaps this will explain the success of Dr. Corson in a rural community, with his practice of depletion in pneumonia, a practice which our city physicians have been obliged universally to abandon. In spite of the advocacy of the great Dr. Rush and his successors, it has almost become obsolete with us. I think that perhaps we have done as much as we should do for the present, in regard to the classification of diseases, and that we should now begin to classify our patients as the foundation of success in therapeutics. For instance, instead of dividing pneumonia into

sthenic and asthenic cases, I think that it would greatly simplify the problem of treatment if we were to substitute the words plethoric and anæmic. It is easy to make a distinction between plethoric and anæmic patients. Sthenic cases are more likely to occur among the plethoric; asthenic cases among the anæmic. In plethoric cases, or even where the hyperæmia is local, blood-letting is a rational procedure, and when the symptoms are urgent and do not admit of delay, it is practised with advantage, as Dr. Corson has shown. We should not, however, bleed for the pneumonia; as has been already said, we should bleed for mechanical reasons. Where the symptoms are less urgent we may decide to depend upon arterial sedatives and dieting to accomplish the same purpose. In regard to a typical case of pnuemonia, by which I mean an ordinary acute lobar or croupous pneumonia, I might say that I do not recognize congestion as the first stage in the morbid process. Even the premonitory hyperæmia of Stokes must have something to precede it. It is certainly permissible to assume a nervous disturbance, which causes the local hyperæmia; in other words, since efficient morbid influence acting through the vasomotor nerves of the affected lung and the cardiac ganglia, and causing tophic disturbances. The view is now generally held that pneumonia is not an inflammation, but a general disease, if not a "specific fever."

In a plethoric case, or robust patient, I should commence the treatment by that old-fashioned remedy, an emetic, and preferably ipecacuanha, because it is a fact that this emetic tends to produce anæmia of the lung. There is no better arterial sedative than an emetic, and this also quickens the functions of the skin and favors diaphoresis. This I would follow by magnesia sulphate in sufficient doses to produce several watery evacuations of the bowels. In this way, we relieve the overdistension of the blood-vessels. We do not bleed the patient into his own tissues, but into his own bowels. Then I should simply give remedies to make the patient comfortable, and keep him upon a very restricted diet. If there is great restlessness or too much cough I would give small doses of chloral or bromide in preference to morphine. I remember a case where a patient was doing well under small doses of chloral and bromide, I was attending him during the absence from the city of another practitioner who, on returning, took charge of the case and changed the treatment to Dover's powder, with the result that in the course of a couple of days, the patient died. I think that many deaths in pneumonia are really due to opiates, and, in the beginning, they are inadmissable, just as in the early stages of bronchitis.

An anæmic case of pneumonia I should treat entirely differently. Here I should give restoratives and broths, and depend upon nursing more than upon medicines. I would give digitalis and quinine, and perhaps iron, but in such cases supporting the strength of the patient is far more important than any special drug, and bleeding is not to be considered.

As we know that a large majority of the cases of pneumonia get well under any and every form of treatment, we are tempted to echo the advice of Chambers with regard to rheumatism, "to cover up the patient with blankets and leave him alone," which, in fact, is about what Jürgensen advises in pneumonia. Unless we have certain symptoms that give annoyance, pain, or suffering, I think that the vigilant expectant treatment advocated by Dr. J. C. Wilson in opening this discussion, not too actively interfering with the course of the disease, will give the best results in the greatest number of cases. Where the emergency arises and the patient is suffering from acute plethora, or distension of the right heart, or overwhelming congestion of the lung, I should bleed just as if the patient did not have the pneumonia, but I would never bleed for pneumonia. The routine practise of venesection in this disease has never recovered from the death-blow it received at the hands of J. Hughes Bennett. At the same time, I can understand that the emergency may sometimes arise when the abstraction of a certain amount of blood will afford great immediate relief to the patient, without being followed by any serious consequences as regards the subsequent course of the disease.

Dr. John B. Roberts: It may seem presumptuous for me, who see comparatively few medical cases, to speak on this subject. I have, however, bled in a few cases of pneumonia. I now recall four cases, of which three recovered and one

died. It is, however, not fair to the Society nor to statistics to quote these cases together. They are divided into two distinct classes. The first class contains cases of traumatic pneumonia, which I see in surgical practice. They are usually of the sthenic character, and in them at times the engorgement of the lungs, from acute traumatic pneumonia, demands depletion. The second class of cases in which I am inclined to bleed are cases similar to those spoken of by Dr. Anders, in which, in addition to a pneumonia, there is overwhelming of both lungs with what might be called œdema of the lungs. These are cases in which the presence of moist râles indicate that the smaller bronchial tubes, and possibly the vesicles where they are not filled with the croupous deposit, are filled with mucous or serous fluid, thus preventing respiration. The patient is cyanosed, gasping for breath, and *in articulo mortis*. These cases should be bled. I have bled two of them and one has recovered. The other two cases of my four already mentioned, were instances of traumatic pneumonia in which I think that there is no question that a moderate bleeding of from eight to ten ounces or less (I have never removed many ounces) was of service. One was a case of gunshot wound of the lung followed in about twenty-four hours with violent dyspnœa, orthopnœa, and all the symptoms of acute pneumonia. I at once bled and he was relieved; the symptoms disappeared and he rapidly recovered, notwithstanding the fact that he had a bullet in the chest. The second case was that of a man who had been run over by a wagon, had several ribs broken, a pneumonia following from punctured wound of the lungs by the ribs. He was bled, with a satisfactory result. Of course, we must separate these cases into two groups—those of traumatic sthenic pneumonia, and those in which there is overwhelming of the lungs and the patient threatened with drowning in his own secretions. In the latter case the abstraction of blood gives the lungs an opportunity to be relieved, lessens the engorgement of the right heart, and permits respiration to be properly carried on.

Dr. George N. Highly: I have listened with a great deal of pleasure to the remarks that have been made, and I feel very thankful for the favorable comments which this paper has elicited. With regard to pneumonia being a general disease, we differ from the many eminent men who hold that view. We do not think that this has been proven. Because it is accompanied by certain constitutional disturbances, is no reason for regarding it as a specific disease. We know that local troubles when similarly situated pursue like courses, and when extensive are accompanied by constitutional symptoms in proportion to their extent and gravity. But whether we regard pneumonia as a local disease or as a local manifestation of a general disease, we must agree that the condition present demands relief by measures which will unload the lung and the right side of the heart, and we think that venesection does this with the greatest amount of relief and the least amount of depression. A word in regard to bleeding in the so-called asthenic cases. Out in Conshohocken we do not see such cases. We regard the condition as precisely the same in all our patients, whether robust or weak, or run down by disease. I know of one case, a woman with an ovarian tumor weighing sixty pounds, for which she had been refused operation. She was taken with pneumonia and her physician attended her for a few days; the disease had progressed to the second, and perhaps to the beginning of the third stage. Dr. Corson was called in consultation and advised venesection, which her attending physician had hesitated to perform on account of her great weakness. Twelve ounces of blood were removed with relief of the symptoms, and from that time she did not expectorate any more of the rusty colored sputa. That was a remarkable case and I could give the full notes if there were time. I refer you also to the case of Dr. Michener (*Med. and Surg. Rep.*, July, 1882), who, at the advanced age of eighty-seven years, and while suffering from a fracture of the arm, was attacked with pneumonia. He directed the attending doctor to "bleed until the pulse gives way and the respirations become easy without regard to what may be in the basin." This was done and relief soon followed. The amount taken was ℥xv.

About bleeding in the third stage. Dr. Corson's idea is that there is always some stage of congestion in part of the lung. If you could conclusively show that the area first affected did not extend with each succeeding day, and that the parts in-

volved simply went through the several stages without further extension, then it would be true that venesection would be harmful after the first or second stage. We think, however, that in every case and in every stage of the disease, until the crisis has been passed, new portions of the lungs are continually being involved, and for these new areas of congestion and inflammation blood-letting is of value.

SELECTED FORMULÆ.

PROPHYLAXIS AND TREATMENT OF SORE THROAT.

The following is recommended by Capart (*Nouveaux Remedes*):

(*a*). *Prophylaxis.*

℞ Crystallised phenic acid.....5 grammes.
Absolute alcohol .....10 "
Essence of peppermint.....10 drops.
M. Sig. Place 10 drops in a cup of hot water and employ it as a gargle night and morning.

(*b*). *Treatment.*

℞ 1. Decoction of willow..15 to 200 grammes.
Salicylate of sodium. 2 to 5 "
Biborate of sodium... 5 grammes.
M. Sig.—For internal use.

℞ 2. Calcined silica..... 1 gramme.
Alcohol,
Glycerine.....,. āā 10 grammes.
Water.....200 "
M. Sig.—For gargles.

—*Journal de Medecine de Paris*, March 27, 1892.

FOR STRIDULOUS LARYNGITIS.

In the treatment of this affection, the following is highly recommended:

℞ Chloroform.....5 to 10 drops.
Water.....25 grammes.
Glycerine..... 5 "
M. Sig.—A dessertspoonful every half-hour.

—*Journal de Medecine de Paris*, March 27, 1892.

FOR MARGINAL EXFOLIATIVE GLOSSITIS.

Besnier recommends the following combination:

℞ Cocaine.....0.05 gramme.
Balsam of Peru,
Boric acid..... āā 1.00 "
Vaseline.....40 grammes.
M. Sig.—Apply externally.

—*Revue de Laryngologie, d'Otologie et de Rhin.*, April 1, 1892.

HYPERIDROSIS.

℞ Sodii borat.,
Acid. salicyl.. .....āā grams 7.5
Acid. borici..... " 2.
Glycerin.,
Alcohol.....āā " 30.
M. ft. linim. Apply to hands thrice daily.

SYRUP FOR CHILDREN.

In the treatment of diseases of children the following is recommended:

℞ Creasote..... 5 grammes.
Alcohol, 90 per cent.....125 "
Glycerine ..... 50 "
Syrup of tolu .....250 "
Laurel water,
Distilled water.....āā 40 "
M. Each dessertspoonful contains five centigrammes of creasote.

—*Journal de Chirurg. et Therap.*, No. 11, 1891.

A NEW DIURETIC REMEDY.

Pichi (*Fabiana imbricata*) a new diuretic, and which also has a sedative action upon the vesical and urethral mucous membrane, is recommended in the following formula:

℞ Fluid extract of pichi..32 grammes.
Nitrate of potassium... 4 "
Distilled water.....90 "
M. Sig.—A dessertspoonful every three hours.

—*La Medecine Moderne*, April 7, 1892.

INFANTILE DIARRHŒA.

For thin, greenish, slimy stools, Dr. Meigs orders:

℞ Acidi sulphurici dil.....gtt. xij.
Morphinæ sulph.....gr. ¼.
Spir. vini gallici.....℥ ss.
Syr. zingib.....℥ ss.
Aquæ.....q. s. ad ℥ iij.
M, Sig.—One drachm every three hours.

EXPECTORANT.

℞ Ammonii et potass. tart.....gr. i.
Ammonii muriat.....℥ iv.
Ext. glycyrrhizæ.....℥ i.
Morphinæ muriat.....gr. i.
Syr. tolutan.....℥ i.
Ag. laur. cerasi.....℥ j.
M. Sig.—Teaspoonful every two or three hours.

—*Bartholow.*

SORE THROAT.

A gargle of hot claret often affords much relief in cases of acute catarrhal pharyngitis. Where the inflammation is rheumatic in character, a spray of the following is useful:

℞ Morphinæ.....gr. iv.
Ac. carbolici,
Ac. tannici.....āā ʒ ss.
Glycerini,
Aquæ dest.....āā ℥ iv.
M. Sig.—Use as a spray in the throat, about a teaspoonful at a time.

—*Med. Record.*

HERPES PRÆPUTIALIS.

A dusting powder employed by Besnier is:

℞ Acid. tannic. pulv.....grams 5.
Bismuth. subnitr.....gram 1.
Amyli..... grams 100.

THE

MEDICAL and SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO

P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.

(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:

29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:

Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates).... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt "**The Medical and Surgical Reporter**" and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

☞Please accompany orders with the money, and address all communications to

LEADING ARTICLES.

THE PREVENTION OF BLINDNESS FROM CONTAGIOUS OPHTHALMIA.

Many of the causes of blindness are operative chiefly or wholly in middle or advanced age, when perhaps the greater part or whole of the active working life has been passed in the possession of normal visual power, or at least after visual impressions have played their full part in the mental development of the individual. Blindness from birth or from childhood is a very much more serious matter, since it deprives the individual of a most important group of powers by hindering their development, and impoverishes the community by crippling one of its possible workers throughout the whole of his productive life.

Statistics indicate that of all cases about twenty to thirty per cent. are due to contagious inflammations of the conjunctiva, and in a large proportion of these the blindness is produced in early infancy or childhood. The contagious ophthalmias that cause blindness may be classified into two groups: ophthalmia neonatorum, which causes blindness solely in the first few weeks of life; and trachoma, which in this locality is seen mainly among the inmates of orphan schools and asylums, or where children are crowded together in tenement houses. Blindness from these causes comes through disease of the cornea leading to its opacity, and is generally quite irremediable; so that the hope of diminishing it lies almost entirely in the direction of prevention. In this case prevention may be accomplished either by the prevention of the diseases which cause the blindness or by management of them in such a way that blindness shall not result.

In these days when disease-producing germs, the isolation of cases, and the methods of disinfectant treatment claim

so large a share of professional attention, ophthalmologists have taken a renewed interest in ophthalmias, the chronic forms of which had been regarded as the most tedious, laborious and unsatisfactory conditions with which they had to deal.

With regard to causative germs, ophthalmological bacteriologists have contributed comparatively little to the general fund of positive knowledge. A few who have undertaken systematically to search for bacteria have established the presence of the gonococcus in ophthalmia neonatorum. Andrews found this germ in all of 122 cases he examined. More than one form of bacteria has been described as the essential pathogenic organism connected with trachoma. But investigations of this sort have thus far not excited much interest among ophthalmic specialists, and have lead to no radical change in the methods of treatment. Probably, however, few, if any, doubt the existence of such specific organisms, or that their implantation is a necessary factor in the production of these diseases. And this faith in the essentially contagious nature of these affections has led to an active effort to prevent blindness from them by stamping out epidemics through the isolation of cases, and by more efficient disinfectant treatment.

For preventing the spread of trachoma isolation is entirely practicable, since for this purpose isolation means little more than such cleanliness and care of the toilet as well-to-do cleanly people always practise for their personal comfort.

Trachoma is almost confined to the comparatively poor and degraded, and among them it seems to spread seriously only when especially favored by the crowding together of particularly susceptible and infected subjects. In Philadelphia the great majority of cases are directly traceable to infection during a steerage passage from some European country, or to crowded orphan schools or asylums, and a few cases arise in the overcrowded tenements of the lowest class. It is probable that the small number of cases of this disease presented in this city is due to the small amount of overcrowding—the small number of persons per house as compared with other large cities.

The important practical measures to be adopted then, are those directed to preventing the importation of cases infected in foreign countries or during the passage hither, and the prompt recognition, isolation and effective treatment of cases gaining admission to orphan schools and asylums. The first requirement is one of many that demand a better sanitary supervision of immigrants. The second is the proper attention on the part of managers of schools and asylums, which ought to be easily obtained, but by popular ignorance and indifference is often rendered difficult.

It needs to be reiterated and insisted upon that while the proper intelligent care of orphans is a most praise-worthy charity, the gathering them together to serve as a hot-bed from which to disseminate suffering and blindness is something quite different. It is to be hoped that the committee of the Medical Society of the State of Pennsylvania to look after this matter will be able to make some impression on the institutions of the State.

The opportunities for the transmission of trachoma are greatly increased by its extremely chronic course, and if, as is claimed, some of the methods recently introduced are capable of cutting it short, their application is of great importance in preventing the further spread of the disease.

The prevention of blindness from ophthalmia neonatorum is quite as much a question of treatment as of the prophylaxis. The principles and methods concerned are well-established, and have been clearly set forth in a paper by Dr. Schneideman in a recent number of the Re-

PORTER. The great obstacle to their efficient application is the failure to recognize the nature and gravity of the affection, on the part of those having the care of infants. Looking in this direction it is suggested that mid-wives be compelled, under liability of heavy fine for neglect, to promptly report every case of ocular inflammation to some health officer or responsible practitioner. It is probable that the adoption of such a law would at least bring the subject forcibly to the attention of many nurses and practitioners who at present do not recognize its importance. Even to agitate for its passage must have an excellent effect.

BOOK REVIEWS.

TRANSACTIONS OF THE AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNÆCOLOGISTS. Vol. IV. For 1891. Philadelphia: Wm. J. Dornan.

This volume of the Transactions of the American Association of Obstetricians and Gynæcologists contains some very instructive matter from prominent men in these specialties. The last meeting of this society was held in the Academy of Medicine in New York City, and was attended by 43 of the 83 members composing the body. Among the many good papers contained in the volume, we specially note the following: "A Clinical Note on Intrauterine Irrigation After Labor," by Lewis S. McMurtry, of Louisville. The subject is treated in a plain, practical and eminently surgical manner, and no one can fail to receive some valuable information regarding the indications for uterine irrigation, and the method of performing it, which is of first importance. Another valuable paper is by Dr. J. F. W. Ross, entitled "How Should we Proceed when Abdominal Tumors are Complicated by Pregnancy." An admirable article on "Femoral and Ventral Hernia in Women," was contributed by Dr. Henry O. Marcy.

The transactions are printed in book form and upon excellent paper. The wood cuts are all good and well illustrate important features in many of the papers. Everyone interested in the progress of obstetrics and gynæcology should read these contributions.

TRANSACTIONS OF THE AMERICAN OTOLOGICAL SOCIETY. Published by the Society.

These transactions consist of the papers read at the Twenty-fourth Annual Meeting of the Society, which was held at the Arlington House, Washington, D. C., Sept. 22d, 1891, in connection with the Second Annual Congress of American Physicians and Surgeons.

While these transactions are chiefly of value to the aurist, still the general practitioner will find much useful matter in connection with his general practice. The volume contains, besides the proceedings, fourteen papers of excellent merit, embracing the latest knowledge concerning the science of otology. Some of the papers are exceedingly interesting, especially several dealing with the operative treatment of mastoid disease. The Society is to be congratulated on the good work it is doing.

CORRESPONDENCE.

BONE IN THE THROAT.

EDITOR OF THE MEDICAL AND SURGICAL REPORTER:

Seeing a report of cases of bones in the the throat in the REPORTER recently brings to my mind a case that came to me several years ago. A lady about fifty years of age was eating of baked chicken, and accidentally swallowed a bone, which lodged in the esophagus several inches below the pharynx. She immediately sent for a physician, who thought that in time it would work down; if not, it would require an operation. The patient became somewhat alarmed at her situation and sent for another physician, who likewise feared that an operation would have to be performed. He called me in consultation.

When I arrived, I found the patient eating Indian pudding and milk, some four hours after swallowing the bone, which she felt distinctly where it had first lodged. The family had devised this plan of swallowing something to take the bone down, but were taking only small quantities of milk and pudding, finely mashed, at a time. Liquids were also tried, but none of them were of any avail. I told her that the pudding and milk was the best plan they could have devised; but, instead of taking small quantities at a time,

she should take as large a spoonful of pudding as she could swallow without chewing it up, and that would distend the esophagus and take the bone along with it. I advised her to try it at once.

The attending physician then took me into an adjoining room to consult over the case. We were scarcely seated before her husband came into the room and stated that the bone had gone down. Only two mouthfuls were sufficient to dislodge the offending bone. JOHN M. CURRIER.
Newport, Vt., April 27, 1892.

LITERARY NOTES.

LITTLE THINGS.

It is curious to note that many things which have turned out most useful discoveries for man, having a great influence upon the lives and destinies of mankind, owe their beginnings to some slight accident.

It is said that the art of printing took its origin from some rude impressions taken (for the amusement of children) from letters carved on the bark of a beech-tree.

Gunpowder was discovered from the falling of a spark on some materials mixed in a mortar.

The stupendous results of the steam-engine may be traced to the boy who sat watching the steam which came from the nose of the tea-kettle.

Electricity was discovered by a person observing that a piece of rubbed glass attracted small bits of paper.

Pendulum clocks were invented after Galileo stood observing the lamp in a church swinging to and fro.

The telescope we owe to some children of a spectacle-maker placing two or more pairs of spectacles before each, other and looking through them at the distant sky. Their idea was followed up by older heads.

Sir Isaac Newton was sitting in his garden one day when he saw an apple fall from a tree. This common occurrence set him to thinking why things should fall down and not up, and this train of thought led him to the discovery of the law of gravitation.

Every one can now appreciate the importance of the slight matters spoken of, because the wonderful results are now before the world. But the beginnings of these things were treated with ridicule and scorn. No matter how unimportant a circumstance appears, it is quite possible that great results may come from it. In a small building which was once Peter the Great's workshop in Holland is the inscription: "Nothing is too little for the attention of a great man."—*Harper's Young People.*

BABYHOOD, the mother's nursery guide, continues in its May issue the medical articles on catarrhal affections and their complications in children, and the treatment of the headaches of childhood. A good deal of space is devoted to the question of "What We Would Do With Him," the case being that of a particularly wayward and unmanageable child, whom a number of mothers would treat each in her own way. Under "Nursery Problems," advice is given as to the suitable time for weaning, the disagreeing of milk, learning to sit upright, constipation, taking cold easily, club feet, suspicion of worms, etc. There are also articles on "Dressing the Baby After Six Months," "Occupations and Amusements," "Primary Musical Education," etc.

THE MEDICAL DEPARTMENT OF THE GERMAN ARMY.

IN accordance with the principle that the maintenance of the efficiency of the army is the prime condition of final success, and that the care for the troops is one of the most important duties of the commander and the administration, the greatest attention has been paid in the German army to sanitary matters. The system is divided into the medical *personnel* and the sanitary institutions. The former comprises all sanitary officers, including the apothecaries, who rank with administrative officials, the non-commissioned surgeons and apothecaries, the hospital stewards, the nurses, and, in war, the men carrying away the wounded. The sanitary institutions comprise, in peace, the garrison hospitals and regimental wards for sick soldiers; in war, the sanitary detachments, the field hospitals, the war *etappen* and reserve hospitals, and the sanitary trains upon the railroads.

The highest authority in peace is the Medical Department of the Prussian War Ministry; in war, the chief of the sanitary service, who is attached to the head-quarters

of the army. Under the direction of the Surgeon-General of the army, a surgeon-general supervises the sanitary service of each army corps. In Bavaria and Saxony a sanitary department or a sanitary director takes the place of the Surgeon-General. In each division the surgeon oldest in rank has general charge of the sanitary affairs, while the practical work devolves upon the staff and assistant surgeons attached to every body of troops, who are in turn assisted by non-commissioned surgeons. All surgeons have the rank of officers, and occupy positions of absolute equality with the latter.

It may be mentioned here as a matter of interest that the death rate of the German army in peace is smaller than that of any other standing army. The same applies to the number of sick and disabled persons.

In war every sick or wounded soldier, as well as any person charged with the care for the same, is protected by the stipulations of the Geneva Convention. All those connected with the sanitary service carry, therefore, the well-known badge, the red cross on white ground, which is also painted on every wagon belonging to the service, while a flag showing the same emblem floats over every hospital. Red flags, or red lanterns during the night, make known at large distances the places where the wounded are collected and where the field hospitals are established.

Every soldier carries a small package of bandages, and around his neck a badge with his name, for purposes of identification. Every hospital steward carries a satchel with bandages and a bottle with restoratives, every surgeon a case of instruments. Every battalion of infantry or regiment of cavalry is followed by a medicine-wagon, filled with medicine and bandages, stretchers, and everything else necessary for the care of the wounded or sick soldiers during march or battle.

The voluntary medical service has become a valuable adjunct to the military sanitary service since it has been regulated by proper rules. It is under the direction of a commissioner appointed by the Emperor, and many excellent young men entered its ranks during the late war who were incapacitated from some cause for other service. Many eminent physicians devoted themselves likewise to care for the sufferers by accepting positions as consulting surgeons-general.—From "The German Army of To-Day," by Lieutenant-Colonel Exner, in *Harper's Magazine* for May.

PERISCOPE.

THERAPEUTICS.

ICHTHYOL.

Among cutaneous diseases, Dr. Charles (*The Lancet*, Sept., '91) found ichthyol, in an ointment of two to ten per cent., especially valuable in burns of the first and second degrees and in scalds. Externally and internally, it was very efficacious in erythemata of unspecified nature. Several rapid cures of chillblains were obtained by washing with hot water and ichthyol soap, and subsequent application of ichthyol and turpentine, equal parts; of ichthyol and glycerine, equal parts; or of ichthyol, three parts, glycerin, water and dextrin, all ten parts. In intertrigo it was also useful, as well as in zoster and in eczema, in acne and acne rosacea, in sycosis and in psoriasis. He also found the ichthyol treatment very efficacious in boils, carbuncles and erysipelas.

MEDICATED SOAPS.

A. Santi, of Bern (*Correspondenzbl. für Schweizer Aerzte*, No. 13, xxi. Jahrg. 1891), speaks in praise of medicated soaps, which, within the last few years, since they have been manufactured (especially abroad) to suit the requirements of the physician, have come into good repute. Soaps easily penetrate the epidermis: hence drugs are more active in this form than in ointments. The method is cleanly, cheap, and more agreeable to the patient than that of ointments. The soaps manufactured according to the formula of Unna are first considered. The soap-mass, in the first place, reacts absolutely neutral, and is composed of the best beef tallow and freshly prepared soda and potash lye, two or three (in summer) parts soda to one of potash, which latter acts more effectively than soda on the horny layer of the epidermis. To obviate the drying effect of even neutral soap on the skin, the soaps are all superfatted with about four per cent. free fat, for which purpose olive oil is used. The following soaps in cake form

are mentioned. They contain marble, ichthyol, salicylic acid, zinc oxide and salicylic acid, tannin, tannate of soda, oxide of zinc and tannate of soda, zinc tannate, rhubarb, tar, sulphur, tar-sulphur, camphor, camphor-sulphur, iodide of potassium, soda and naphthol-sulphur.

A superfatted potash soft soap has also been made by Unna and Micek.

THE TREATMENT OF ACUTE MUSCULAR TORTICOLLIS.

This disease has been recognized for many years, but has not received very extensive notice at the hands of systematic writers upon the diseases of children. Acute torticollis generally appears suddenly, perhaps after rapid motion of the affected parts, or it may appear spontaneously. The pain may be intense, even after the slightest exertion, and this is the most prominent symptom. It is located in the cervical region, but may include the entire area of the trapezius muscles. With the pain there is also muscular contraction causing more or less distortion of the head and neck. The top of the trapezius muscle is the initial location of the contraction in the majority of cases. In the spasmodic form of the disease there is clonic contraction of the muscles. In addition to the symptoms mentioned, there may be malaise, loss of appetite, slight fever, and insomnia. The contracture diminishes after a few days, the pain becomes less severe, and the head resumes its normal position. The disease is especially common in childhood and adolescence, it is rare in adults and old age. It is more common in boys than in girls. It is related to rheumatism, and is sometimes called *torticollis a frigore*. Syphilis associated with rheumatism is also an occasional cause. Cervical arthritis may result in an osseus torticollis which sometimes resembles acute muscular torticollis. Rheumatic or scarlatinal arthritis may also simulate it. Acute muscular torticollis may also resemble lumbago, the latter being sometimes exclusively of a muscular character and the cause of rheumatism, or muscular rupture. With reference to contractures, two varieties of torticollis may be mentioned: (1) that form which is caused by muscular effort, true traumatic torticollis, in which the contracture is caused by the slight twisting of the cervical articulations, perhaps by the rupture of muscular fibres. (2) the spontaneous form which results from mild arthritis in the cervical region, or from idiopathic muscular rheumatism involving the muscles of the neck. The acute form of torticollis resembles the chronic one, but in the former the symptoms improve and disappear, in the latter they persist and become aggravated. The acute form is usually recovered from, even though it may be untreated, but it may pass into the chronic form if neglected. Rest, warm applications, and anodynes subcutaneously will relieve the pain in most cases, but an exclusively medical treatment is not very efficacious nor practical. Other useful means of treatment are massage, suspension in Sayre's extension apparatus, and electricity.—Chocas, *Rev. Mens. Mal. Enf.* Oct. 1891.

BENZINE IN TRICHINOSIS.

In a case where a large number of persons had partaken of pork which was discovered a few hours later to have been plentifully supplied with this detested infection, a physician administered 40 minims of benzine in capsules and followed it by a cathartic. Not one of those thus treated was afterward known to have suffered from trichinosis.

THE TREATMENT OF IMPOTENCE IN MEN.

Dr. Victor V. Gyurkovecky, in the *Wiener medicinische Presse*, 1891, presents two papers (No. 46, S. 1738; No. 47, S. 1780). He reports complete cure by suspension in Sayre's apparatus in three cases of sexual neurasthenia. In cases where this condition is the result of gonorrhœa, he anoints his catheter or endoscope with balsam of copaiba to get its effect upon the mucous membranes, makes a thorough examination and cures the local condition. He has treated with benefit one case, and to no effect one case of masturbation (a most frequent cause of impotence), by hypnotic suggestion. In sexual neurasthenia he has treated two cases by hypnotic suggestion, one to a cure and the other with benefit, although he is yet under treatment. From these cases he concludes that hypnotic suggestion is a powerful remedy for masturbation, pathological pollutions, and the various forms of impotence.

THE TREATMENT OF CYSTITIS WITH MERCURIC CHLORIDE.

Guyon (*Annal. des Mal. Génito-urinaires*, xi.) recommends mercuric chloride in the treatment of cystitis. The results are especially good if the cystitis be tuberculous. Irrigation or instillation may be employed. The mercurial solution may vary from 1:5000 to 1:1000. At first, from twenty to thirty drops are instilled, by means of a syringe, into the prostatic urethra, the quantity being gradually increased to a dram. The bladder must be evacuated after each instillation. In gonorrhœal cystitis, good results were obtained from instillations of silver nitrate, 1 or 5: 100.—*Münchener med. Wochenschr.*, 1892, No. 5, p. 81.

TREATMENT OF GRIP.

Dr. Roland G. Curtin, in the *Therapeutic Gazette*, writes: For the first time since 1889, a recurrence to old therapeutic measures has been of service. The fever mixtures of antiquity seem at least to allay fever, induce quiet and sleep, produce perspiration, and hasten recovery. The standard saline and other fever mixtures seemed to be again efficacious.

For the initial symptoms, salicin still seems to be the best and safest remedy, both as a tonic and an antipyretic, in doses of from 10 to 30 grains. Each dose will often be followed by marked relief, and the occurrence of perspiration, with a fall in temperature. No remedy seems to show the same direct results, unless it be antipyrin or phenacetin, which are decidedly more unsafe, though not so unsafe as in the preceding years, since the tendency to dangerous heart failure seems now much more rare. Salicin may be combined with small doses of phenacetin, antipyrin or sodium salicylate.

The formula most agreeable is,—

℞ Salicin, ʒiii;
Sodii salicyl., ʒss; vel Phenacetin, gr. xvi;
Syrup. acaciæ, fʒvii;
Aquæ, fʒix;
Olei gaultheriæ, gtt. xv.
Sig.—Teaspoonful every hour or two. M.

For the delirium and insomnia, sulphonal is the best and most efficacious soporific.

Ammonium iodide, in 2-grain doses every hour, until iodism is produced, hastens recovery in the later stages of pulmonary catarrh and asthma.

Ammonium chloride has proved more useful this year than heretofore.

Nausea is best controlled by cocaine, in doses of $\frac{1}{12}$ grain every two hours in solution. In severe cases feeding by the stomach must be withdrawn and rectal feeding employed, champagne and plain soda-water from the siphon being given to quiet the stomach and allay thirst.

Catarrhal jaundice has been frequently observed, generally in children, and treated by small doses of calomel and sodium phosphate, with speedy recovery.

In any case with *bilious* vomiting, 2 grains of bicarbonate of sodium and $\frac{1}{8}$ grain of calomel may be employed until some action of the bowels has been produced.

A SPECIFIC FOR TETANUS DISCOVERED.

Dr. R. Schwartz, of Padua, announces the successful treatment of tetanus by means of injections of the tetanus antitoxin of Tizzoni and Caltani. These experimenters succeeded in producing immunity against tetanus even in animals susceptible in a high degree, and have shown that the blood-serum exerts an antitoxic action, and is capable of producing immunity against and cure of the disease. They succeeded in obtaining this tetanus antitoxin in a solid state by the addition of alcohol to the serum, and by drying the precipitate *in vacuo*. As the disease in man is of a longer duration and less certainly fatal than in many animals, there seemed to be good reason to hope that the tetanus antitoxin might be of great value. Gagliardi, of Molinella, treated a severe case by hypodermic injection of one gramme. All symptoms of tetanus disappeared and complete recovery ensued. Schwartz relates at length the case of a peasant boy, aged fifteen, treated by him.

ANTIPYRIN IN HEPATIC COLIC.

Dr. Kraus (*La Semaine médicale*, No. 61, 1891) recommends antipyrine in hepatic colic. Given in the beginning, it calms the pain, and even may abort the attack; if administered later, it exerts an injurious influence, and may aggravate the patient's condition. Here morphine replaces it, and, when an attack has lasted two or three hours, an injection of morphine, instead, should be immediately given.

EARACHE.

Take five parts of camporated chloral, thirty parts of glycerine, and ten parts of oil of sweet almonds. A piece of cotton is saturated and introduced well into the ear, and it is also rubbed behind the ear. The pain is relieved as if by magic, and if there is inflammation it often subsides quickly. —*Medical Brief.*

ACUTE IODISM AND ITS DANGERS IN SYPHILIS.

E. Finger discusses this subject in *Gazette Lekarska* (No. 24, 1891). The headache may reach an alarming intensity, symptoms of cerebral compression, vomiting, vertigo, delirium, staggering gait, somnolence and coma may supervene. One case showed alarming depression of the heart's action. Neuralgias of the cerebral nerves often occur. These symptoms are probably due to an increased cerebral circulation in vessels which have undergone specific alterations. Consequently caution is necessary in the administration of iodides in patients showing cerebral symptoms. The best method of obviating unpleasant effects is to give the iodide in milk; Belladonna may be added, as well as potassium bromide.

BROMAMIDE, A NEW ANTIPYRETIC AND ANTINEURALGIC REMEDY.

Dr. Augustus Caillé, writes in the *N. Y. Medical Journal:* This drug is described by its discoverers, Messrs. F. H. Fischedick and Charles E. Koechling, of New York city, as a new bromine compound of the anilide group containing seventy-five per cent. of bromine ($C_6H_2Br_3NH.HBr$).

It is in the form of colorless, needle-shaped crystals nearly odorless and tasteless, insoluble in hot or cold water, slightly soluble in cold alcohol, and soluble in sixteen parts of boiling alcohol. Chloroform, ether, and the fixed oils dissolve it, but it is insoluble in benzine. Its action toward litmus paper is neutral. It is a very stable compound, not being affected by any of the ordinary reagents. It melts at 243° F., and volatilizes at 310° F. Without change, subliming in beautiful feathery crystals.

Bromamide was first given to dogs and rabbits, in doses of 2 grammes (30 grains), without noticeable deleterious influence and without affecting the composition of the blood in these animals. The administration of from 0.6 to 1 gramme (10 to 15 grains) to healthy adults was followed by a slowing of the pulse *without sweating.* The administration of 0.06 to 0.2 gramme (1 to 3 grains) to children from one to three years of age was accomplished without untoward symptoms.

The experiments as to the therapeutic properties of bromamide were carried on at the German Hospital from June 1 to November 1, 1891, and suffered embarrassing interruption in the beginning of the experimental term, in consequence of the resignation of the entire house staff. Bromamide was administered in the following class of cases: Typhoid fever, acute articular rheumatism, chronic rheumatic arthritis, chronic nephritis, acute fibrinous pneumonia, rheumatic fever with acute endocarditis, general and localized dropsy due to hepatic, renal, or cardiac disease, and diverse forms of neuralgia; and special attention was given to a possible antipyretic, diuretic, diaphoretic, antineuralgic, and sedative action of the drug.

Bromamide was administered symptomatically in a number of cases of neuralgia from various causes.

1. Compression myelitis, with intercostal neuralgia. No beneficial effect from 10 to 20 grains of bromamide.

2. Premenstrual headache, 15 grains of bromamide; marked relief in two hours.

3. Reflex hemicrania from carious tooth; 15 grains of bromamide; relief in three hours.

It will be seen from a perusal of the foregoing that the trials thus far made are encouraging, and may warrant further experiments, especially in other forms of disease.

Bromamide has the power of reducing the temperature in most cases of febrile disease from 1° to 2.5° F., without the excessive sweating as produced by other antipyretic drugs. It has, according to the above-recorded experiments, no pronounced diuretic action, and it is, so far as could be ascertained, free from unpleasant symptoms as regards the digestive tract. The lancinating abdominal pains noticed in several of the severe forms of disease can not fairly be attributed to the use of

bromamide, because such phenomena were never observed when the drug was administered to healthy subjects.

Bromamide can safely be given in 10-to 15-grain doses several times a day, as an antipyretic and anti-neuralgic to adults, and in doses of from 1 to 5 grains to children. It may be given in capsule, in water, or dry upon the tongue, or suspended in a fluid.

In conclusion, I take pleasure in expressing my indebtedness to Dr. Kurth, Dr. Inglis, and Dr. Moscovich, of the house staff, for valuable assistance in securing these notes.

MEDICINE.

A NEW METHOD OF MEASURING THE CAPACITY OF THE STOMACH.

At the recent Italian Medical Congress, Forlanini (*Rif. Med.*, October 24, 1891) proposed a new method of ascertaining the presence of dilatation of the stomach. He passes an œsophageal sound into the stomach, and by its means distends the organ with air, in no case using a pressure of more than seven or eight centimeters of water; the air is then withdrawn by means of an aspirator and its volume ascertained. By always using the same amount of pressure when injecting, the effects of any treatment on dilatation of the stomach can be readily ascertained.—*Brit. Med Jour.*

THE ANTISEPTIC FUNCTIONS OF THE LIVER.

Dujardin-Beaumetz (*Gazette Hebdomadaire de Medicine et de Chirurgie*, Aug. 15, 1891), writing concerning the antiseptic functions of the liver, says that while, at the present day, it is proved beyond doubt that the liver possesses antiseptic powers, there are no signs which show definitely when this function is being properly fulfilled. The problem has been approached in various ways. Hayem and Tissier claim that the presence of urobilin in the urine is a sign of a morbid condition of the hepatic cells. The presence of urobilin is easily detected by the spectroscope. It is certain that its presence indicates some derangement of the liver-cells, but such derangement often exists without any urobilin in the urine. Roger claimed that a correlation exists between the glycogenic and antiseptic functions of the liver, and it is only necessary to determine the condition of the former to judge of the latter. But this is not to be relied on. A third method of determining the condition of the antiseptic function of the liver is by determining the toxicity of the urine. But this is not reliable, as jaundice is frequently present, and bile is much more toxic than the urine. To maintain the integrity of the antiseptic function, we must attempt to increase the glycogenic power and to shut off the supply of poison. The first object is attained by a nourishing diet and by keeping down the temperature; the second by intestinal antisepsis, favoring elimination and diminishing cellular activity.

The best antiseptics are salol and bismuth salicylate. Purgatives are of use only when there is constipation. Favor diuresis by copious draughts and by mild alkalines, and keep the skin active by baths and friction. Forbid meat and hard work, either bodily or mental.—*Univ. Med. Mag.*

PATHOLOGY OF THE NERVE PLEXUSES OF THE INTESTINES.

Bouome (*Archivio delle Scienze Mediche*) after an extended series of researches, comes to the following conclusions:

1. Extirpation of the cœliac ganglion, with partial destruction of the solar plexus, produces constantly in rabbits atrophy of intra-intestinal nervous plexus, accompanied with profound atrophy of the liver and spleen and general marasmus.

2. Atrophy of the intestinal plexus and general marasmus are more pronounced when there develop neuromata and fibroneuromata after the extirpation of the cœliac plexus.

3. There exists no relation between the nutritive activity of the intestinal plexuses and the muscular tone of the intestines.

4. Obstructing the circulation in the intestines produces throughout the entire length of the intestine where such obstruction exists, a true necrobiosis of the plexuses of Meissner and Auerbach.

5. In cases of a chronic saturnism, the author observed complete degeneration of the plexuses of the intestine, accompanied with an advanced sclerosis of the semilunar ganglion and of the entire solar plexus.

6. In individuals with chronic catarrh of the intestines, the author observed simple and pigmented atrophy of the plexuses of Meissner and Auerbach.

DIAGNOSIS OF LESIONS OF THE OPTIC LOBES.

Eisenlohr reports the case of a young man, twenty-eight years of age, who was struck in the head with a bullet from a revolver, the ball being found in the tubercula quadrigemina at the necropsy, who developed the following symptoms:

1. Tremor of the left arm, with unequal pupils, following secondary irritation of the pyramidal tract.

2. Associated paralysis of the eye-muscles, with diminution of the acuteness of vision, this latter symptom being due to a lesion of the optic lobes, the ophthalmoplegia depending upon a concomitant lesion of the nucleus of the occulo-motorius.

3. Polyuria without glycosuria, cerebellar ataxy, and finally symptoms of cerebral compression. The writer emphasizes the existence of visual and pupillary disturbances in lesions of the optic lobes.—*Rivista clinica e Terapeutica, 15, 1891.*

RECURRING OCULAR PARALYSIS.

In the *Riforma Med.* quoted in a recent *Centralbl für Klin. Med.*, Massalongo directs attention to the condition of so-called ophthalmoplegic migraine. This was at first regarded as a periodic or recurring weakness of the third nerve, depending upon an affection of the nuclei until Charcot first gave it the name which we have used above. The author found at a necropsy on a patient suffering in this way that the symptoms depended on an inflammatory process or a new growth in the pia at the base of the brain, which affected the nerves which were pressed upon, and so increased the vaso-motor effects to which the varying conditions by exposure to cold, excitement, depression, menstruation, or dyspepsia gave rise. Such an explanation of the phenomena in one case suggests the possible presence of a demonstrable lesion in others to account for symptoms which, although associated with headache, have probably no necessary connection with migraine.

SURGERY.

THE TREATMENT OF REDUCIBLE HERNIÆ BY THE INJECTION OF ALCOHOL.

Edward Steffen of Zurich, during the past three years, has treated 326 cases of reducible herniæ by Schwalbe's method, and has published the results in the *Correspondenzblatt für Schweizer Aerzte.* In most instances the patients were able to continue their work during treatment. After the injection the puncture was cleaned and covered with mercurial collodion. Notwithstanding, in a few cases, sloughing took place; but this acted rather beneficially than otherwise. The number of injections in a single case varied 6 to 168, the latter extending over a period of two years and a half. A medium-sized rupture in an adult required from 80 to 100 grammes of alcohol. The author used alcohol 70 per cent. in doses of one to four grammes, substituting in exceptional cases extract of oak bark. Latterly he found the addition of phosphoric acid, in the proportion of 1 to 200, advantageous. In thirteen cases the result of the treatment is not known, in twenty-nine a cure was not possible from various causes, such as obesity or size of the rupture; of the remainder, 245 cases are reported cured and 19 improved. The longest time taken to effect a cure was four years, the shortest one year. Of 257 inguinal herniæ, 216 cases were cured and 16 improved, with 23 relapses. Of 13 femoral herniæ, 9 were cured and 2 improved, with one relapse. Of 19 umbilical herniæ, 17 were cured, with no relapse. Of 4 herniæ in the linea alba, 3 were cured, the other improved. It appears that the more recent the herniæ and the younger the patient the more favorable the prognosis, and the ambulant treatment, with intervals of three to seven days between the injections, gave better and more lasting results than the treatment in bed with daily injections.—*Lancet.*

INDICATIONS FOR COLOTOMY.

Dr. Kelsey, (*Therap. Gazette*, Jan. 1892) gives the following indications for the performance of colotomy:

1. In all cases of cancer which cannot be completely extirpated, where the disease is liable to produce any degree of ob-

struction, or is broken down and discharging into the rectum. It is possible to have cancer near the rectum which will cause no symptoms referable to the rectum, and hence furnish no indications for operation.

2. In all cases of incurable non-malignant ulceration where the disease is too extensive to admit of complete resection of the ulcer.

3. In all cases of threatened obstruction where the obstruction cannot be permanently overcome by attacking it directly; for example, the obstruction due to old pelvic cellulitis in women.

4. In all cases of recto-vesical fistula.

5. In cases of congenitial malformation where the rectal *cul-de-sac* cannot be dissected out and brought down to the surface.

THE VARIOUS SURGICAL PROCEDURES DEVISED FOR THE RELIEF OR CURE OF TRIGEMINAL NEURALGIA (TIC DOULOUREUX).

Victor Horsley says neuralgia is a term of somewhat vague import, merely implying the existence of pain as a result of some morbid condition of the nerves. The nerve affected in this case is the fifth, or trigeminal. Pain may be situated in any part of its region of distribution, and may depend upon an affection of any branch of one of its three main divisions; pain is peculiar in several respects. It is intense and paroxysmal with frequent intervals of freedom which may extend over days or hours, or may be limited to only a few seconds. It is often confined to a particular branch of one of the divisions, and may extend to all three divisions of the nerve. The tender spots, or foci, were first pointed out by Valleix and are as follows: The supraorbital notch, the junction of the nasal bone and cartilage where the nasal nerve emerges, and the inner angle of the orbit where the trochlear branch becomes superficial. Other points, which are less frequently the seats of pain, are the upper eyelid and the eyeball itself. In the second division the most common foci are the infraorbital foramen and the malar foramen in the malar bone. In the third division the inferior dental nerve and the lingual are the most common seats of severe pain, sometimes experienced in the auriculotemporal region just in front of the ear, and rarely in the lower lip. The author recommends the treatment by drugs being thoroughly tried. Probably the best results are got from quinine, especially in combination with arsenic, and from gelsemium; antipyrin is also useful in some of the slighter cases. Opium can only be regarded as a palliative. Chloride of ammonium is sometimes efficacious, and aconitin is recommended by Dr. Seguin. Counter-irritation in the form of blisters over the point of emergence of the nerve, or along its course, are also useful, and not infrequently give great relief. Chloride of methyl may be mentioned, but its efficacy, he thinks, in this condition would be slight. Galvanism is good in some cases. The operative procedures are of four different kinds, namely, nerve-stretching, nerve-division, or neurotomy, the excision of part of the nerve, or neurectomy, and nerve-avulsion. Another way in which a part of the nerve is occasionally destroyed, is by thrusting into the foramen of exit a red-hot wire, but there is reason to suppose that it will never come into general use. He proceeds to consider in detail the different branches of the fifth nerve; to describe the operations themselves, and the various modifications which they have from time to time undergone, and the results which may be hoped for from them. —*British Med. Jour.*, Nov. 28, 1891.

OBSTETRICS.

INTRA-UTERINE TRANSMISSION TO THE FŒTUS OF PATHOGENIC BACTERIA.

Lubarsch's (*Rev. Mens. des Mal. de l'Enf.*, September, 1891) investigations were made upon rabbits, guinea pigs, and rats, thirty-nine in all, with 106 fœtuses. Sub-cutaneous, intra-venous, and intra-peritoneal methods of inoculation were practiced with cultures of anthrax, the pneumo-coccus of Fränkel, and the *bacillus enteritis* of Gärtner. The following results were observed: Of seven rabbits, which were allowed to die from anthrax, transmission to the fœtus was observed in two cases by means of the microscope and cultures, in one case by means of the microscope alone, and in one case by cultures alone. Of twenty-one guinea pigs, positive results were demonstrated in six cases with

the microscope and cultures, in two by cultures alone, and in two by the microscope alone.

Of three rabbits, which were inoculated with the pneumo-coccus, positive results were determined in two with the microscope and cultures. One guinea pig was inoculated with the *bacillus enteritis*, the result being negative. How can we explain the inconsistent transmission of the micro-organism to the fœtus?

The author does not concede that pathological modifications of the placenta, from hæmorrhage, etc., play the preponderating rôle, which has been attributed to them by Wolff, Malvoz, Virchow and Birco-Hirschfield.

He believes, rather, as the result of his experiments, that the bacilli can traverse intact epithelium, and that this does occur in the transmission of the bacilli to the fœtus. If this transmission does not occur very frequently, it is due to the fact that the micro-organisms, and especially the bacteria of anthrax vegetate for only a very short time in the placenta, and that proliferation in the animal organism varies with the species, and is often very limited.

PARTIAL STARVATION OF THE FŒTUS IN CASES OF CONTRACTED PELVIS.

In discussing premature labor (*Amer. Jour. Obstr.*, March. 1892), Dr. Bettman says: This paper would not be complete without reference to an entirely new solution to the question of moderately contracted pelvis proposed by L. Prochownick, of Hamburg, in August, 1889. Prochownick tried the novel experiment of stunting the growth of the fœtus in utero by starving the mother, or, rather, by placing the mother on the ordinary diet for diabetics. His first patient had been delivered of four children; two prematurely, one by version, one by perforation; and all the infants had perished. Toward the close of the fifth pregnancy the patient was placed on the strict diet, and was delivered at term of a healthy infant weighing five pounds, three ounces, with adipose layer practically wanting, and with very movable skull bones. The infant developed rapidly and normally. Encouraged by his success, he repeated the experiment in two similar cases, and both the infants were born thin, had movable skull bones, and thrived perfectly. Thus three mothers who had born eight dead children were enabled by these means to rear living offspring. Prochownickh as found imitators, and in March, 1890, A. v. Brehm reported a fourth successful case in the St. Petersburg *Medicinische Wochenschrift.*

The departure of Prochownick is so novel, is based on such rational physiology and has been so signally successful that it merits not only the general attention of the obstetric world, but also general imitation in appropriate cases.

GYNECOLOGY.

CONGLUTINATIO LABIORUM.

Sanger (*Centralbl. f. Gynäk.*, in December 12th, 1891) read, before a recent meeting of the Leipzig Obstetrical Society, a paper on two distinct forms of adherent labia. The first variety was seen in a robust little girl, aged 3. The external labia were normal, the nymphæ seemed completely hidden. A thin membrane of the mucous type united the labia majora, looking at first sight like a hymen. It could be pushed downwards by the finger introduced into the rectum. It reached forwards to the clitoris, close behind which organ and a little to the left of the middle line lay a very minute orifice in the abnormal membrane, through which the urine could pass in a full stream. On passing a probe into this orifice and backwards, it could be plainly felt through the membrane, and on gentle pressure the membrane was torn through, with but slight hæmorrhage. The normal vestibule then came into view. The membrane proved to be simply the labia minora united together. The case was an example of Bókai's "epithelial union" of the labia, of which that observer described thirty-nine cases. It was clear that minute vessels ran in the uniting tissue. The second case was in a woman, aged 21, who consulted Sänger concerning an impediment to connection and irregular painful menstruation, with free show. The vestibule easily allowed the passage of the finger, but the introitus was reduced to a slit three-fifths of an inch long, immediately in front of the perineum. From this slit forwards to the mons veneris extended a broad and very conspicuous membrane, which stretched across between the labia majora, which it completely cov-

ered as far as the hair on each side. This membrane was over 2 inches long and over 1 inch broad. It was pigmented so as to appear of a brownish tint, and bore scanty hair. There was a little depression on its surface close to the mons. This membrane was marked with a kind of median raphé, paler than the general surface, and a number of thin streaks converged from without and before backwards till they joined the raphé. The finger could be passed under the membrane, which consisted of the labia majora fused together. The patient was narcotised, and a grooved director passed under the membrane, which was then cut through with scissors. There then appeared a longitudinal wound in each greater labium. Each wound was closed by an interrupted silk suture. The labia minora were ill-developed, the clitoris and its prepuce elongated and curiously flattened. The patient also had endometritis and congenital ectropion of the cervix, which was treated by scraping and the thermo-cautery. This patient, as her mother remembered, had been subject when a year old to a free yellow discharge, with great external soreness. It was treated by ablution and the application of potato meal; gradually a skin seemed to grow across the parts and the discharge ceased. The discharge was probably a vulvo-vaginitis, and may explain the true nature of many cases of so-called "congenital" conglutinatio labiorum.—*Brit. Med. Jour.*

GLASS PESSARY WORN TWENTY-FIVE YEARS.

R. A. Murray (*N. Y. Journ. of Gynæc. and Obst.*, January, 1892) recently exhibited before the New York Academy of Medicine a glass ball, hollow within, which a woman, aged 78, had carried in her vagina for about twenty-five years. He had considerable difficulty in removing it.

PEDIATRICS.

STROPHULUS INFANTUM.

Gebert (*Archiv für Kinderheilkunde*, 1891, Bd. xiii., Heft 3), with this title considers urticaria papulosa, or the lichen urticatus of older authors, and is of the opinion that hot baths, frequently repeated, act in producing the eruption. As the patients are often anæmic, iron is found useful, and for the itching small doses of antipyrine at night. The body should be sponged with dilute and cold vinegar at bedtime.

ANTIPYRINE IN CHOREA.

In a paper recently read before the Societé Médicale des Hôpitaux de Paris (*Bull. et Mem.*, Dec. 25, 1890,) Dr. Charles Legroux states the results of the treatment of chorea by antipyrine in sixty cases observed throughout their course. He found that antipyrine had a beneficial effect in two-thirds of the cases, rapidly diminishing the intensity of the disease and shortening its duration; recurrence, however, took place in three-fifths of the cases. In the cases in which the drug failed this was found to be due in some instances to intolerance (vomiting, diarrhœa, etc.,) or to cutaneous eruptions; in a few cases the drug seemed to have no effect on the disease. He found it necessary to give large doses and to reach the maximum dose in a short time. Between the ages of six and fifteen doses as high as three to six grammes (about ℥ iss to ℥ iij) a day were well tolerated for several weeks. Serious symptoms of poisoning were never observed, and in some cases in which an eruption or vomiting was at first noticed, when the use of the drug was resumed after a short interval, these symptoms did not recur. None of the cases treated had any rheumatic symptoms, but none were of a serious character.—*Medical Annals.*

INTUBATION AND TRACHEOTOMY.

In a report of these operations done at the Boston City Hospital, Drs. Prescott and Goldthwaite (*Boston Medical and Surgical Journal*, No. 27, 1891) drew the following conclusions: Three hundred and ninety-two cases of intubation, and 139 cases of tracheotomy have been reported, with a mortality-rate of 79.59 per cent. in the former, and 88.5 per cent. in the latter; 2,815 cases of intubation, and 24,941 cases of tracheotomy have been collected and analyzed, showing comparatively no difference in the mortality-rate of the two operations. The results depend more upon the nature of the epidemic than upon the operation. With intubation the results depend more upon the skill and experience of the operator than with tracheotomy.

Thirty-seven cases were seen at least a year and a half after recovery from intubation, with perfect voice, and with nothing that would indicate any ulceration from pressure of the tube.

THE TREATMENT OF DIPHTHERIA.

To what extent principles of treatment of cases of infective disease may be modified by the acquisition of true knowledge concerning the true nature of such affections is well shown in a paper read recently before the Clinical Society of Paris by M. Barbier, in which he dealt with the subject of diphtheria (*La France Médicale*, Jan. 1, 1892). He pointed out that the researches of Klebs, Loeffler, Roux and Yersin, and others have now conclusively established that the pathogenic agent is a bacillus which is only to be found in the false membranes, and does not penetrate either the blood or tissues. That discovery decides the much disputed question of the "local" or "general" nature of the malady. The "false membrane *is* the disease," and the primary object of all medication must be to detach and remove it wherever it is accessible; for one removes thereby not only the morbific agent, but the toxalbumens which the microbe elaborates, and which are the source of the symptoms. But experiment also teaches that the bacillus does not develop on healthy or non-excoriated mucous membrane, and it is therefore of chief importance that the false membrane should not be detached violently, but gently and slowly. Cotton wool held in forceps gently, and with frequent, patient repetition brushed over the false membrane, will gradually detach it; but care must be taken not to touch any other part. This is the first step. The next is to apply to the affected area such an antiseptic solution as has been proved by experiment to destroy the bacillus. Under M. Grancher, M. Barbier had largely studied this subject experimentally, and found carbolic acid to be the best parasiticide for this purpose; and he now recommends the application of a mixture of sulphovicinic acid (100) and carbolic acid (20) as more efficacious than carbolic acid and glycerine or olive oil, as hitherto adopted. This "*phenol sulphovicine*" causes a transitory sensation of heat and burning, but its taste is not very pronounced, and, he says, children tolerate it well. Moreover, although frequently applied—every hour by day, every two hours by night—M. Barbier has never seen any sign of carbolic poisoning. Before applying it each time there should be practised free irrigation of the naso-pharynx, which aids in detaching more membrane, the warm water being rendered antiseptic by the addition of a small quantity of an alcoholic solution of salol (1 in 40). He claims for this procedure, vigorously carried out, a marked amelioration in the more serious signs of infection—the redness of the throat, glandular swelling, constitutional symptoms and albuminuria. Similar principles he applies to the after-treatment of tracheotomy in laryngeal diphtheria; and he advises the prescription of calomel and naphthol to promote intestinal antisepsis, rendered necessary by the swallowing of portions of membrane detached from the fauces. Then general tonic treatment, with plenty of fresh air and sunlight and avoidance of close rooms and steam. He gives no statistics, but he claims to have seen many good results from adhering thus rigidly to the teachings of the laboratory; and certainly there is no greater field for the study of diphtheria than the Paris Hôpital des Enfants Malades, where M. Barbier's observations have been made.—*Lancet.*

HYGIENE.

THE DIGESTIBILITY OF CHEESE.

It is the general opinion of the laity that the eating of cheese after taking food is an assistance to digestion. This view seems not to be in accord with the result of experiments made by von Klenze, as recorded in the *Allgemeine medicinische Central-Zeitung*, Number XVIII, 1891. He made very thorough tests of the various forms of cheese found in the dietary lists. For the experiments he used an artificial digestive fluid, to which were added fifty cubic centimeters of fresh gastric juice and three cubic centimeters of hydrochloric acid. Into this he placed a gramme of the cheese to be examined. Eighteen varieties were tested, and the following deductions made: Chester and Roquefort cheese took four hours to digest: genuine Emmenthaler, Gorgonzoler and Neufchatel, eight hours; Romadour, nine

hours; and Kottenberger, Brie, Swiss, and the remaining varieties, ten hours. Considering that in a healthy stomach digestion after an ordinary meal is completed in from four to five hours, it would seem from von Klenze's studies, that Chester and Roquefort cheese were the only kinds that were likely to be digested within this length of time, and that the other varieties, some of which are largely in use, not only did not assist digestion, but actually retarded it.—*New York Medical Journal.*

TO PREVENT THE SPREAD OF ENTOZOA.

Dr. Prospero Sonsino advocates the following sanitary measures to prevent the dissemination of entozoa among human beings:

1. If possible the sewers should empty their contents into the sea, but never into a stream. The adoption of a system of irrigation is advisable, if the above is not practicable, provided that the irrigated soil is planted only with such vegetables as are eaten in a cooked state, or better still, with plants which are not edible.

2. If the above-mentioned measures cannot be employed, and the destruction or disinfection of fæcal matter cannot be carried out in general, these precautions should at least be adopted in asylums, schools, and hospitals—the excreta being disinfected by heat, sulphuric acid (10 per cent.) or large quantities of lime.

3. Persons engaged in certain kinds of work—such as in mines, tunneling, rice plantations, etc., should be compelled to defecate at places where the fæcal matter can be disinfected. The fæces of new comers should be microscopically examined for entozoa before they are allowed access to the works, and it would be well to examine them periodically, so as to remove the infected persons at an early period.

4. Veterinary inspection of slaughter houses should be made daily, and all organs and parts of slaughtered animals which are found to contain entozoa.

5. The admission of persons infected with entozoa into hospitals should be made easier than it is now.

6. The pens in which hogs are kept should be inspected.

7. Dogs should be kept away from slaughter houses.—*Centralb, f. d. Medicin. Wissensch.*, No. 2, 1891.

FETID FEET.

The cause of this unpleasant ailment is to be found in the unnatural custom of wearing shoes. Nature contemplated a shoeless animal when she made man, and she so arranged the epithelium on the soles of his feet as to provide for a reproduction of the layers worn off in walking. So well suited to man's necessities was this arrangement, that Parkes, after discussing the merits of various foot-gear, concludes that the best shoe for soldiers is no shoe at all. But man had to improve on nature, and the way he has done it is by encasing the foot in an impermeable casing of tanned leather. This prevents the removal of the epithelium from the sole, and also prevents the escape of perspiration, which, keeping the dead epithelium moist, infallibly renders it odorous.

The reason why washing does not relieve this is, that soap and water alone are insufficient to remove the epithelium. No amount of rubbing will do this, and it is doubtful if anything short of a vigorously wielded scrubbing-brush will do so. But the Greeks had something better even than this. Some of our readers will remember the description given by Xenophon of the games instituted by Cyrus, before his march to the field of Cunaxa, and that among the prizes given to the victors were "golden flesh-scrapers." Not even a brush equals in efficiency the scraping with some metallic instrument, like a dull paper-cutter.

We should recommend, therefore, for fetid feet, that the sufferer should soak the feet in hot water, and scrape them well, every night, until the nuisance is abated; and to keep this up weekly thereafter, with morning ablutions of cold water with no soap, but followed by vigorous rubbing with a coarse towel. This is better than all the salicylated powders or ointment.—*Times and Register.*

IS GERMINATION INDUCED BY MICROBES?

In an article appearing in The Microscope, Dr. Henry Thimer sets forth that in his estimation he has discovered a specific microbe, a micrococcus, which, entering into the seed cells, produces a special ferment which is instrumental in germination. This microbe is provisionally called Micrococcus germinatus. The idea that

microbes are instrumental in promoting the germinative process is not entirely a new one, the author himself quoting Goodale (Physiological Botany) as saying: "It is said that in soil that has been completely sterilized, that is, freed from microbes or germs, seeds provided with all other requisites for germination will fail to sprout. These experiments by Duclaux have not been repeated by other observers." Thimer asks himself, Do these microbes, by working directly on the starch grains, transform them into soluble matter, or do they perform this indirectly by developing the ferments to digest the starch grains?

MEDICAL CHEMISTRY.

MERCURY SALTS AND IODINE COMPOUNDS.

The action of the light on mixtures of salts of mercury and compounds containing iodine have been more fully investigated by George Roe, the results of which he reported to the Chemists' Assistants' Association of London. The author finds that pretty nearly all the mercury salts are decomposed in the light by iodides and iodine compounds, such as iodoform, iodol and soziodol, giving rise to scarlet discoloration, or, in a few instances, to the liberation of iodine. Green, blue or amber glass containers fail to arrest this action, so that such mixtures must be kept in absolute darkness.

IDENTITY REACTION OF PHENACETINE.

W. Autenrieth and O. Hinsberg have recently published a paper on phenacetine and certain of its derivatives in the *Archiv d'Pharmacie*, vol. ccxxix., page 456, in which they first communicate a new identity reaction of the substance, and afterwards give the results of their investigation into the nature of the product of this reaction, and into its constitution. *Identity Reaction for Phenacetin.*—Upon 1 part of finely powdered phenacetin pour 2 parts of nitric acid containing 10 to 12 per cent. of HNO_3 (specific gravity about 1.075), and heat for a short time to boiling. The liquid will assume a yellow to orange color, and the phenacetin, which had at first remained colorless, will at the same time (so far as it is not dissolved) be converted into a nitro compound of an intensely yellow color. When the liquid cools, a further crop of needles of the yellow (or brownish-red) compound crystallizes out. Antifebrin and antipyrine remain unaffected when treated in this manner. If concentrated nitric acid is used, however, antifebrin is colored yellowish-red, and antipyrine yields a red solution. The melting-point of the characteristic yellow derivative of phenacetin, which was subsequently recognized as *mononitrophenacetin*, or $C_6H_3.OC_2H_5(4).NO_2(3).NHCOCH_3(1)$, is at about 103° C.

SOUTH AFRICAN ACACIA GUM.

The Acacia horrida, or "Doornboom," which yields a considerable part of the gum arabic brought upon the English market from South Africa, is one of the most widely distributed forms of vegetation in that part of the globe. A recent account of the economic products of German southwest Africa furnishes some particulars of the collection of the gum in the colony. The gum can only be gathered in the dry season, when the collection is much impeded by the want of drinking water and of laborers—the whole colony of German southwest Africa, a country as large as England and Wales, having only about 24,000 inhabitants. The value of the gum in the interior is about 50 per cent. of the price it realizes on the London market. The cost is increased by 20 per cent. by the transportation to the coast, by another 40 per cent. for carriage from the coast to Cape Town, and again by 40 per cent. for freight from that port to England. The bark of the tree is a valuable tanning material, hence the tree is frequently cut down altogether when its gum is collected.

SALICYLATE OF PHYSOSTIGMINE.

Chemical handbooks direct this salt to be made by dissolving 2 parts of physostigmine and 1 part of salicylic acid in 30 parts of boiling water, and to set the solution aside in a dark place so that crystals may form. There is this difficulty, however, that the free alkaloid physostigmine (or eserine) is exceedingly prone to be converted, under the influence of air and light, into rubeserine, which has a red color. Birkenwald advises (*Pharm. Zeitsch. f.*

Russl.) the following method by which the salicylate may be prepared in colorless crystals: Dissolve sulphate of physostigmine in water, add sodium bicarbonate in excess, shake with several portions of ether in a separator, and filter the united ethereal fractions into a beaker into which some ether containing the calculated quantity of salicylic acid had previously been put. The salicylate of physostigmine will separate in crystals, is then transferred to a filter, washed with ether, and dried in a dark place in vacuo.

NEWS AND MISCELLANY.

PRACTICAL TEACHING OF MIDWIFERY.

Additional provision has recently been made for the teaching of midwifery in connection with the University of Melbourne, Victoria. The University lecturer on diseases of women has been appointed an honorary medical officer of the Women's Hospital, and a ward in the midwifery department has been placed at his disposal. Further, a day has been fixed upon which he will see out-patients, and he has been allotted three beds in the infirmary department. It may be hoped that the arrangements for teaching the subject will be carried out on a thorough and, we may add, antiseptic system. The arrangements which were lately described in the "Notes on Paris Hospitals" in the *British Medical Journal*, at the Hôpital La Charité, and the installation for isolation and disinfection devised by Dr. Budin will serve as a recent and well-thought-out model. We understand that similar arrangements on a large scale are in progress at St. Mary's Hospital, London.—*Ex.*

FIRE-PROOFING FORMULÆ.

While it at present is impossible to make combustible materials absolutely fire-proof, yet it is practical to apply to them substances which will greatly retard their combustibility. The following formulæ will be found useful for curtains, theatrical scenery, decorations and other tissues that will absorb liquids. For light tissues: Ammonium sulphate, 16 pounds; ammonium carbonate, 5 pounds; sodium fiborate, 4 pounds; boric acid, 6 pounds; starch, 4 pounds (or either dextrin or gelatin, 1 pound); water, 25 gallons. The salts are dissolved in a part of the water, the starch or its substitutes in another portion by heat, and mixed; then the goods may be immersed in them, dried and calendered or ironed. For curtain materials, theatrical decorations, wood, furniture, use ammonium chloride, 30 pounds, in the same quantity of water, and add chalk of very fine quality to make a thin paint, and apply warm.—*Ex.*

A CURIOUS LAW SUIT.

A novel action for damages is reported to be pending somewhere in the German Empire under somewhat curious circumstances. A nurse allowed skin grafts to be snipped from her lily-white arm in deference to the wishes of the patient and the request of the surgeon. Unfortunately, the wound did not heal, as might have been anticipated, but proved the starting point of cellulitis, causing great suffering, permanent disfigurement, and some loss of function. The nurse consequently feels aggrieved, and claims damages from the surgeon, but the damages, if any, would seem to be due from the person on whose behalf the plaintiff consented to create the solutions of contumely in her cutaneous envelope.—*Med. Press.*

PASTEURISM AT MILAN.

On July 1st, 1889, a Pasteur institute was opened at Milan in connection with the Ospedale Maggoire, under the direction of Dr. Remo Segré, who had studied the details of the method at Paris under the guidance of M. Pasteur himself. The report of the first two years of work done in the Milanese Institute, which has recently been published, shows that 238 patients have been treated during that time, of whom 108 were bitten by animals experimentally proven to be rabid, and 121 by animals certified to have been so by medical practitioners and veterinarians. Nine cases are returned as "doubtful." Besides these, 61 persons applied for treatment who were proved not to stand in need of it. Of the 238 patients treated, 4 died, 2 of whom belonged to the first class (in which the proof of rabies was experimental), and 2 to the second (in which the disease was proved by veterinary certificate). All the four cases died after the

completion of the treatment, two "a few," one 17, and one 63 days after it. In 232 cases the animal which inflicted the bite was a dog, in 6 a cat. Dr. Segrè uses a syringe of the capacity of 2½ grammes, and employs a whole centimetre of medulla for each person to be inoculated, even in the case of young children. He thus obtains an emulsion of greater density, and therefore, he believes, "richer in curative principles and more active." In a total of 5,386 injections made on 238 persons, he has only twice seen the operation give rise to a small abscess.—*Brit. Med. Jour.*

SNAKE BITES.

Sir Joseph Fayrer, in a lecture at the Victoria Institute on "The Venomous Snakes of India and the Mortality Caused by Them," remarked that the chemistry of snake poison had been studied a good deal of late, and it was shown to be a most virulent poison, which might neither be sucked from a bite nor swallowed with impunity. Many antidotes had been reported beneficial, but experience showed that so far no physiological antidote to snake virus was known, and that when the full effect was produced remedies were of little avail. When, however, the poison had entered in smaller quantities, medical treatment might be of service. The cobra, the most formidable of the Indian snakes, was to be found all over Hindustan, and was equally dreaded and fatal wherever met with. There were many other species which were also most destructive to life—notably, the krait, the kupper, Russell's viper, the hamadryas, and the raj-samp. The mortality from snake bite in India was very great. The average loss of life during the eight years ending 1887 was 19,880 human beings and 2,100 head of cattle yearly. Throughout India in 1889 there were 22,480 human beings and 3,793 cattle killed by snakes, while 578,415 snakes were destroyed at a cost of 23,556 rupees. In 1890 there were 21,412 human beings and 3,948 cattle killed, while 510,650 snakes were destroyed at a cost of 19,004 rupees. The average result for all the provinces showed a mortality of one to every 10,155 of population in 1890, as compared with one to every 9,673 in 1889. To reduce this annual loss of life, it was necessary to make known the appearance and habits of the poisonous snakes and to institute proper rewards for their destruction. Until some measures were more uniformly resorted to, there would be no material diminution in the loss of human life from snake-bite, which could not now be rated at less than 20,000 annually. It was satisfactory to find that the Government of India were insisting upon measures having for their object the destruction of snakes; but he feared that the proposal to cut down and clear away the jungle in the vicinity of villages could hardly be expected to produce the desired effect. He would suggest that a reward should be given for each poisonous snake killed.—*Brit. Med. Journ.*

SOCIETY MEETINGS DURING MAY.

Kentucky State Medical Society, May 1st, at Louisville; State Medical Society of Kansas, May 3d, at Fort Scott; Ohio State Medical Society, May 3d, at Cincinnati; Wisconsin State Medical Society, May 4th, at Milwaukee; Michigan State Medical Society, May 5th, at Flint; Nebraska State Medical Society, May 10th, at Omaha; Indiana State Medical Society, May 12th, at Indianapolis; Illinois State Medical Society, May 17th, at Vandalia; North Carolina State Medical Society, May 17th, at Wilmington; Medical Association of Missouri, May 17th, at Pertie Springs, Johnson Co.; State Medical Society of Pennsylvania, May 17th, at Harrisburg; Iowa State Medical Society, May 18th, at Des Moines; Connecticut State Medical Society, May 24th, at New Haven; Association of American Physicians, May 24th, at Washington, D. C.

ASSOCIATION OF AMERICAN INSTITUTIONS FOR IDIOTIC AND FEEBLE-MINDED PERSONS.

The sixteenth annual session will be held at the Pennsylvania Institution for Feeble-Minded children, Elwyn, Penn., (Dr. I. N. Kerlin, Supt.) commencing Tuesday, June 14th, 1892.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN.

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

THE MOST POWERFUL BACTERICIDE AND PUS DESTROYER
ENDORSED BY THE MEDICAL PROFESSION.
UNIFORM IN STRENGTH, PURITY, STABILITY.
RETAINS GERMICIDAL POWER FOR ANY LENGTH OF TIME.
TAKEN INTERNALLY OR APPLIED EXTERNALLY WITH PERFECT SAFETY.

Send for free book of 72 pages giving articles by the following contributors:

DR. JOHN V. SHOEMAKER, of Philadelphia, Pa. Professor of Materia Medica in the Medico-Chirurgical College of Philadelphia. "Peroxide of Hydrogen." *Materia Medica and Therapeutics, with especial reference to the Clinical Application of Drugs.* Vol. II., page 681.

DR. EGBERT H. GRANDIN, Obstetric Surgeon New York Maternity Hospital, Infant Asylum, etc. "Peroxide of Hydrogen in Gynecology and Obstetrics." *The Times and Register* of Philadelphia, Pa.

NOTE.—Avoid substitutes—in shape of the commercial article bottled—unfit and unsafe to use as a medicine.

Ch. Marchand's Peroxide of Hydrogen (Medicinal) sold only in 4-oz., 8-oz., and 16-oz. bottles, bearing a blue label, white letters, red and gold border with his signature. Never sold in bulk.

PHYSICIANS WILLING TO PAY EXPRESS CHARGES WILL RECEIVE FREE SAMPLE ON APPLICATION.

PREPARED ONLY BY

SOLD BY LEADING DRUGGISTS.

Laboratory, 28 Prince Street, New York.

BAKER'S EMULSION

WITH HYPOPHOSPHITES OF LIME AND SODA.

Among many points in which this preparation excels are:

1st—In quality of the Pure Oil used in its composition, being the finest Norwegian, of a special manufacture, receiving the highest prizes at late European Expositions.

2d—In the Proportion of Oil it contains.

3d—In mode of manipulation and thorough incorporation, rendering it Permanent and Palatable, and of proper consistence, about that of Rich Cream.

4th—In Size of Bottles, containing 16 ounces.

Confidence in the merit of our preparation leads us to respectfully ask a specification of our Brand when prescribing.

ESTABLISHED 1830

JOHN C. BAKER & CO., Philadelphia.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

CLINICAL LECTURES.

CARDIO-VASCULAR GRIPPE.*

By H. HUCHARD, M. D.
PARIS, FRANCE.

A CLINICAL LECTURE DELIVERED AT THE HÔPITAL BICHAT.

Gentlemen :—I have, in a previous lecture, described the different manifestations of cardiac grippe, especially with reference to the action of the poison upon the endocardium, the pericardium and the myocardium. I have not, however, as you will see, exhausted this interesting subject, and I have endeavored to show you that in this disease, the nervous system, more than in any other infectious disorder, is profoundly affected.

MEDULLARY AND VAGO-CARDIAC GRIPPE.

The grippal poison acts upon the nervous mechanism of the heart through the medulla oblongata and the pneumogastric nerves, the functions of which are often greatly disturbed. I will not speak of the intra-cardiac ganglia, the normal anatomy of which is more or less obscure, and the lesions or functional disorders of which, likewise, belong generally to the domain of simple hypotheses.

I have for a long time been struck, especially during the epidemic of 1889-1890, with the lack of concordance in certain grippal pneumopathies existing between the relative benign character, the slight intensity of the lesions, and the gravity of the dyspnœic symptoms. Thus you have observed patients presenting only a few sub-crepitant râles over the chest succumb to an acute attack of asphyxia. At other times, these signs have accompanied pulmonary congestions of hæmoptoic form, attended with true and quite abundant hæmoptysis, which have terminated in death of the patient within a few hours. Still in another class of cases, the pulmonary congestion is slow in its development ; it is sub-acute, resisting, during weeks, all therapeutic treatment. Finally, you have seen the occurrence of a super-acute œdema of the lung accompanied with a kind of albuminous expectoration and a most dreadful dyspnœa to which patients rapidly succumb.

In the course of these various complications, the pulse is sometimes unusually rapid, or, on the contrary, abnormally slow. Again, in certain cases, the gastric phenomena (incessant vomiting, acute dilatation of the stomach, etc.) exhibit a most serious character. The three branches of the pneumogastric are affected, and it is not enough to say with Vovart, that the grippe is particularly characterized by "a neurosis of the vagi," it must be said especially that these nervous manifestations are of a paralytic character. In influenza, let me repeat, the pneumogastric nerves appear as if they were severed, and thus the various congestive phenomena of the lung may be explained, phenomena which I have spoken of as "pulmonary paralysis." These conditions were recognized by Graves, and I, myself, have studied them under the name of *bronchoplegia*. In these cases patients die from being literally asphyxiated, but they may likewise succumb very rapidly under various symptoms of heart paralysis, of *cardioplegia*, since the cardiac branches of the vagi are the ones principally affected.

The disease, whose poison is carried to the whole nervous system, may particularly alight upon the medulla oblongata. This *bulbary* or *medullary* form is quite frequent. I called attention to this point three years ago, and thereafter other

*See issues of the Reporter of April 9 and 16, 1892.

authors have published cases similar to those I, myself, have described. Lately, Kelsch and Antony (*La Grippé dans l'armee Française* in 1889–1890) have said that the peculiar affection of the medulla is not of rare occurrence in the Army, and that it has usually made itself manifest by symptoms of syncope and lypothemias. I have, myself, observed a medullary phenomenon *par excellence*, that is, the Cheyne-Stokes respiration, and this in the absence of all renal lesions. Finally, we can refer to the medulla many cardiac symptoms dependent upon a disturbance of the functional activity of the vagi, such as *tarchycardia*, *brachycardia*, certain phenomena of *cardiac collapse*, *cardiactasis*, and *cardioplegia;* those dependent upon paralysis of the lungs and bronchi (*bronchoplegia*), and the œdemas, or vagoparalytic pulmonary congestions; as also certain super-acute emphysemas. It is important to be acquainted with this medullary form; to this have been due the rapid or sudden deaths reported by almost all the ancient historians of the disease in question.

I have, myself, reported many cases of this nature to the Societè Mèdicale des hôpitaux (*Soc. Méd. des hôpit.*,) January 24, 1890), some of which are as follows: One of our lamented country colleagues died in the following manner: He was suffering from a slight bronchitis; from time to time he would be taken with marked attacks of suffocation, which would be brought on even by slight exertion; the pulse would become accelerated, the patient being threatened, at every moment, with syncope. He died suddenly through failure of the heart, after many lypothemic attacks, without there being anything to announce such a brusque termination. Another patient exhibited simply symptoms of an infectious gastric embarrassment. He died from syncope, notwithstanding that auscultation had revealed nothing abnormal. A man, 60 years of age, had all the symptoms of a gastric trouble, which rapidly assumed an infectious character, and the general prostration was so marked that the attending physician believed it to be the beginning of an enteritis. (I have often showed you, during the epidemics of 1890 and 1891, cases of this grippal *pseudo-typhoids* through which errors of diagnosis have been made). This patient had a cerebral excitement with an irresistible tendency to somnolence; a little albumen was found in the urine, and over the base of the right lung, small, fine râles, indicative of pulmonary congestion, were noticed. Finally, there appeared in a rapid manner, arythmia, and attacks of cardiac intermittence, this latter phenomenon being definitely established later. One night death was imminent; the pulse was weak, compressible, filiform, and became better only after many hypodermatic injections of ether and caffeine. On the following night, the patient was threatened with cardiac collapse. During a whole hour the pulse was weak and could hardly be felt under the finger, the fluttering condition of the heart being quite noticeable; the extremities became cold and cyanosed, the skin covered with a cold sweat, and the patient was thrown into a state of lypothemia and continued somnolence. In one word, it seemed as if death would occur at any moment, and, therefore, I gave, one after another, five subcutaneous injections of ether and caffeine. An hour later, the pulse recovered its force and regularity, and by next morning, all these symptoms had disappeared. On the reappearance of these serious symptoms the injections were resorted to with the same happy results.

You see, then, that therapeutics is not entireless powerless, and in order to treat such symptoms with higher probabilities of success, it becomes necessary that we should be thoroughly acquainted with them.

CARDIO-VASCULAR AND VASCULAR GRIPPE.

a. The *pulse* often presents that character which I have spoken of as unstable. Such phenomenon consists in this: From the moment that the patient passes from the horizontal to the vertical position, that is when he sits upright, the pulse becomes accelerated, going up as high as 80, 120 and even 130 per minute. This is a sign of cardiac weakness and of depression of the arterial pressure, and is especially observed during convalescence. It must not, however, be confounded with the unsteady pulse described by Graves in the following terms: "The pulse rarely exhibits identical characters. You will find it rapid and hard; 6 hours later it will be rapid and soft, and later still, after 6 or 8 hours more or less, it will show a normal frequency;

but by the following morning it will have become quick and jerky . . . . But the most remarkable fact is that towards the end of the malady, the pulse sometimes becomes full, strong and vibrating, and this is observed upon individuals who have suffered for whole weeks."

In the course of the various pulmonary manifestations (pneumonias, bronchopneumonias, etc.) the pulse frequently exhibits a rapidity proportionate to the height of the febrile movement. Yet, at other times, an absolutely opposite phenomenon is observed, the cardiac beat being relatively slow, which is in great part due to the medullary or bulbary disturbances.

This relative *brachycardia* did not escape the sagacious observations of older authors. Thus in the epidemic of 1837, according to Landau, "the pulse, ordinarily large and full in this disease, was small and slow, and except in two patients in whom it attained a rapidity of 82, it did not go beyond 72; generally it varied from 60 to 68." Valleix, who has generally held a contrary opinion, is forced to admit that "the pulse appears to have less amplitude . . . . Its acceleration does not, in the majority of cases, bear any relation to the violence of the febrile symptoms." This is a fact which has been noticed in quite a large number of cases, and which pleads in favor of the action of the grippal poison on the pneumogastrics.

From this point of view there is one disease which resembles influenza, and that is, typhoid fever, characterized, as you well know, by a relative slowness of the pulse, which is at the same time a favorable prognostic sign. Typhoid fever, likewise, resembles influenza in its action upon the arterial contractility, and, similarly, in the considerable diminution of the vascular pressure.

b. Condition of the arterial pressure.— You already know that typhoid fever is characterized by a low arterial pressure, this being one of the chief causes which produce in this disease the formidable syndrome known as *embryocardia*. Again, my numerous researches regarding the state of the arterial pressure, have shown that ordinarily there is in influenza a considerable diminution (*Soc. Méd. des Hôpit.* March 14, 1890); hence, embryocardia is not rare in this affection.

This embryocardiac syndrome studied by Stokes under the name of "fœtal rhythm of the heart-beat" but which does not appear to comprise its pathogeny nor its prognostic importance, is due, according to my investigation, to the extreme lowering of the arterial pressure and to the weakness of the heart. It is characterized by 3 fundamental symptoms: 1, *tachycardia*; 2, equalization in the duration of the two pauses; 3, a similarity in the thrill of the two sounds. Thus, the embryocardiac beats resemble those of a pendulum, or those of a fœtal heart. Again, the appearance of this sign has a great prognostic importance, as it may sometimes announce the fatal termination of the malady in a longer or shorter period, if a remedy is not promptly given. The best medication consists in the administration of remedies that constrict the blood-vessels and elevate the pressure, such as ergotine and caffeine. I have observed this syndrome in many cases, during the course of the disease and even during the period of convalescence. It will be sufficient to report the following instance: A patient, 51 years of age, suffering from the grippe, was suddenly attacked by cardiac symptoms: pulse feeble, almost imperceptible, and difficult to count (160 per minute); sensation of retro-sternal constriction and constant oppression; cyanosis of the hands and extremities; coldness of the surface; a precipitated action of the heart, the beats, 200 per minute, being equal in thrill and intensity, separated by the pauses of absolutely equal duration (embryocardia). The patient died 40 hours after the onset of these symptoms; there was no elevation of the temperature; on the contrary, there was a quite marked tendency to a diminution of the bodily heat.

Embryocardia is sometimes the precursory phenomenon of *cardiac collapse* to which the patients rapidly succumb.

c. Grippal arteritis and phlebitis. Do the arteries suffer directly under the influence of the grippe, in other words, is there such a thing as a *grippal arteritis*? The question remains *sub judice*. I will, nevertheless, bring to your notice the fact that in an autopsy I have found an obliterating inflammation of the coronary arteries. On the other hand, Rendu has recently reported a case of gangrene (*Soc. Méd. des Hôpit.*, January 15, 1892) of the extremities, after an attack of the grippe. But, as has been observed by Netter an arteritis may be found in the neighbor-

hood of a clot, and here again we have an analogy with the condition met with in typhoid fever.

A fact which I have observed and which was not unrecognized by the older historians of the disease, is that pertaining to the great frequency of *cerebral hæmorrhages* occurring during the course of an epidemic. I do not pretend to say that the grippe *per se* is capable of producing this accident; but I cannot help believing that the malady in question enhances the rupture of the miliary aneurisms of the brain.

Grippal phlebitis is better demonstrated, of which I, myself, have observed four cases. In this respect I will recall the case of double phlebitis of the inferior extremities occurring in a boy-patient, following an attack of the grippe, and which was complicated with serious symptoms of pulmonary embolism. My colleague, Ferrand, has, likewise, reported two cases of phlebitis of the lower extremities, this condition occurring after an attack of influenza (*Soc. Med. des Hopit.*, March 14, 1892).

d.–Action of the grippe on cardiopathies. This is another category of the action of the disease, that deserves your most serious attention. I have often spoken to you about the chronic maladies aggravated by influenza, and of the kind and amount of aggravation of such maladies. I have shown you a large number of valvular affections of the heart in which the rapid aggravation could be dated from the very day that patients were attacked by the grippe. From that time, the cardiopathy, compensatory or latent, rapidly arrives at a hyposystolic, and at the same time at a definite asystolic period. An explanation of this is found in the tendency of the grippe to diminish the arterial pressure. Again, you know that the lack of compensation in diseases of the heart is due, in great part, to the lowering of the arterial pressure, and you can understand why influenza, bringing about an asystolic condition, rapidly aggravates a pre-existing cardiopathy, and it does so more readily than through an influence on the nervous mechanism of the heart

This aggravating influence is also exercised on arterial cardiopathies. In three cases of angina, the sternocardiac crises were quite frequent and severe. In one case, laboring under an interstitial nephritis, an attack of influenza produced a rapid fatal termination through a sub-acute œdema of the lungs. In one word, arterial cardiopathies are evolved with marked rapidity, and appear as complications of arythmia, cardiac intermittance and cardiac asthenia. I have seen a large number of cases of arterial sclerosis of the heart, which, while latent from a symptomatic point of view, were made manifest after an attack of influenza under a persistent arhythmic form. On the other hand, in the absence of all lesion of the myocardium or of the valvular apparatus, or by virtue of a simple functional affection, the arhythmia may appear suddenly during the course of the malady under consideration or during the period of convalescence, remaining then as a permanent symptom.

An interesting case has been reported by H. Blanc (L'arteriosclerose en general et les scleroses vasculaires dans l'armee, *Arch. de Méd. Militaire*, 1891) which sustains what I have said regarding the aggravating influence of the grippe on arterial cardiopathies. It is as follows: A soldier exhibiting all the appearances of a perfectly healthy individual, suffered an attack of grippal broncho-pneumonia. After his recovery he continued to suffer from dyspnœa; on examination there was found a marked systolic murmur over the third intercostal space of the right side. At first it was thought to be a simple extra-cardiac murmur; but three months afterwards, the diagnosis of an arterial cardiopathy was made. Here was a patient without any renal or pulmonary trouble, and in whom the orifices of the heart were healthy; the symptoms came on after an attack of the grippe and the slightly perceptible hypertrophy noticed at first, had become more and more marked. Here, then, the relation of the cardiac affection to the grippe was quite clear.

However, it is only late, that is, after a year or two or perhaps many years, that cardiac symptoms following an acute infectious malady are made manifest. This shows that the effects do not always immediately follow the causes which produce them. If after an attack of influenza, typhoid fever, small-pox, scarlatina, etc., you do not find any trouble in the heart during the march of the disease or during the period of convalescence, you must not, however, neglect to practice cardiac auscultation. The lesions following these various affections may remain latent for a

long time; they may require months or even years to make themselves manifest; and many times you may and will meet with aortic insufficiencies the ætiology of which you are at loss to account for, and this because you have failed to recognize the influence that any one of the infectious diseases referred to may have exercised.

If coronary endocarditis of grippal origin really exists, of which I have had occasion to show to you one example, you can understand why it remains latent until it alights upon the cardiac muscle to produce degeneration. You would be wrong in dating from this day the appearance of the cardiopathy, and you see the importance of not confounding the *apparent* with the *real* beginning of a disease. Inflammation of the coronary arteries may commence and has commenced during the march of the affection or during the period of convalescence from the grippe; the lesion progresses in a quiet manner undetected by your ear; and the consequent degeneration of the myocardium is at last made apparent by a marked symptomatology. Bouchard has remarked: "The infectious diseases produce often tardy consequences. While the pathogenic germ may be destroyed, the disease is not at an end; man continues under its influence, and after a long time, it appears in certain tissues and apparatuses through lesions which are the expression of a tardy disturbance of nutrition brought about by an infectious malady."

e.—Grippe and rheumatism.—According to my observations, rheumatic troubles are of frequent occurrence during and after epidemics of influenza. This fact has not escaped the notice of ancient authors and thus Lancisi who has wrongly assimilated, so to speak, the two affections, has given to influenza the name of *rheumatic fever.*

I have observed two cases in which an acute articular rheumatism was developed during the course of influenza and during the convalescence from the disease. In the first case I noticed the coming of an endopericarditis which could be attributed to rheumatism and not to the grippe. This is a source of error to which I desire to call your attention; you must not attribute to the grippe an endocarditis which is dependent upon a rheumatic affection. Let me remind you of the fact that influenza, more than upon the endocardium and pericardium, it exercises an action on the nervous mechanism of the heart.—Translated from *Le Bulletin Medical*, March 13, 1892.

ALLEGED SYPHILITIC INFECTION BY INSTRUMENTS.

BY G. FRANK LYDSTON, M. D.,
CHICAGO.
PROFESSOR OF DISEASES OF THE GENITO-URINARY SYSTEM AND SYPHILOLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS.

Gentlemen:—The first case which I present to you this morning is one of unusual interest, involving as it does certain interesting clinical features of syphilis and some points in what might be termed the jurisprudence of syphilis.

The patient, a woman of about 40 years of age, who, as you see, is a stout, healthy looking individual, was referred to me by a prominent physician as a case of syphilitic infection probably due to unclean instruments in the hands of a respectable practitioner of this city. The woman gives a history which, taken in connection with her present condition, most effectually proves the error of the charge against the doctor by whose unclean instruments the case was supposed to have been infected. This is a matter of congratulation, as the patient herself has apparently been very acrimonious and disposed to make trouble for her physician.

The history of this patient is as follows: Six weeks ago she consulted her doctor for treatment for a sore throat, which had then lasted about a week. The doctor, she claims, told her that she had pharyngitis and enlarged tonsils and made some applications to her throat, using as she expresses it "an old brass thing," which hurt her tongue and made it sore for several days. One week later she says she noticed an eruption upon her body. She denies any local trouble and declines any examination. She says that she has had absolutely no exposure to possible venereal infection. On examining the face, you will notice a distinct erythema involving the nose, the inner aspect of the cheeks, the lips and the chin. On palpation I find this erythematous area to be slightly raised from infiltration, the skin

being slightly stiff to the feel. There is no tenderness and no heat in the parts. Here and there upon the face we observe an eruption of papules, some few of which are scaly. I find upon the scalp papulo-pustular and papulo-crustaceous syphilides. Just at the roots of the hair and extending down for a few lines upon the forehead you will observe a crown-like and symmetrically arranged series of distinct rows of papules, presenting the characteristic livid red color of the syphilide. Upon the neck and chest we observe a fading macular eruption, the *roseola syphilitica*, interspersed with papular and papulo-squamous lesions. Upon the palms are found scaly papules, and the patient claims that similar lesions are present upon the soles of her feet. We will now proceed to examine the mouth to see if we can find anything suggestive of a chancre. On careful inspection I fail to find any vestiges of what might be even suspicious of an initial lesion either in the mouth or pharynx, or upon the tongue. I find at the base of the tongue at the point where the patient seems to believe infection occurred, a characteristic mucous patch, in no wise different from a number of others upon the tongue. I observe several rhagades or fissures upon the sides of the tongue. There is a liberal supply of mucous patches upon the buccal mucous membrane and several in the larynx, the tonsil upon the right side containing one of good size. The fauces and pharynx present the characteristic appearance of a syphilitic sore throat. You will notice that the left eye presents a redness of the conjunctiva and the patient claims that it is very sensitive to light, and that she has had considerable pain in and about the eye for several days. I find on examination that the pupil is sluggish in its reaction to light, and that the iris appear a little swollen and cloudy and of a more grayish color than natural. We have, in other words, characteristic evidences of syphilitic iritis. The *ensemble* of lesions in this case presents as pretty a picture of marked early secondary syphilis as could be wished. We will now dismiss the patient and proceed to consider the merits of this case.

To the uninitiated the history of this woman, as she gives it, might seem to have a very important bearing upon the professional skill of the physician whom the patient accuses of infecting her with syphilis. Fortunately for the medical profession,—and sometimes for accused individuals among the laity,—syphilis is a disease which has a very typical and reliable course of evolutionary progression. The fact that this woman has had this eruption for four weeks proves conclusively that the accused physician could not possibly have infected her at the time stated. As this physician had not treated her throat before, his innocence is thoroughly established. Wherever the location of the primary lesion may have been in this woman, said primary lesion must have antedated the appearance of the eruption several weeks; in all probability, at least four, and more likely six or eight weeks. There is little doubt in my mind that the eruption existed upon her body prior to the time she states and was probably present at the time she consulted the physician for sore throat. That sore throat was in my estimation syphilitic, and in all probability the inconvenience that the patient experienced from the use of the tongue depressor at the hands of the physician was due to irritation of the already existing mucous patch upon the base of the tongue. Of course, at this late period there would be little likelihood, even though infection occurred in the manner stated by the patient, of my finding remains of a chancre in the mouth. Still, as the woman has not been properly treated, and there are present in the mouth all of the conditions essential to the protraction of irritation, it would be by no means surprising,—admitting that infection had occurred in the mouth,—for us to find at the present time chancrous erosion or ulceration. If a characteristic chancrous lesion were found, it would show at least that the infection did occur via the mucous membrane of the mouth or tongue according to the situation of the sore. The presence of a chancre wherever found would not, however, change my opinion in the least as regards the date of infection. This woman was probably infected in the good old fashioned way some twelve weeks or so ago.

I wish, gentlemen, to call your attention by means of this pertinent illustration to the necessity in cases of syphilis of obscure origin, or cases in which an accusation is made against a physician of having produced syphilitic infection by means of unclean instruments, of studying carefully the natural history, the characteristic

evolution, so to speak, of alleged vaccinal syphilis. The physiological disturbance incidental to the febrile reaction from vaccinia sometimes brings to the surface dormant syphilitic conditions, and the practitioner performing the operation of vaccination might possibly be given a great deal of annoyance, or even have his reputation seriously impaired by the accusation of having infected the patient by impure virus or an unclean syphilized lancet. If the physician can prove uneqivocally that he used bovine virus, and if he can show that he has performed his scarification with the ivory point itself, he has a pretty clear case, otherwise there is a certain element of insecurity in his position. If immediately following the vaccination, i. e., within a few days or a couple of weeks or so, a generalized eruption occurs, even admitting this eruption to be of a syphilitic nature, it cannot possibly be due to infection during the vaccination, for there is a distinct incubation period following the introduction of the syphilitic poison before the local sore appears, and another apparent period of incubation—the so-called secondary period of incubation, intervening between the appearance of the chancre and the development of a generalized eruption. Within certain limits this division of the evolutionary course of syphilis into periods of some weeks duration is very arbitrary. In order to prove infection at the hands of the physician it must be shown that a local duration or some peculiar transformation of the vaccinal vesicle has occurred, appearing on the average 21 days after the operation of vaccination, this being followed by a period of quiescence of on the average six weeks duration, which period of quiescence is succeeded by general manifestations of syphilis. Then too, the character of the lesions in alleged cases of surgical infection with syphilis is very often significant. If, for example, a child after vaccination, or a patient after a surgical operation, should develop within a few weeks bone or periosteal lesions, or any of the various phases of gummy deposit characteristic of late syphilis, it would certainly throw the case of infection on the part of the physician out of court.

Note.—I have since corresponded with the gentleman whom this woman accused of having infected her by means of unclean instruments. I find that the woman is the proprietress of a disreputable lodging house run for the benefit of *nymphs du pave*, and that while she had no generalized eruption as far as the doctor knows, she was suffering from mucous patches upon the tongue and tonsils at the same time he made his applications. The physician is one of our most competent practitioners.

CONCEALED CHANCROID WITH SLOUGHING.

The next case to which I will call your attention is a young man who has been suffering for some weeks with some trouble with his penis. He states that four or five days after suspicious exposure he developed several small ulcerations, upon the penis apparently from his description situated just back of the corona glandis. Within a few days the prepuce, which was always redundant and retracted with difficulty, became greatly inflamed, and he found that he was unable to retract it. The inflammation and swelling have gone on until to-day you notice that the prepuce is very much elongated and swollen and on pinching it up between the thumb and fore finger, I find that it is quite hard in consistency. Issuing from the preputial orifice, you notice a thick, greenish, extremely virulent looking purulent discharge. On the superior surface of the prepuce just over the glans, you will notice a discolored area in the middle of which there is a ragged, irregular opening. This is the first beginning of sloughing of the tissues of the prepuce. Evidently a spot corresponding to this aperture has become gangrenous and has sloughed away, leaving an ulcerated and sloughed area of tissue behind it. I have no doubt that the test of auto-inoculation would show conclusively if we cared to wait two or three days for this evidence, that we have to deal with here a case of concealed chancroid. The history of the case, however, and the appearance of the parts are sufficient for a diagnosis. Now, the question arises; has this patient true syphilis? Without an inspection of the parts it would be impossible for any one to pass an opinion upon this point. Even upon inspection it might be impossible to say at this early period whether the patient has syphilis or not. I find upon inspection of the groins a well marked bubo upon each side. There is yet no fluctuation, but from the diffuse character of the inflammatory glandular swelling, the dusky appearance

of the skin over it and the extreme tenderness of the part I can safely predict that within a few days suppuration will be evident. I might remark in this connection, gentlemen, that even at this stage of the development of the bubo, there will be found in every one of these cases more or less purulent infiltation. We will not expatiate upon this point at this juncture.

The question arises, what shall we do with this particular case? All of the standard works upon genito-urinary diseases say: Do not do any cutting operation in these cases of concealed chancroid, as infection of the cut surfaces will invariably occur and a huge chancroid of a size proportionate to the extent of the incision invariably result. The question at issue in such cases is, which is the better practice? To allow these chancroids to go on in their course of destruction beneath the swollen and infiltrated phimosed prepuce, or shall we lay the part open to inspection and thus permit free drainage, cauterization and antiseptic treatment? Suppose the incision does become infected, is not the resulting ulceration open to inspection and treatment? And is not its occurrence more than counter-balanced by the increased facility for treating the hitherto concealed chancroids after the operation? This much I may say, the cure of a case of this kind after incision, is a matter of weeks; without incision, it is a matter of months. We have as a rule, only to fear more or less destruction of the prepuce after thorough exposure of the chancroids beneath it by incision, whereas, in case they are allowed to remain concealed serious destruction of the glans penis may occur. Concealed chancroids are a standing invitation to phagadena and gangrene and serious destruction of penile tissue. Despite the doctrines inculcated by our most eminent authorities upon venereal diseases, I believe that the proper treatment for concealed chancroids is to lay the prepuce open upon the dorsum after the part has been antisepticized by means of the peroxide of hydrogen, followed by a solution of bichloride of mercury 1-1000, injected beneath the prepuce. Any existing sores are then to be cauterized and the parts dressed with iodoform. When upon exposure of the chancroids they are found to be located upon the prepuce and not upon the glans penis, a complete circumcision should be performed, provided we can thereby remove the chancroids. This, however, should not be done until the parts have been thoroughly deluged with antiseptic solutions and the chancroids thoroughly cauterized. I have operated upon such cases in this manner and had them heal by first intention, and I cannot say that I have ever operated upon a case where I had occasion to regret it. I must say, however, that I have on several occasions been unjustly criticised by some of my professional brethren who are adherents to the dogma of infallability of authorities and into whose hands cases upon which I had operated subsequently fell. If phagedena does not attack these cases after the operation they do perfectly well, and phagedena is much less likely to attack the parts after than before an operation.

I will proceed in this case to lay the prepuce open as I have directed. I find on slitting it open upon a director several chancroids upon the prepuce itself. These I will cauterize thoroughly with carbolic acid. I will then trim off the ragged prepuce and thus make a complete circumcision. I will now, after stitching the cut edges together, apply powdered iodoform with a small iodoform gauze roller bandage. The wound may possibly not heal by first intention, but if not, the parts will be in much better condition for healing than prior to the operation. It would not surprise me at all to find within a few days on redressing the part that the incision has healed by first intention.

TRANSMISSION OF TUBERCULOSIS BY THE SEMINAL FLUID.

At a meeting of the Society of Anatomy and Physiology of BORDEAUX, SOLLES (*Journal de Médecine de Bordeaux*, 1892, No. 5, p. 52) reported the results of experimental inoculation of two guinea-pigs, the one with the fluid expressed from the testicle of a tuberculous subject, and the other with the spermatic fluid obtained from the seminal vesicle of another tuberculous subject. In the first, the induration at the site of inoculation slowly disappeared, without involvement of adjacent glands, and the animal recovered. In the case of the second guinea-pig, fatal general tuberculosis developed. The evidence, in so far as furnished by a single case, points to the hereditary transmissibility of tuberculosis.

COMMUNICATIONS.

SHALL PHYSICIANS BECOME SALES-AGENTS FOR PATENT MEDICINES?*

By SOLOMON SOLIS-COHEN, M. D.
PHILADELPHIA.

Section 4 of Article I of the By-laws of the Philadelphia County Medical Society reads as follows:

"Any physician who shall procure a patent for any instrument of surgery, or who sells or deals in patent remedies or nostrums, or who shall give a certificate in favor of a patented or proprietary remedy or patented instrument, or who shall enter into an agreement with an apothecary to receive pecuniary compensation or patronage for sending his prescriptions to that apothecary, shall be disqualified from becoming or remaining a member."

Article VIII of the By-laws of the Philadelphia County Medical Society, accepts as an integral portion of those by-laws, the Code of Ethics of the American Medical Association.

A section of that code of ethics treats "Of the Duties of Physicians to Each Other and to the Profession at Large." Article I of that section sets forth "Duties for the Support of Professional Character." Section 3 thereof condemns open or underhand advertising as "derogatory to the dignity of the profession." "These," it says, "are the ordinary practices of empirics, and are highly reprehensible in a regular physician." Section 4 continues:

"Equally derogatory to professional character is it for a physician to hold a patent for any surgical instrument or medicine, or to dispense a secret *nostrum*, whether it be the composition or exclusive property of himself or of others. For if such nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality, and if mystery alone give it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice. It is also reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines, or in any way to promote the use of them."

To the clearness and force of this dictum nothing can be added. Its wisdom and its justice are beyond dispute.

It is unfortunately true that much of our therapeutics is as yet empirical. Nevertheless the best endeavors of the true physician are directed toward establishing a rational basis for that which experience has proved to be beneficial; toward obtaining scientific data by which to make progress to a therapeutics not empirical; and toward eliminating from the traditional heritage of the profession such measures as may have had their origin in superstition or mistaken observation. To use preparations of unknown composition; to use mixtures of innumerable substances, some directly opposed to each other; to use even rational and known combinations of which the ingredients and proportions have not been adjusted to the indications and conditions of the individual case—are certainly not scientific methods or practices likely to advance rational therapeutics.

That much of the flavor of the mystery and witchcraft that at one time appertained to the practice of the healing art should have survived among the vulgar, is only a phenomenon to have been expected in the natural course of social evolution. Hence it is that homœopathy, and mind-cure, and patent medicines, have so powerful and so profitable a hold upon the purses of the community, and this not alone among the ignorant and the unlettered. It is a notorious fact that the clergy—presumably educated and intelligent men—are among the most prominent and persistent givers of testimonials to the virtues of advertised nostrums, and medical men and medical journals have long made the religious press a target for satire and invective, because of the hold that the advertising quack has secured upon its columns.

In an address to the Medical Society of the State of Pennsylvania at its last meeting, in calling attention to the alliance betweeen the secular press and the empirics and nostrum-venders, I felt justified in saying that the publishers of magazines and newspapers that allowed themselves to advertise the curative virtues of this or that ready-made preparation or alleged remedial measure, to be applied indiscriminatingly to all cases--whether of one disease or of many diseases—were accessories to a crime against the unfortunate and the

*Read before the Philadelphia County Medical Society, April 27, 1892.

helpless; not alone because of the money filched from the pockets of those deluded by the false promises held out to them; not alone because of suffering unrelieved and lives deprived of their chance for prolongation; but in many instances because of the disease and suffering and death directly produced by the poisonous compounds or noxious gases administered to any that chose to purchase. If such criticism was justified—and who is here that will deny its truth?—if such criticism was justified when applied to those who make no pretence of special knowledge or of devotion to a noble art—to those whose object is solely and avowedly commercial—what language remains to characterize the action of medical journals that permit the insertion in their columns of advertisements such as these that I pass around? *Journal of the American Medical Association*? What words of condemnation are strong enough for the physician that permits his name to be associated with these devices of the devil?

The frankly unscrupulous patent-medicine vender, the maker of "Safe-cures," or "Temperance Bitters," or "Sure-Specifics," is at least to be commended for what, to paraphrase a remark of Senator Benjamin Harrison's, may be termed his "bold brutality." His allegations of philanthropic motives are not intended to be believed; they deceive no one—they are the recognized *ad captandum* devices of the clever advertiser—and, in the sale of his wares, there is no pretence of examination, or of diagnosis, or of prescription based on diagnosis.

Far more iniquitous and far more dangerous to society is the wily manufacturer that advertises "to the profession only." Whether he ostentatiously holds secret the composition of his nostrum, or whether with pretended frankness he describes it with an appellative that means nothing, or publishes a formula that cannot be carried out, his object is the same; he seeks to make the physician's the hand whereby he may reach pockets shut from the coarser methods of the Warners, the Pinkhams, and the Jaynes; for, after all, it is the minority that can be deluded by the flaring posters of "Wizard Oil," or the lying testimonials of "Tonic Vermifuge." When a sick man applies to a physician, thinking that thereby he will secure the benefit of special knowledge brought to bear upon the conditions of the individual case, entrusting to the conscience of his medical adviser his health and his life, he is entitled to the skill and the thought for which he pays, and that he deems himself to be receiving. He certainly deserves better treatment than to be handed over to the mercies of "antikamnia," or "febricide," or "quickine," or "gleditschine," or "Freligh's tablets," or "Listerine," or any other of the unholy crew. If such is to be his fate, let him have the satisfaction of buying the worthless or poisonous stuff direct, without the sham of a professional consultation, and without paying a purchaser's commission to the medical sales-agent.

At the coming meeting of the State Society I purpose offering the following resolutions, for which I ask the support of this Society:

Resolved, That the Medical Society of the State of Pennsylvania hereby expresses its highest disapprobation of the practice of giving certificates or testimonials to secret preparations alleged to be of medicinal virtue, and calls the attention of the affiliated county societies to the fact that such action on the part of members of the said societies is in derogation of the dignity of the profession, and in violation of the letter and the spirit of the Code of Ethics of the American Medical Association and of this Society.

Resolved, That this Society likewise expresses its disapprobation of the practice of inserting advertisements of secret preparations in the columns of medical journals, such action being an insult to the intelligence of the profession, and a degradation of journals indulging therein to the level of the patent medicine almanac. Especially to be condemned is the action of the *Journal of the American Medical Association* in admitting such advertisements.

Resolved, That copies of these resolutions, duly attested by the permanent Secretary, be sent to all county societies in affiliation with this Society, to the American Medical Association, to State medical societies in affiliation therewith, and to the publishers and editors of American medical journals.

On motion of Dr. J. Madison Taylor, the resolutions were adopted as the sense of the Philadelphia County Medical Society, and the delegates to the Medical Society of Pennsylvania were instructed to officially present and support them.

DOES ORGANIC DISEASE OF THE HEART PRECLUDE THE USE OF CHLOROFORM IN PARTURITION? *

BY T. RIDGWAY BARKER, M. D.,

DEMONSTRATOR OF OBSTETRICS IN THE MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA; OUT-DOOR OBSTETRICIAN TO THE PENNSYLVANIA DISPENSARY.

In entering upon the discussion of a subject of such paramount importance to mother, offspring, and obstetrician, one cannot lay too much stress at the very outset upon the axiom that "A good remedy will fail of its effect if not properly administered." This fact must be kept uppermost in our mind if we would avoid fatal results, not due, however, to the employment of the agent, as some would make it appear, but to the lack of attention and care exercised in its administration. That there is a radical difference between surgical and obstetrical anæsthesia (analgesia), goes without saying. If we consider for a moment the stages of anæsthesia, which differ only in the profoundness of the impression—first, sopor; second, stupor; and, third, stertor—we cannot fail to notice that in analgesia one rarely has occasion to carry the effect beyond the first degree (sopor), while in the surgical variety we are obliged to advance beyond this and keep the patient in the second stage, or that of stupor, thus markedly increasing the gravity of prognosis.

In this connection, let us devote a moment's consideration to the progressive effect of chloroform vapor upon the nerve-centers of the cerebro-spinal system, beginning, as it does, at the inferior extremity of the cord, sacro-lumbar, and gradually extending its paralyzing influence upward until it reaches and expends its force upon the medulla oblongata. These well-established clinical observations having been verified by physiological experiment, we are justified in putting them to practical use. What other agent, may be pertinently asked, can relieve—aye, abolish—pain so quickly and safely, yet leave reflex muscular contractility unimpared, as chloroform? Ether and ethyl bromide have found favor with some practitioners, but neither can displace chloroform.

Fordyce Barker states in his writings: "I may say here that I have long regarded chloroform as the best and safest anæsthetic in obstetrics, and that since 1850 I have used no other."

The danger from the employment of chloroform in this department of medicine depends more upon the carelessness with which it is administered than to any toxic effect inherent in it. The four cardinal points to be borne in mind when giving this anæsthetic are: First, plenty of pure atmospheric air; second, liberation of a small amount of the vapor at a time; third, attention to the respiration; and, fourth, frequent observations as to the force and frequency of the cardiac action. That the recorded cases of death have been due in a great measure to saturation of the residual air in the lungs to a fatal degree can scarcely be doubted. A few deep, forced inspiratory efforts will quickly produce such a condition. Withdrawal of the agent under these circumstances cannot prevent the further entrance of the chloroform vapor into the circulation, for it already fills the air-cells. Nor will attempts at artificial respiration prove effectual, since but a small quantity of the residual air can be forced out of the lungs, while that which enters fails to sufficiently dilute the vapor owing to the tardiness of diffusion. Let us not suppose, however, that because we administer to the parturient female small amounts of the drug continuously, therefore no risk is incurred, for experiments directed to solve this important question go to prove that even small doses, when continuously inhaled, tend to produce dangerous, and at times fatal, cardiac exhaustion. Far different is the result when given intermittently, as is the unalterable rule in obstetrics. Should we seek authority for the statement that the dangers from the careful administration of chloroform in labor are too insignificant to warrant its refusal, we have only to turn to the *American System of Obstetrics* to find therein the following: "The danger when chloroform is used only to the extent of mitigating or abolishing pain in childbirth is practically *nil*." Lusk, quoting from Bert's experiments, states "that chloroform might be intermittently administered for an indefinite period with safety." These remarks do not apply to its use in

* Read before the Philadelphia County Medical Society, April 27, 1892.

the third stage of labor, for as is well known, after delivery of the child it is likely to occasion relaxation of the uterus, thus favoring post-partum hæmorrhage.

Offering the above as a preface to my remarks on the judiciousness of employing chloroform when the parturient female suffers from organic cardiac disease, it now remains for us to consider the effect of parturition upon this enfeebled circulatory organ, thereby securing a scientific basis for our conclusions. In the first stage of labor we find the muscular contractions confined to the uterine muscular layers and directed toward overcoming the circular fibres of the cervix, while in the second or propulsive stage not only does the uterus exert its power to the utmost, but also the abdominal and respiratory muscles are brought into action by the will of the parturient in her efforts to expel the fœtus. The diaphragm is forced down and its movements paralyzed by the female holding her breath.

The other respiratory muscles are likewise unable to act, and hence imperfect oxidization of the blood results. As a consequence, the cardiac movements are accelerated, greater resistance is met with in the pulmonary and aortic circulations. Moreover, a tendency exists to venous congestion, as evinced by the hue of her face and swollen veins.

Owing to the excruciating pain experienced when the head passes through the cervix, the parturient is further tempted to make additional muscular efforts, which only augment the difficulties met with. Under normal conditions this strain is of such brevity that it cannot be considered of any importance, but when complicated by disease of the heart it is of far greater gravity. If the condition be one of fatty degeneration due to a previous peri- or myocarditis, resulting in faulty nutrition and enfeeblement of the heart's action, as envinced by weak impulse, venous stasis, confused and irregular sounds, anæmia alike of brain and other organs, with faintness and oppression on the slightest exertion, this interference with circulation and respiration may readily tax its powers too far, and so cause speedy death from paralysis. Here the conditions which pertain in surgical anæsthesia are absent. The indications present are to allay excessive muscular action and respiratory spasm which is threatening the over-stimulated heart.

To allow the female to continue such efforts is to permit her to commit suicide; to warn her to desist is useless when in such agony; while delay is likely to be fatal. How can we overcome this condition of nervous excitement? Can we accomplish it by the administration of chloroform? Yes; of the two evils, for we must acknowledge there is an element of risk in giving choloform, we can only choose the lesser, and so promptly proceed by inhalation to relieve the accessory muscles of parturition of their strain. By the abolishment of pain we lessen the work required of the laboring heart, which, instead of beating at a rate of one hundred and forty or more a minute, may diminish in frequency to ninety or one hundred.

What has been said of fatty heart is equally applicable to conditions of hypertrophy and dilatation.

The equilibrium, if disturbed, is almost certain to result disastrously. That sense of fullness in chest and oppression due to bronchial congestion, if relief is not afforded becomes most distressing. The cyanosis from deficient aëration is greatly exaggerated, while the insufficient blood-supply to the brain causes syncope and may be succeeded by coma if the excessive reflex disturbance be not removed. Nor are the indications for the administration of chloroform materially different in the case of females in labor with valvular disease. Whether it be mitral in the young adult or aortic in the aged primipara the cardiac strain must be relieved if we would save our patient. As is well known, all forms of valvular disease ultimately develop a condition of ischæmia on one side with corresponding low tension, while on the other side is stasis with high tension. While by compensation life may run on for years, yet, when the strain of parturition comes, it will soon be overthrown if precautions are not taken to prevent it.

Of what benefit will be our knowledge of the value of cardiac "physiological rest," as laid down by Fothergill, if we do not apply it under these conditions? We all appreciate the importance of securing "quietude of mind and body" when such pathological states exist. Then why not employ the quickest and safest means to obtain it by the inhalation of chloroform? If the danger is great from "active exer-

cise—climbing mountains, running up stairs, lifting heavy bodies, and all kinds of exercise involving heart strain"—how much greater, aye, how immeasurably so must it be when the parturient female forces, with the anguish of despair, every muscle to its utmost in her desire to deliver her child. From a study of chloroform anæsthesia in obstetric practice we have seen how it should be administered and how it acts. Surely none will deny that in its employment under these circumstances we act otherwise than for the best interest and safety of our patient. That one may not be charged with being a blind adherent to theory, one has only to turn for support and justification to the teachings of the late lamented Fordyce Barker, who states: "It seems to be almost accepted as an axiom, with both profession and public, that the inhalation of chloroform is dangerous to any woman with disease of the heart. For more than thirty years I have been convinced that this opinion is quite erroneous, and I have so taught in my lectures and in former writings."

He goes on further to say: "I have seen several cases, complicated by dangerous heart lesions, which terminated favorably, as I think, solely from the use of chloroform."

Snow, likewise, is of this opinion, "In all forms of valvular disease," he says, "chloroform, when carefully administered, causes less disturbance of the heart and circulation than does severe pain." To quote from Championniére: "If," he says, "I recognized an organic affection of the heart, without pulmonary complications, I should rather give the woman chloroform than to let her suffer." Were further proof necessary as to the propriety of employing chloroform anæsthesia, one might include among this group of clinical observers, Vergeley, who expresses himself thus: "Diseases of the heart are not a contra-indication to the use of anæsthesia." Macdonald states: "In almost all cases of heart disease with labor chloroform has been given, and apparently with benefit, during delivery. If carefully administered I think it cannot but be useful in all cases." Since such eminent authorities advocate its employment can we justify ourselves in refusing our patients the benefit and comfort this agent affords? What is the danger from chloroform compared to the state of exhaustion and collapse into which the parturient female will inevitably fall? If this heart is forced to the verge of paralysis from overwork and excitement, why shall we not use the means at our command to lessen that strain? Let us have a reason for the faith that is in us, and not hesitate to fearlessly employ extreme measures to overcome extreme dangers.

Chloroform by inhalation can and will, if properly administered, save the lives of parturient females, suffering from organic disease, when death seems imminent from over-stimulation of its ganglia through reflex nervous action. Organic heart disease, then, does not preclude the use of chloroform in labor, but rather is a condition calling for its careful administration.

THE TREATMENT OF CYSTITIS BY CORROSIVE SUBLIMATE.

Guyon (*Bulletin Médical*, January, 1892,) reports the good results obtained from the use of corrosive sublimate, in the form of washings or better still by instillation, in the treatment of 26 cases of cystitis. Tubercular cystitis, which is only relieved by a general treatment, seems to receive marked benefit from the use of the bichloride of mercury. The cases of cystitis which are notably benefited by this drug however, are those occuring in prosfrom this ointment, and what was especially remarkable was the marked diminution tatic patients; in such cases the remedy ought not to be employed until the inflammation of the affected organ has subsided. When the capacity of an inflamed bladder is small, then the instillations are to be preferred, for, under these circumstances, the contact of the remedy with the mucous membrane is prolonged, and the injection allowed of larger doses. The solution employed should be, at the beginning, of the strength of 1 to 5,000, this being gradually increased to as high as 1 in 1,000. The instillation must be made on the posterior portion of the urethra, never injecting more than 20 or 30 drops at the beginning of the treatment. Later on 4 and even 8 grammes may be employed, if, however, pain is produced at the enset, the number of drops must be diminished. Before injecting the medicine the bladder should be emptied. The washings may be employed at the later stages of the affection, when there is absence of pain.

ERRORS OF REFRACTION AND THEIR RELATION TO HEADACHES AND OTHER REFLEX NEUROSES.*

By F. R. REYNOLDS, M. D.,
EAU CLAIRE, WIS.

This subject has been so often before the medical profession of late, that I feel I almost owe an apology for again bringing it to their notice. My only reason for so doing, is that I may emphasize its importance and impress the necessity of a thorough examination of the eyes when no other methods of treatment succeed in effecting a cure in obscure nervous troubles. By a thorough examination, I mean one in which the accommodatiou has been paralyzed by a mydriatic, so that the entire amount of refractive error, both manifest and latent, may be ascertained.

That there is often a wide difference between manifest refractive error, and the entire amount as brought about by the paralysis of the accommodation, I shall show by citing a number of cases from my own practice.

Very often in the young, there is not only no apparant error of refraction, but by a spasm of the accommodation, hypermetropic eyes often show an apparent myopic condition, and myopic eyes show an increased degree of myopia. Patients often come to us with the complaint that their eyes are weak and they think they require a little strengthening eye wash; when judicious questioning often develops the fact that they have been subject to headache, more or less, for a number of years, and the letters sometimes blur after continued reading. Such patients will scoff at the idea of requiring glasses, claiming they can see "as well and as far as anybody."

Although in childhood while the power of accommodation is still good, constant close work is possible to these cases, it grows more and more difficult as the range of accommodation diminishes with advancing age: or this condition may be brought on in children as a result of severe disease or after excessive ocular strain.

The power of accommodation may be maintained for a certain length of time, then it relaxes, the letters become indistinct, objects become confused, the eyes begin to smart and to burn, and if work is continued pain in the eyes and head result. The pains often assume a neuralgic form, but after their long continuance the headaches sometimes become independent in character and persist after the strain is removed. Treatment in such cases is of no avail until the ciliary irritation is relieved. It is not until then, that the remedies indicated produce their effect. The patient may not show any refractive error upon examination by means of the trial case; but by retinoscopy, or after the accommodation has been paralyzed by a mydriatic, a decided and sometimes very considerable degree of ametropia is discovered.

I have known cases to show no error of refraction at all, or only a slight degree, that by retinoscopy or after preparation by a mydriatic have shown as high as 2.50 to 3.00 D.

In a paper read by Dr. Dana, Prof. of Nervous Diseases in the New York Post Graduate Medical School, "On Chronic Headaches of Functional Origin," we find the following: "At the present time the eye is credited with giving rise to an immense number of head pains.

"Their location depends, not only upon the pathological condition of the eye, but also upon the constitution and occupation of the patient. From my investigations, it seems to me that the most general rule which one can formulate is that headaches of refractive errors are usually frontal or orbital, those from muscular insufficiencies are more often occipital and cervical."

And it is here pertinent to remark that Prof. Dana is not a specialist in Ophthalmology.

Meyers in his work on diseases of the eyes says: "Again, patients never fail to tell us that they do not see so well near at hand, as at a distance, and that their eyes get tired very easily when their work requires close application. This feeling of fatigue in the eyes is accompanied with pains in the peri-orbital region and sometimes with headache. This is a symptom which at once sets us on the track of the diagnosis."

*"In writing of Habit Chorea, de Schweinitz wishes to emphasize the fact that if the habit spasm especially affects the mus-

* *Read before the Inter County, Med. Society at New Richmond, Wis., March 8, 1892.

* An. of Univ. Med. Sci. 1889, B. 60.

cles of the face, particularly those around the eyes, the following points deserve attention:

1st. The condition of the refraction and the muscle balance should be carefully examined.

2nd. The anomaly of refraction under complete ciliary paralysis, and the full, not partial, correction ordered.

3rd. This correction should be employed in conjunction with proper internal medication and general hygiene and not to the exclusion of these measures."

* "Gould reports a case of chorea in a girl, that, without, amelioration, had been treated for two years in a hospital with large and long-continued doses of arsenic.

This treatment was discontinued upon ordering spectacles, and within three weeks after the correction of her compound hyperopic astigmatism the chorea entirely disappeared, (not returning in six months) and with it likewise her headache, dizziness, violent bursts of temper, etc.

† He also calls attention to the influence of errors of refraction upon developing character and vocation in life. The subtle influence of even slight eye-strain may in the young work deleteriously upon the disposition and the mental life, or slowly turn them from occupations otherwise chosen."

‡ Colburn gives the case of a minister, who, upon account of frequent epileptic seizures and mental disturbance associated, with inability for use of eyes, had, after eight years of suffering; an insufficiency of the external recti muscles treated by exercise with prisms, and an hereditary hypermetropic error of refraction carefully corrected with proper glasses.

From this time the patient gradually improved, until, at the date of the report, he had had no seizures for more than one year, and his mental condition had become so much better, that he was, to use his own language, "able to do a good day's work without any symptoms of his old trouble."

‖ Based upon twenty observations, George Martin, in an article entitled "Ophthalmic Migraine and Astigmatism," deduced the fact that bilateral migraine always is the greater on the same side as the stronger contraction of the ciliary muscles, and that relief is afforded by the use of the correcting lenses.

Six cases of migraine were met with in the practice of Percy Jenkins, five of which showed hypermetropia from one to two dioptries, and one, myopia of 2.25 D.

Correction of the refractive error was followed by absolute cure in every case."

* "Among sundry neuroses Harper reports the details of two cases of obscure but varied mental trouble due to hyperopic and astigmatic errors, that disappeared at once on their correction.

Hewetson cites illustrative cases of insomnia and general symptoms usually called hysteria, such as tenderness of the spine and skin generally, great nervousness, etc., that were distinctly traceable to irritional eye-strain. Gould describes a case of extreme rapidity in the cardiac action (130 beats per minute) that had resisted other therapeutic attempts for several months, (which had come on after prolonged reading at night,) and that was followed by loss of health, flesh, etc.

With a correction of the existing astigmatism, there was a speedy reinstatement of normal conditions."

The following were selected from my case-book as illustrative of some of the conditions mentioned in this paper:

Case I.—Miss. H. T., Stillwater, Minn. Consulted me Sept. 25, 1885. She came to me, her eyes filled with tears, and so overcome by her feelings that she was scarcely able to speak. She told me she was sure she was going blind, sooner or later, and that she was completely discouraged.

Her symptoms, in her own language, were as follows: "My eyes have always been weak, and I have been subject to sick-headache ever since I can remember. I often have to go to bed and lie the entire after noon the pain in my eyes and above them is so severe. At times, I get so dizzy as to nearly fall, and then everything gets black in front of me, and I think I am surely going blind; but usually, after a night's rest, the symptoms disappear, and I feel encouraged again, only to go through with the same pain and suffering, upon the slightest use of the eyes."

She said she had taken medicines for her headache ever since she could remember,

*An. of Univ. Med. Sci., 1889, B. 33.

but nothing ever produced any lasting benefit. I told her to take courage as I thought I could bring her out alright.

After a thorough paralysis of the accommodation, I found her refractive error to be as follows: viz—

R. E. +3.00 D.Sph. ⊂ +1.25 D. Cyl. Ax. 90°

L. E. +3.00 D. S. ⊂ +1.25 D. Cyl. Ax. 60°

I gave her full correction and advised her to wear her glasses constantly.

Under date of Feb. 23, 1892, she writes as follows: "As soon as I got my glasses from you my trouble began to subside, and in a short time I was entirely free from my headache and other unpleasant symptoms.

"I am very grateful to you, as I can now do any kind of work with my eyes, day or night, and am not troubled in the least.

"Could not possibly get along without my glasses, for at times, I have tried to do so, but cannot read more than a few minutes before my eyes commence to pain."

Case II.—Miss M. Z.. æt. 17, St. Paul, Minn. Called Sept. 17, '89. Strabismus, L. E. 21–2 lines. Subjective symptoms as follows:—Has pain in the head and eyes when used excessively. Pain commences in the eye-balls and shoots through the head. Has frequent attacks of nausea and dizziness.

Vision R. E. $\frac{20}{40}$ L. E. $\frac{1}{20}$ with +1.00 D. S ⊂ +

.25 D. Cyl. Ax. 180° for R. E. V= $\frac{20}{20}$

With +2.00 D. S. ⊂ +

.25 D. Cyl. Ax. 180° for L. E. V= $\frac{20}{20}$

Under mydriatic, refractive error discovered was as follows:—

+2.00 D. S. ⊂ + .25 D. Cyl. Ax. 180° both eyes.

Corrected strabismus and prescribed above combination with the result of entirely curing trouble.

Case III.—Miss M. C. Menomonie, Wis. Aet 18 years. Consulted me August 27th, 1885. Subjective symptoms:—Holds her book very close to eyes. Constant headache while studying. Complains of nervousness and insomnia. Vision, $\frac{20}{70}$ both eyes.

Before using mydriatic I found the following combination of hypermetropia and myopic astigmatism. R. E. +2.50 D. S. ⊂ —3.00 D. Cyl. Ax. 10°. L. E. +2.50 D. S. ⊂ +2.75 D. Cyl. Ax. 170°.

After using mydriatic, R. E.= + 5.00 D. S. ⊂ —3.50 D. Cyl. Ax. 10° L. E.= +5.00 S. ⊂ 3.50 Cyl. Ax. 170°.

These glasses entirely relieved patient of all headache, nervousness, and insomnia.

Case IV. Mrs. A. J. A., Rock Elm, Wis., æt 35 years, consulted me Jan. 20, 1890. Subjective symptoms given at the time read as follows:—Eyes often get dim while reading or sewing. Great pain in periorbital and frontal regions after continued use of eyes. Has frequent attacks of "blind headache." Vision: R. E. $\frac{20}{30}$+, L. E. $\frac{20}{30}$

Manifest hypermetropic astigmatism is as follows:

R. E. +.50 D. Cyl. Ax. 90°: L. E. + .75 D. Cyl. Ax. 90°.

With the above correction V. was $\frac{20}{20}$

After use of mydriatic a compound hypermetropic astigmatism was revealed.

R. E. +2.50 D. S. ⊂ +.50 D. Cyl. Ax. 90°.

L. E. +2.25 D. S. ⊂ +.75 D. Cyl. Ax. 90°.

Full correction was given with immediate relief, and after three weeks all pain and headache had disappeared.

Case V. Mrs. P. A. L., Spokane Falls, Wash., æt 50 years, consulted me August 26th, 1889. Subjective symptoms given as follows: Eyes been weak for 25 or 30 years. Has frequent attacks of nervous headache. Worn glasses 20 years, but never was fitted by an oculist, and never wore glasses for distant vision. V.=$\frac{20}{40}$

Without use of mydriatic, the following refractive error was discovered:

O. D. +1.75 S. ⊂ +.75 C. Ax. 70°.

O. S. +1.75 S. ⊂ ×.50 Ax. 160°.

With this correction V. was $\frac{20}{20}$

I prescribed biocal glasses with above combination for distant vision; and the addition of +2.75 S. for reading, with very happy result; as she writes me under date of Sept. 20th, 1891., that "she can use her eyes all day without pain or discomfort and she is entirely cured of her nervous headache."

Case VI. F. C., Crookston, Minn. Aged 8 years. Came to me Dec. 15th., 1888. Has had chorea two years, since first commencing to attend school. She is weak and anæmic, and complains of always being tired. First symptoms manifested were twitchings of the eyelids and face, which were soon succeeded by characteristic jerkings of the legs and arms, and at times inability to maintain her equilibrium in walking.

Added to these symptoms were severe

attacks of headache; periorbital and frontal. She was removed from school and treated with tonic remedies: iron, strychnia, arsenic, and finally by electricity with beneficial results, and apparent cure; but upon returning to her school work, the trouble would again manifest itself; and so continued until she came under my care. She was brought to me on account of "Blepharitis Marginalis" which had also existed for two or three years.

After obtaining a history of the case, an error of refraction immediately suggested itself.

Upon examination no manifest error was discovered, but after obtaining complete ciliary paralysis she showed;

R. E. +2.75 D. S. ⌒ +.50 D. Cyl. Ax. 70°.

L. E. +2.75 D. S. ⌒ +.50 D. Cyl. Ax. 160°.

I gave her full correction to be worn constantly; also gave ointment for application to edges of eyelids.

She began to improve almost immediately the nervous phenomena manifesting themselves less and less frequently until at the end of three months they had ceased altogether and have not since returned.

*Goode in an article on "Headaches due to Disorders of Vision" believes that the increase in the number of spectacles worn is not to be regarded as an evidence of modern degeneration of the eyes and threatened further alterations unless we call a halt in some of our ways but rather that a long-felt necessity has been met.

Although I fully agree with Goode in the above, in addition I feel called upon to say, that in my opinion, the present system of education, has a great deal to do with developing these various nervous and mental disorders. The too rapid advancement in the education of the young, and the habit of placing so much of the work upon the black-board, from which the pupil is required to recite and to copy: the blackboard work being to my mind especially pernicious.

TREATMENT OF HEMORRHOIDS BY CARBOLIC ACID INJECTIONS.*

By J. W. Hallum, M. D.

CARROLLTON, GA.

The treatment of hemorrhoids by carbolic acid injections, is a treatment that I hesitate to present and advocate before this association, not because of any of its defects, but on account of its opponents.

To Colles of Dublin has been accorded the honor of first treating piles hypodermically, in 1874. Dr. S. H. Sturgeon, of this country, claims that he reported cures by the carbolic acid injection in the *Medical Brief* for 1874. There was but little attention given the subject before Dr. W. P. Agnew, of San Francisco, reported his cures by the treatment in *The Toledo Medical and Surgical Journal* in 1877. In 1880 Dr. Blackwood, of Philadelphia, reports his cures by it in the *New York Medical Record*. Since that time there have been volumes written on this subject.

Therefore I do not expect to introduce anything entirely new, but I do hope that I may be able to interest some of you who have not been making satisfactory cures of this very common disease.

Why you have not I shall not attempt to explain, but describe my mode of procedure in a country practice, where the office is unhandy, and an operating table or chair unknown.

It is not necessary to be a specialist in order to be successful in the treatment of piles by this method. By it quacks have succeeded admirably and made inroads on our practice?

The cure of this disease is comparatively unknown by the average physician. Are we not too often neglecting the more common diseases for the more rare? Therefore, I have offered no apology for claiming your time and attention for a few minutes.

It is not the object of this paper to give definitions, symptoms and varieties of hemorrhoids. I know of no reason why I should discuss the pathological anatomy of pile tumors; for they are all alike amenable to this treatment, whether recent or of long standing, venous or arterial origin, blind or bleeding, external or internal.

*Read before the Georgia State Medical Association April 22d, 1892.,

Hemorrhoids are sometimes complicated with abscess, ulcer, fissure, fistulæ and prolapsed rectum.

The works of Kelsey, Allingham, Smith and others give all the discriminating points of diagnosis, and I would respectfully refer you to them for such information. It is absolutely necessary to make no mistake in diagnosis when we go to apply the carbolic acid treatment. Because I am satisfied it would be unsafe to inject a prolapsed rectum or other healthy tissue with carbolic acid.

Piles are uncommon in either sex before puberty, and I have never yet seen one in children. However, Mr. Bryant in his Surgery on page 533 speaks of a treatment and says it is alike beneficial to child and adult.

I know of no cause of hemorrhoids that would contra-indicate the use of carbolic acid treatment. Yet I would not urge this mode in all cases without regard to the patient's previous history. We are often applied to for treatment for piles when there is really no pile—nothing more than an irritated rectum, caused by straining, diarrhœa, a night's debauch or the presence of some foreign substance. Such cases will readily yield, generally, to hot water enemata administered two or three times daily.

There is another class of cases that I always advise to "wait for a more convenient season" to receive treatment. These are cases of pregnancy. The household syringe will render these also bearable until her term is passed, and then if her piles continue we should advise her to have them treated.

But in most cases that apply for relief it is unnecessary to delay, but proceed at once to make cure of the pile tumor. We do this by mixing together pure carbolic acid one part, and pure glycerine two parts, and enough morphine and tannic acid that ten drops of mixture will contain one quarter of a grain each. Let this be thoroughly dissolved before using it.

I will not describe all the positions in which a patient may be placed for this operation. It is so simple that it can be done in any position that will command a good view of the tumor.

The position that I have found to be probably the best is the one in which a toad assumes when in a sitting posture. In this position the patient will almost invariably pass out the tumors by an effort at straining down. However, if he should fail then by gently manipulating with the fingers the contraction of the anal sphincters will be overcome and allow the tumor to readily pass out. When operating in the office I use a table about 18 or 20 inches wide, 30 inches high, with a stool at one end. The patient steps on the stool with the knees and lies down on the table, the face downward, this is a splendid position for this operation. For obvious reasons we select the tumor highest up the rectum for first injection. We then insert the needle at right angle to the base of the tumor near its base, and let the deposits be made at different places by moving the needle as the process of injection takes place. Allow the needle to remain in position till the blood of the tumor is coagulated which will be accomplished in about half a minute. Then the tumor is reduced when possible, well greased, and the operation is complete for that time. There is more or less burning for a few minutes consequent upon the injection, after which in the course of five or six days the tumor begins to throb and ache from the swelling and also the death of the pile itself. This pain will continue generally from one to not over fifteen hours. The latter is in case of a large external irreducible tumor. In about three or four days the sloughing is complete leaving a granulating surface which heals rapidly. After the healing process is complete the next tumor may be treated in a similar way to the first and so on till all have been destroyed.

We prefer to inject the tumor while it is engorged, in which case the pain is not increased but actually diminished. I have never yet needed a speculum or any other instrument except the hypodermic syringe to do this operation successfully.

We will suggest that not over two or three small tumors be injected at a time, and not over one when it is very large, because of the swelling consequent from the operation. Patients seldom suffer more than they do at any other time from a fit or paroxysm of the piles.

We would advise our patients not to indulge in any physical exercise that requires much effort, but ordinarily they are able to be up and do light work all the while.

Nothing more than a gentle laxative should ever be used for the bowels.

For the last ten years this plan of treat-

ment has never produced any alarming symptoms—no secondary hæmorrhage and sloughing except the pile itself. By it I have yet to report my first failure. By this mode Drs. E. J. Dennis of Kansas City, Fred R. Boyd of St. Joseph, Mo., Q. A. Shufford of Tyler, Texas, W. L. Rodman of the University of Ky., have cured their hundreds. While W. P. Agnew of San Francisco, Ivies and Davis of Chicago, Kelley of Cincinnati, Monroe of Louisville, E. F. Hoyt of New York, have cured their thousands.

BORATE OF SODIUM IN THE TREATMENT OF EPILEPSY.

According to Mairet (*Le Progrés Médical*, February 6, 1892) the use of borate of sodium demands on the part of the therapeutist, certain precautions. The physiological action of borax is so pronounced, that in certain cases it becomes necessary to suspend it, notwithstanding the good results to be obtained from its use. The remedy exercises its action upon digestion, nutrition, and the skin. On the digestive tract it produces such phenomena as nausea, salivation, a considerable loss of appetite, a dislike for food, and sometimes vomiting and diarrhœa. Upon nutrition it sometimes causes a slight diminution of the bodily weight; but in some cases the emaciation is quite marked, and may be accompanied with swelling of the face, œdema of the extremities, and diarrhœa, giving rise to the production of a true alkaline cachexia. Between these two extremes, the whole range of the disorders of nutrition may be observed. Under the skin, borax produces various eruptions, notably the papular, the eczematous, the scarlatinous, the rubeolic and the furuncular. In administering the drug small doses must be employed at first, that is from 0.50 grammes to 1 gramme, which may be increased gradually, according to the tolerance of the digestive tract. When 8 grammes are insufficient to completely arrest the attacks, it may be concluded that larger quantities are of no advantage. In a general way, with the exception of certain cases, the maximum dose of borax, from which good results may be expected, may be set down as 10 grammes during the 24 hours. When the beneficial limit of the action of the drug has been reached, the doses employed should be diminished.

SOCIETY REPORTS.

CLINICAL SOCIETY OF LOUISVILLE.

Stated Meeting, April 5th, 1892.

P. Guntermann, M. D., President, in the Chair.

RECURRENT PERITONITIS.

Dr. W. H. Wathen:—Referring to the case of recurrent peritonitis reported by Dr. L. S. McMurtry at a previous meeting, it has been my experience that frequently in these cases, there are severe pains in one or both legs; and, I have often had cases where the nutrition of both limbs was much impaired, with cold clammy perspiration, where but one side of the adnexa was involved. But, generally, these disturbances occur in the leg on the side where the tube or ovary is diseased, and they are various, probably sometimes with symptoms of histroneurosis, which will explain the drawing up of the leg in the case reported. These troubles often occur where there is nothing more than simple adhesions which are easily separated, as in the case described, with no pus or hard exudate. There is no way of curing these cases except by surgical interference, and the results are very gratifying. In the case reported the operation was not entirely complete, because nothing was done to prevent the uterus returning to its retro-placed position. It is the safer plan to get permanent results, to fasten the uterus in front by some of the methods devised for that purpose. Formerly to accomplish this, I have used a silver wire, which I do not intend to use again; I will substitute kangaroo tendon and fasten the round ligament and broad ligament to the parietal peritoneum on each side of the abdominal incision. This is the safest and quickest method, and, there is no trouble resulting from it. You might probably do a more artistic operation by suturing the broad ligament and round ligament to the anterior surface of the uterus, thereby shortening these supporters so as to hold the uterus in its proper position. It is bad surgery to attempt to separate the adhesions and replace a retroposed uterus without doing an abdominal section. It does no good and it may do much harm, or cause the death of the patient. There

may be small cavities of pus in the pelvis that no laparotomist is able to diagnosticate until the abdomen is opened, which forcible efforts at replacement might rupture and kill the woman. Adhesions cannot be separated by this method, and a laparotomy will finally have to be performed. I have dilated the womb frequently, and my name is very widely known in this connection, because of an instrument I devised some years ago for this purpose, and which is now manufactured and used in this country and Europe. I have never caused peritonitis by dilatation, but have learned that peritonitis often follows dilatation in the practice of some physicians, even when dilatation is not carried to any considerable extent. I have under treatment a patient with a pus cavity emptying into the rectum, caused by dilatation of the cervix by one of our prominent physicians. I do not think that dilatation of the womb, either extensive or moderate is justified if there are any adhesions.

PELVIC REFLEX TROUBLES.

I will report a case I operated upon about four or five weeks ago, with unusual reflex troubles. Her physician had been giving her three-quarters of a grain of morphia and one-fiftieth grain of atropia three or four times a day hypodermatically. She would get nervous and her pulse would increase in frequency and gradually run up from 80 to 140 per minute; her face would get as red as the blush of scarlet fever; around her neck the skin would be perfectly white; on her arms and body there would be spots two or three inches in diameter, the color of the face, and separating them the skin would be absolutely bleached. In other words, on parts of the surface of the body, there was paralysis of the capillaries, with capillary contraction in the intervening spaces. This would last from two to five hours, coming on sometimes twice daily. I removed an embedded broad ligament cyst, and separated extensive tough adhesions. There was considerable bleeding and a drainage tube was used for two days. She had no outward symptoms from the operation, her pulse and temperature remaining normal. After the operation there was no recurrence of these blushes, until two weeks ago when a friend slipped and fell, striking with her arms upon the abdomen of the patient. The shock caused severe pain and the morphia, which had been reduced to about one-eighth of a grain per day, has since been increased to from one-quarter to one-half grain daily; her reflex disturbances have returned, but her pulse has not gone above 115 per minute. It may be necessary to do another laparotomy and remove the ovaries and tubes, which were separated from adhesions and not removed, because not badly diseased.

SYPHILIS.

Dr. J. W. Irwin: I bring before you to-night a patient that does not look at all sick, as you will observe. This gentleman fifteen years ago had a small sore on his penis, which was diagnosticated by the physician who attended him at the time, as a soft chancre, which healed up rapidly. He first came under my observation on the 8th day of August, 1890. He was then suffering from pharyngitis, with induration of the soft palate. There were no evidences of constitutional disturbance, no enlarged glands and no eruption of the skin. The throat was not ulcerated, but from its appearance and the indurated condition of the soft palate, I gave the opinion that the trouble was syphilitic, which opinion was not concurred in by the patient. He remained under my treatment until about the 19th of November, 1890, when the throat trouble had yielded to specific medication, and, then, passed from under my observation until early in the spring of 1891. During the interim from the time I saw him, until he returned, he had a series of experiences, which he can tell for himself. Soon after his return I was called to see him and found him suffering from partial hemiplegia, and severe hemicrania. I made a further examination and found that he had nodes on the clavicle and sternum, and there were evidences of similar deposits within the skull; vision was imperfect; a supra-trochlear gland had suppurated. He had gained in flesh and in strength under the treatment I had given him, still, he was not satisfied and sought advice elsewhere. His sight grew worse, and as it did not improve under the treatment he received here, he went to Chicago and there consulted an ophthalmologist who told him that he would never again regain his sight; he was now entirely blind and had to be led. He then went to

Milwaukee and sought the advice of a prominent specialist, who told him that he thought he had about one chance in a thousand of regaining his sight, but, he would not undertake the case unless he could remain with him a year. Very much discouraged and blind he then returned to Chicago and put himself under the care of another physician who concurred in the diagnosis that I had made, and prescribed similar remedies. He came under my care again on the 29th of December, 1891. I found him taking 125 drops of a saturated solution of iodide of potassium three times a day, and his sight had improved enough to enable him to find his way without assistance. I advised that the dose be increased to 150 drops and the improvement continued much more rapidly. As the dose was well borne, soon after I advised that it be increased to 180 drops. Meantime he had gained in weight under these enormous doses from 180 pounds when he commenced the treatment to 267 pounds. One eye is now so far improved that he can see to read, and he can see his hand when passed before the blind eye.

The peculiarity of this case was in the difficulty of diagnosis at first. The induration of the soft palate which would not yield to treatment, led me to believe it was a case of syphilis, notwithstanding the fact that there was nothing in the history indicating that he had contracted the disease. Then, when the supra-trochlear gland became inflamed, I was more than ever convinced that it was syphilis. Finally the appearance of nodes and trouble with his eyes, pointed unmistakably toward syphilis.

Dr. W. O. Roberts:—What effect did the iodide of potassium have upon the kidneys? Did it increase the flow of urine?

Dr. J. W. Irwin:—Did not notice any change. He is taking now 180 drops three times a day. The stomach seems to stand the dose very well.

Dr. W. O. Roberts:—This shows that large doses of iodide of potassium can be given in these cases. There are several members present who are well acquainted with a patient, but not with the treatment, that I will mention in connection with the case reported. It was a young man who had syphilis, and had every evidence of involvment of the brain. He was treated by Dr. Bodine and myself, and we gradually increased the dose of iodide of potassium as done in the case related by Dr. Irwin, until the patient took one half ounce (240 grains) three times a day. We noticed after giving these large doses it produced most copious diuresis, the patient passing enormous quantities of urine. His symptoms yielded to the treatment, then the dose was was gradually diminished. I do not remember for what length of time the enormous doses were continued, but for a long time. It has now been fifteen or sixteen years, and there has been no evidence of syphilis since then.

Dr. T. Satterwhite: I have often spoken of the case referred to by Dr. Roberts as the criterion for large doses of iodide of potassium. Dr. Pusey and myself had a case several months ago, in which there was cloudiness of the cornea, and total loss of sight of one eye. It never yielded to any treatment except enormous doses of iodide of potassium—he took about 200 grains a day and has improved ever since. His restoration to sight is progressing, he is now able to tell the number of fingers you hold up. I believe in large doses of iodide of potassium in syphilitic diseases.

Dr. J. A. Ouchterlony: I was very much interested in the case, especially because of the obscurity of the diagnosis. We all know especially in cases of syphilis, where there are early symptoms, we may expect various secondary troubles later on. While toleration of large doses of iodide of potassium may be evidence that it is a syphilitic trouble, still, I do not think the opposite will hold good. One does meet occasionally with syphilitic patients who cannot tolerate iodide of potassium; these are exceedingly troublesome cases. I have one of that kind under my care at the present time. In it there is a history of syphilis, with very marked early secondary symptoms, and three years later very extensive glandular enlargements, sufficiently characteristic of Hodgkin's disease to make it a little doubtful whether the patient did not have that. The blood was examined, however, and found to be perfectly normal with the exception of a slight diminution of hæmoglobine. In this case which was undoubtedly syphilitic, doses of sixteen grains of iodide of potassium three times a day gave rise to such unpleasant effects, that it was necessary to diminish the dose. I believe in this case a sojourn at Hot Springs would do good. Possibly we could get beneficial results by carrying out a

"Hot Springs'" treatment as well as practicable at home; for instance, large doses of silurian water, and making him take a Turkish bath three or four times a week. Under such circumstances, I think we could make persons who are intolerant of full doses of iodide of potassium take large doses, when, ordinarily they would not be able to do so.

Dr. W.O. Roberts: Have you ever used digitalis in connection with the treatment of syphilitic cases?

Dr. J. A. Ouchterlony: Never, unless there were some evidences of cardiac disturbance with it.

Dr. A. M. Vance: I am surprised that Dr. Irwin did not say anything about giving his patient mercury. I do not believe that the tolerance of large doses of iodide of potassium is proof of syphilitic condition. I have seen a number of cases like the one Dr. Irwin described, that have responded after long treatment with iodide much better when mercury was added.

Dr. W. C. Dugan: I have read of a number of cases of syphilitic nature where calomel was used with very gratifying results.

Dr. W. Cheatham: I understand that mercury can be given by the skin with beneficial results, in cases of syphilis, where patients are unable to take it by the stomach.

Dr. J. W. Irwin: I hardly thought it necessary to go into details concerning the treatment of this case, but remarks would indicate that something on this subject may be said. When this gentleman came under my observation with pharyngitis, I could get no history of syphilis, and when I approached the subject, he denied having had anything of the kind, even the sore. I informed him that I thought he had syphilis, and there was no doubt in my mind that the condition of his throat was syphilitic. The throat trouble would yield to no treatment until I commenced the use of mercury. I gave him mercury by the mouth with very little effect. I then used the method of Lewin and gave injections of one-sixth grain corrosive sublimate hypodermatically, which caused the induration to melt away like snow. I continued this treatment every second day until he had received sixteen hypodermatic injections of one-sixth grain corrosive sublimate. I might say that the corrosive sublimate produced a very decided effect upon him; it caused vertigo to the extent that he would have to lie down for about half an hour after each injection. Then his skin would become a healthy pink color and normal feelings would return to him. Now, one word in regard to the use of iodide of potassium: I have never treated a case of constitutional syphilis depending upon iodide of potassium alone with the hope that the patient would remain permanently well. There is but one thing, in my opinion, that will cure syphilis, permanently, and that is mercury. Under the use of mercury combined with iodide of potash, or, given alone, I think we may expect the most beneficial results.

Diverticulum of Œsophagus.

Dr. J. A. Ouchterlony:—At a meeting of the Society some time ago, a case of intestinal diverticulum was presented, which interested me, and, in looking over some of my foreign journals, in connection with this subject, I came across a case that I shall be glad to read. It is a case of diverticulum œsophagus:

"Mattie B., aged forty-one years: She was admitted to the Seraphim Hospital, Stockholm, on the 24th day of July, 1890. Father died at the age of about fifty years of inflammation of the lungs, her mother died about the same age of consumption. Three brothers and sisters still living, of these two are in good health, one suffering from rheumatism. Four have died during infancy. One sister died at nineteen years of age in parturition. The patient has been married twice, her first husband died four years ago of consumption after suffering many years, and, in this way, causing her a great deal of care and trouble. She has had three children of which the first is still living and in good health, two died about three years of age. During childhood the patient had whooping cough, measles, diphtheria, and at the age of twenty she had a severe attack of typhoid fever, and somewhat later an attack of muscular and articular rheumatism. At times she had been suffering from a cough, but has never had any more serious chest trouble. No disturbances of the digestive organs have been observed. Menstruation has been regular but somewhat abundant. Four years ago she was admitted to the hospital on account of internal hæmorrhage. Her last pregnancy occurred thirteen years ago. The hygienic surroundings under
